— AT a recent meeting of the Linnean Society Mr. F. Darwin read a paper on the relation between the BLOOM OF LEAVES AND THE DISTRIBUTION OF THE STOMATA. "Bloom" on leaves is used by him to mean a coating of minute particles of a waxy character, which is removable by hot water or ether. But gradations occur from a distinct and appreciable greasiness throwing off moisture to such as are easily wetted. A large series of leaves of different groups of plants have been studied by him, and for convenience in the analysis of data he has divided them into four classes. Leaves of Class I. are devoid of bloom on both surfaces, and yield 54 per cent. which have no stomata on the upper surface. In Class II. bloom is deficient above but present below, whereof 83 per cent. contain stomata on the leaves' lower surface. Class III. possesses bloom on the leaves above, but none inferiorly, and 100 per cent. of these have stomata on the upper surface. Class IV. have leaves with bloom on both surfaces, 62 per cent. of them having stomata above. From such analyses and other facts and data given, Mr. Darwin concludes that the accumulation of stomata accompanies that of bloom, and, other things being equal, that it is functionally protective against undue wetting by rain, and thus injury to the leaf-tissue.

— AN exceedingly interesting HYBRID ORCHID flowered last week in Messrs. J. Veitch & Sons' Chelsea Nursery—namely, *Phalenopsis intermedia*, obtained from a cross between *P. amabilis* and *P. rosea*. *P. intermedia* has long been regarded as a natural hybrid between the two species named, and the experiment was undertaken to prove if the opinion was correct. In the admirable paper read before the Orchid Conference, Mr. Harry J. Veitch gave some account of this plant which is worth repeating. After referring to the interest attaching to the plant raised from seed of this cross, he remarked, "The plant had made three healthy leaves, it was well established in a small pot, which, to be more secure from danger, was placed upon an inverted pot that stood in a pan of water. One morning, to the great dismay of Seden, it was discovered that a slug had eaten off two of the best leaves, and would, if not trapped certainly devour the remainder. Anxious to save the treasure, the plant was watched incessantly for hours in the expectation that sooner or later the marauder would make his appearance; to induce him to do so the mass was constantly plunged into water; the repeated duckings had at length the desired effect, the culprit issued from his lurking place, and the plant was saved." This has now flowered, and proves to be the true *P. intermedia*, a good variety of dark colour, the two wings of the lip being of similar colour to the central lobe. Numbers of introduced Orchids are reputed natural hybrids, but we believe this is the first that has been artificially proved, and is, moreover, the first hybrid *Phalenopsis* that has flowered.

— MR. ANDREW SPIERING, nurseryman, Bergedorf, Hamburg, formerly of the Bay of Plenty Nursery, Tauranga, Auckland, New Zealand, sends the following:—"In answer to 'M. C. B.' in the last number of the Journal, respecting a NEW ZEALAND PLANT, I may

inform him that Kowhai-nguta-kaka is the native name for *Clianthus puniceus*, meaning the beak of the parrot, alluding to the shape of the flower; the colonists call it therefore Parrot's Beak, and also Lobster Claws on account of the bright colour of the flowers. *Clianthus puniceus* is considered a native of New Zealand, but I never remember seeing it in its wild state during a stay of seventeen years in the colony, though it is such a remarkable plant that a gardener would hardly overlook the same. When found wild it is on old native settlement, and from this fact it is more likely that the seeds were brought by the Maories from the South Sea Island on their landing in New Zealand; they brought several other roots and seeds with them and are still cultivated. The Kumera or Sweet Potato (*Convolvulus batatas*), Taro (*Caladium esculentum*), the Calabach (*Lagenaria vulgaris*), and perhaps others. The late Venerable Archdeacon Brown, an old missionary, who travelled through the greater part of the Northern Island, told me that he only met the *Clianthus* at native villages or such places that had been formerly occupied by natives. Another native plant of New Zealand called Kowhai is *Edwardsia microphylla*, a tall evergreen tree, very often seen. The colonists call it also the Kowhai Tree; it has bright yellow flowers; the name alludes to the shape of the flowers—a beak. The description and culture of *Clianthus puniceus* (English Glory Pea) is found in most garden books, but the native name is perhaps less known."

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS at Hodsock Priory, Worksoop, Notts, for February, 1886:—Mean temperature of the month, 34.3°; maximum on the 13th, 48.8°; minimum on the 7th and 27th, 20.7°; maximum in sun on the 26th, 93.9°; minimum on grass on the 27th, 13.0°. Mean temperature of the air at 9 A.M., 33.1°; mean temperature of soil 1 foot deep, 35.7°. Nights below 32° in shade nineteen, on grass twenty-five. Warmest day the 14th, coldest day the 7th. Total duration of sunshine in month, forty-seven hours, or 17 per cent. of possible duration; twelve sunless days. Total rainfall, 0.39 inch; maximum fall in twenty-four hours on the 18th, 12 inches. Rain fell on twelve days. A very cold and dry month, with average sunshine. Both day and night mean temperatures are 2½° lower than any of the previous ten years, and are also lower than in January. In no former year have we had less than 1 inch of rain in February. Vegetation shows no sign of spring growth at present.

#### STRAWBERRY PLANTS IN WINTER.

I HAVE only just observed "A Northerner's" remarks on this subject, page 111, or should have replied earlier. The time I generally stack the plants in the autumn is the first week in November, and they are taken out of the ashes and placed in an upright position some time in March, provided the weather is not too wet nor too severe. I have never yet found them suffer from dryness during this period, because the ashes, as well as the soil in the pots, absorb sufficient moisture to keep them perfectly healthy and fresh. The average rainfall here during the above period is 12 inches, and as the situation is extremely low, damp, and sheltered, the evaporation is but little. I have frequently plunged a few plants in an upright position for experiment, and have never found them after wet winters in such a satisfactory condition as those stacked in ashes. It has been said that plants wintered in this manner lose their roots and are less vigorous, but I cannot say that I have ever found this to be the case. I do not, as a rule, attempt to grow large fruit, but when required find no difficulty in obtaining fruit in April and May from 1½ to 2 ozs. each, which I imagine could not be easily obtained from plants in a weak or rootless condition.—T. CHALLIS.

#### ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW.

ON Saturday last a meeting of gentlemen interested in horticulture was held in the Town Hall, Liverpool, for the purpose of considering arrangements for the forthcoming Exhibition. David Radcliffe, Esq., Mayor of the city, presided, and in his opening speech said he should be pleased to do all that lay in his power to render the Exhibition of the "Royal" a success. Resolutions were passed for the purpose of getting up the guarantee fund of £1500. To carry out this object a Committee was formed, and the names of some eighteen or twenty gentlemen were enlisted with power to add to their number. The Mayor was elected President, Enoch Harvey, Esq., Secretary, and H. Gaskell, Esq., Treasurer. A very good start was made with the guarantee fund, for the list after being passed round the hall included the names of the majority of the gentlemen present for £25 each. The number of letters read from those not present also testified to the hearty manner in which the visit of the Royal is entertained.

I do not doubt that the "Royal" will cover as much ground in their schedule as they possibly can, but it would be very difficult to form any idea of the extent or even the variety of the Exhibition from the remarks made by Mr. Harvey, who appeared willing to leave this matter in the hands of the officials of the Royal Horticultural Society.

Mr. Harvey spoke in high terms of the Manchester Botanic Society's

Exhibition, which he said had become famed throughout the world. Anyone having heard his remarks about the Liverpool Horticultural Association, and did not know anything about it, might have concluded that the Society was a feeble one. It is impossible for any Association to meet with the good wishes of everyone, but those who have visited the leading provincial shows during the past few years are fully aware that the one held in Sefton Park will compare favourably with any of them, while the spring and autumn meetings are second to none. In seven years, amidst considerable drawbacks, the Association has made for itself a name and taken a foremost place amongst the horticultural societies of this country. I venture to predict that by the continued support that has been so liberally accorded it in the past, that the operations of the Society will be widely extended with beneficial results to horticulture. The Society already possesses a subscription list of nearly £600, and nearly 20,000 people visited the three exhibitions of 1884. There was a slight falling off last year, owing to circumstances over which the Society had no control, but some of these were partly foreseen and therefore did not prove very disappointing. The Horticultural Association may not be worthy of a splendid city like Liverpool, but from year to year the Committee of Management have striven to attain this end, which can only be accomplished by time, patience, hard work, and the loyal co-operation of all who are interested in the progress of horticulture in the district.—A MEMBER.

### TRICHOGLOTTIS COCHLEARIS.

TRICHOGLOTTIS is a small genus botanically related to *Sarcochilus*, comprising about half a dozen species, one of the best known of which is

Fig. 34.—*Trichoglottis cochlearis*.

*T. fasciata*, but even this is seldom seen in gardens. *T. cochlearis* (fig. 34) is one of Messrs. J. Veitch & Sons' introductions, and a pretty addition to small-growing Orchids, and though scarce at present it will soon become a favourite as the stock increases and it is better known. The plant is dwarf in habit, scarcely exceeding 8 inches high as seen at present, and that shown in the woodcut was not more than 6 inches high, with thick slightly channelled leaves arranged in Vanda-like manner on opposite sides of the stem. The flowers are borne three or four together in small racemes springing from the axils of the upper leaves, and are remarkably pretty. The sepals are lanceolate; the petals are broader and rounder at the upper part, both being pure white barred with bright purple—a charming contrast. The lip is curiously hollowed or scoop-like, terminating beneath in a short conical spur, and the form being somewhat suggestive of a shell has given rise to the specific name adopted.

*Trichoglottis cochlearis* is a native of Sumatra, whence it was introduced to Chelsea a few years ago. It flowered in 1883, and was then

named by Professor Reichenbach, who considered it a distinct species. Our figure, we believe, is the first that has been given of this attractive little Orchid.

### MUSCAT OF ALEXANDRIA AND BOWOOD MUSCAT.

I WITH pleasure give your correspondent, "A Reader," particulars respecting the fertilising of these two Grapes. Bowood Muscat was in flower at the same time as the Madresfield Court, so they were fertilised together, using a soft plume of Pampas Grass at midday for six days. This was just at the time the boiler gave way. The Muscat of Alexandria was fertilised with pollen from Mrs. Pince. In previous years I used no other means than shaking the rods, and always had a better set on the Bowood than on the Alexandria.

I must also state that owing to a stoppage in the main pipe, through the pipes leading from the main being fixed wrongly (with a dip instead of a rise) the low places were full of sediment, so that for some time before the boiler gave way we could scarcely keep the water in the pipes in the Muscat house milkwarm. We knew the disadvantage under which the boiler was working, and had made arrangement for the relaying of the pipes as soon as we could do without fire heat. The reason I referred to the two sorts being shown together is that I fail to see the difference in the shape of the berries, as described in the Journal a few weeks ago, and the two as grown here would, I feel sure, be disqualified if staged as distinct sorts. I have been tempted to stage them as such, but having heard so many disputes about the two varieties in question I have really been afraid to do so. I shall be very pleased to let "A Reader" have a few eyes next autumn, and if he will grow them under the same treatment as the Muscat of Alexandria I think he will then agree with me in saying that this so-called Bowood Muscat is earlier, a better setter, and more robust in habit of growth. I may add, that of thirteen varieties of Vines grown here, Bowood Muscat produces bunches as freely as any of them, while only four set better.—G. G.

### ROSE SHOW FIXTURES, 1886.

BAGSHOT Rose Society, at Bagshot, Tuesday, June 29th.  
Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.  
Canterbury and Kent Rose Society, at Canterbury, Thursday, July 1st.  
Reigate Rose Association, at Reigate, Thursday, July 1st.  
Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.  
National Rose Society, at South Kensington, Tuesday, July 6th.  
Cardiff Rose Society, at Cardiff, Wednesday, July 7th.  
Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.  
Hitchin Rose Society, at Hitchin, Thursday, July 8th.  
Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.  
Cray Valley and Sidcup Horticultural Society, at Sidcup, Saturday, July 10th.  
Wirral Rose Society, at Birkenhead, Saturday, July 10th.  
East Gloucestershire Rose Society, at Moreton-in-Marsh, Tuesday, July 13th.  
National Rose Society, at Birmingham, Thursday, July 15th.—  
EDWD. MAWLEY, *Rosebank, Berkhamsted*.

### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 168.)

#### SPECIMEN PLANTS.

CHRYSANTHEMUMS grown in specimen form find many admirers, and exhibitions would lose much of their attractiveness if well-grown and skilfully trained plants were absent, despite what has been said against them. They are not useful for cutting purposes, as a partial loss of the blooms spoils their appearance, but where they can be conveniently arranged they have an imposing effect. There are two methods of producing specimens; one is growing them to a large size, say 5 feet in diameter, with 200 blooms on each plant: the other is limiting the plants to about 3 feet in diameter, with from thirty to fifty blooms of high-class merit, quality being the first consideration. Plants of this type are much more desirable than those grown for mere size, as the quality of the flowers must then be a secondary consideration, and plants unduly "stretched out" are gaunt and unsatisfactory. Medium-sized and not over-trained plants, remarkable for large deep green foliage and grand blooms, are the most meritorious, and are certainly the best for general decorative purposes.

For producing large specimens cuttings should be taken the first week in December, striking them in the way previously recommended. Take them from the handlights as soon as possible, and arrange them on a shelf close to the glass to keep them sturdy. By the middle of January they will be about 4 inches high, according to the variety, some sorts growing taller and quicker than others. At this stage they should be topped, just taking off the point of each plant. This induces the production of side shoots, which form the basis of the future specimen. As soon as the pots are fairly filled with roots shift the plants into 4½-inch

pots, using soil as previously described, returning them to their former position on the shelf near the glass in a cool house. As soon as the roots reach the sides of the pots place the plants on ashes close to the glass in a cold frame or pit, and protect them from frost, keeping them rather close for a few days. When the weather is favourable ventilate freely, and on fine days remove the lights. Before the plants become root-bound shift them into 6½-inch pots. As soon as the shoots have grown 5 inches long top them again. About the middle of May they should be placed out of doors in an open position safe from strong winds, but where they will have the full benefit of the sun and where they can be covered with some light material in the event of a frost occurring.

About the first week in June the plants will require their final shift into 12-inch pots, and about the middle of this month they must have their final topping. Plunge the pots half their depth in ashes. This prevents the soil drying quickly and keeps the plants firm, as if not secured in some way they are liable to be blown over in exposed positions. Attend carefully to watering, never allowing them to become dry at the roots, or the foliage will not be retained in that fresh healthy condition which is absolutely necessary in well-grown specimens. Syringe the plants in the afternoon or evening after bright days for refreshing them and keeping the foliage clean. If green fly attacks the points of the shoots dust with tobacco powder, and if mildew appears dust with sulphur. Place a stake to each shoot, which prevents their being broken off by wind or accidents. By this time they will be growing freely, and towards the end of July will have a large number of branches, some of them 2 feet long. At this stage they must be got into position. Commence by tying the branches out, having in view the size required, depressing them as may be desirable. Manipulated at this stage the branches bend more easily than they do later in the year, righting themselves much better, and when the plants are in flower bent stems are not so apparent, as training is done at a later stage. Bending the branches induces them to break into growth more freely. The plants make a natural break, forming a flower bud, about the middle of August. The branches produced from this break will each show a flower bud about the middle of September. These are the buds which should be retained for the production of the flowers. As soon as they are large enough to handle all other buds must be removed, retaining only the centre one. When the buds are swelling the plants must have their final tying. Thin stakes painted a colour which most resembles the branches and leaves are the best, as they should not be obtrusive. Secure the branches carefully to the stakes, leaving space for the stems to swell, as they thicken considerably at this stage. When in bloom the plants should be from 2 feet 6 inches to 3 feet high, pot included, the centre of the plant slightly rounded.

The plants should be housed according to the variety, be it late or early. Seven weeks for the late varieties, and a month or five weeks for others, will suffice previous to the time for flowering. Place the plants as close to the glass as possible, giving abundance of air and sufficient fire heat to dispel damp in wet or foggy weather. Feeding Chrysanthemums will be treated in a special article.

To grow specimens of the type represented in the engraving (fig. 35) the cuttings should be struck at the same time as the others, and the plants treated the same except in a few details. The pots need not be quite so large for flowering them in, 11-inch pots being ample size. The plants should be topped three times, the last time about the middle of June. The branches should be tied down a little earlier than for the dwarfed and larger plants, and it is important that the lower parts of the stems be bent, securing them to notched sticks, which can be pressed down from time to time for regulating the height of the branches. Bending and twisting the upper parts of the stems is a great mistake. Not a sign of this should be visible, but each branch should appear to come straight from the centre of the plant in a natural manner, and support a handsome bloom good enough to be arranged in a stand of cut flowers. Many branches are not required when the plants are grown under this system; therefore, at the natural breaking of the plant in August the shoots should be disbudded to the number required, thus causing those retained to be of superior quality, with robust foliage and eventually supporting grand blooms. Feeding and housing the plants should be carried out in the same way as the others.

The engraving is from a photograph of a small yet admirably finished plant grown by Mr. Hall of Brixton.

#### BUSH AND DECORATIVE PLANTS.

Where quantities of flowers are required for cutting, the bush method of cultivation is recommended, especially to amateurs, as a good show of blooms can be had in a small space. The plants not being tall are also well adapted for greenhouses or arranging in

certain positions in larger conservatories. Flowers can be had later in the season by growing two batches of plants. From the middle of January to the same time in February is the best time to strike the cuttings. When the plants are 4 inches high top them for the production of side branches, shifting as required before they are at all root-bound into larger pots, and keeping them stocky in growth; 8-inch and 10-inch pots are large enough to bloom them in, using the largest pots for the strongest growing. One topping is enough for some of the plants, while those required to be grown larger should be topped again when the shoots are 5 inches long. If a later batch of plants is required strike more cuttings in March. When the plants are placed out of doors do not allow them to touch each other, as the more air and space each one has the dwarfed it will be. Great care must be exercised in watering the plants, as much depends upon the quality of the foliage in a decorative point of view.

For the smallest plants three or four branches are sufficient to retain from the first topping, but in the larger size about eight is a fair number and sufficient to produce large bushes. If three shoots are produced from the first topping a dozen will spring from the

Fig. 35.—Specimen Bush Chrysanthemum.

second. Select from these the number required, and tie them securely to stakes. At the natural break of the plants in August many more shoots will be produced; these must be disbudded to the requisite number—about twenty-four on the large, half that number on the smaller plants, and from these numerous side shoots will grow and bloom. In September the flower buds will appear. If a few larger blooms are required take off all the buds except the centre one on each branch, but where a mass of flowers is preferred there should be no disbudding, and the stems will be clothed with flowers in abundance. After the central flowers are cut others are produced by the side shoots in succession. The plants should be housed in batches, allowing some to remain outside till severe frost compels their removal. Plants grown under this method require free ventilation, but not so much fire heat to prevent the flowers damping as those grown to produce large blooms. Place a stake to each main stem, or one strong stake in the centre of the plant, to which the branches can be tied loosely. Where the varieties are naturally of dwarf habit this answers very well; but in the case of taller kinds one stake to each branch makes all secure. Nearly all varieties of Pompons and Anemone Pompons are well adapted to this method of growth on account of their floriferousness.—E. MOLYNEUX.

#### EARLY TURNIPS.

No time should be lost in making sowings of Extra Early Milan and Early Snowball Turnips in drills 1 foot apart and about 1 inch deep in light soil in a rather dry and warm situation. If clean crisp roots are

wanted do not manure the ground further than giving it a good surface dressing of dry soot prior to sowing the seed and after the ground has been dug and sown. Afterwards rake the soot into the ground before drawing the drills, which should be closed in with the feet after the seed is sown, trodden and raked over so as to present a firm even surface. Early Snowball will make a good succession to Extra Early Milan, which is the best early Turnip in cultivation. After this, late sowings of Early Snowball in proportion to the demand should be made every three weeks up to the end of July, and early in August a good sowing of Orange Jelly, or some other good late variety should be made for winter use. Protect each sowing from the ravages of birds by a piece of garden netting supported by forked sticks, and as soon as the plants are large enough to handle thin them out at 3 or 4 inches apart in the rows; then draw every alternate plant when they have all started well into growth, so as to insure a good even crop. Run a Dutch hoe between the rows, as much with a view to accelerate growth in the plants as to destroy weeds.—H. W. W.

## NOTES FROM MY GARDEN IN 1885.—No. 1. GLADIOLUS.

THE whirligig of time has brought round again the season when I have been accustomed to give the results of my experience in my small garden for the past year; and for so doing I ought perhaps to draw up what used to be called an apology, for the area of my garden is so small that many people would wonder how I could possibly dare to say so much upon so small a basis. My chief answer to any who would find fault with me for so doing is that I am continually assured that these notes are of use to others who are similarly situated, who have not large means, and who desire to get as much enjoyment as they can out of their small surroundings, while their recurrence year after year is not so much a repetition as some might imagine it would be. Our seasons are so variable. The character of one year is so different from that of another that even the same things present a different aspect, and their culture reveals some new feature.

The two seasons of 1884 and 1885 will long be remembered for their prolonged drought, and the difficulties gardeners had to master owing to it. Few who have not looked into it know how very dry the soil had in many places become, for one season following on another had taken all moisture out of the soil. In light soils more especially had this been the case, while the heavy clay soils cracked so under its influence that it was almost as bad. Hence gardening presented many difficulties. Watering became so absolutely necessary as to absorb a good deal of time, while the hapless condition to which annuals were reduced was very pitiable. Moreover, the greatest amount of watering in no way compensates for the lack of rain. Fortunately here we have no lack of water, but in some places near us it was a very great difficulty. Springs failed, and there was the greatest difficulty in getting water for ordinary uses, so the poor gardens had to suffer.

Among those flowers which did not seem to suffer, but rather rejoiced in the drought, were Gladioli, and following out the plan which I had adopted last year—namely, that of planting them in the part of the garden where the soil was stiffest, I reaped the advantage in the past dry summer. The evidence which I have from many quarters leads me more strongly to the conclusion that a good stiff loamy soil (not clayey), with a good subsoil, and where the water does not remain about the roots, is that in which they most delight. I did not depart from my usual plan of planting, simply drawing drills about 4 inches deep, placing a little sand in the place where the corms were to go, and pressing them down firmly at the time of planting. My beds were all planted by the middle of March, the beds being in a very friable condition. This is a great point with them as with all corms. Where growers are exhibitors the time of planting is a matter of some importance. Where exhibitions are held in the early part of August I do not think that the first week in March is a bit too early for them. The dependance must be most placed on the flowers which bloom early. There are some varieties which will never bloom so early as that, but there are frequently amongst some of the later-blooming varieties a few of which for some reason or other throw up their spikes much earlier than their normal time.

I adopted rather extensively last season the plan of cutting the bulbs in halves before planting, and I am quite sure this may be safely done even with medium-sized corms with great advantage. Of course care is needed that when the skin is peeled off that the corm should not be cut unless two eyes are visible. By this means the number of plants is at once doubled, and my experience of this year goes to confirm the fact that some of the best blooms I had were from bulbs so treated, and that some of the largest roots that I lifted in the autumn were from these cut corms. With regard to the time of lifting there are differences of opinion. My friend Mr. Burrell of the How Nurseries, Cambridge, a careful and successful grower, leaves his roots in the ground to a much later period than I have thought advisable, not taking them up until December.

I took mine up in October, deferring it to later in the month than I usually do. As that happened to be a very wet month the difficulty of drying them was somewhat increased, and in some instances roots had been emitted from the new corm. As this must weaken it, I think that the leaving of them so long is a somewhat doubtful proceeding.

A good deal has been said in favour of Lemoine's new hardy hybrids of *G. purpureo-auratus*, but I cannot say that I am enamoured with them; in fact the more I see of them the less I care for them. But then I look at them with perhaps too much of a florist's eye; but certainly neither in point of colour, size of flower, or length of spike are they to be compared with the hybrid varieties of *gandavensis*. I again left some of these latter in the ground all the winter, but I shall never do so again. I do not think that the frost injures them so much as the wet, while worms of various sorts are injurious to them. There may be some soils and situations where they will answer, but certainly my garden is not one of them. I shall leave those which I have in their place, but shall not add to their number. The opinion that I have formed of them is shared in, I find, by most florists, while as subjects for a mixed border they may be considered suitable.

With regard to the newer varieties, I had several from various sources—Messrs. Soulliard & Brunelet, Mr. Kelway, and some from Mr. Dobree, and the following notes on them may be useful for intending purchasers.

### MESSRS. SOULLIARD & BRUNELET.

*Amitié*.—Plant tall and vigorous. Spike long and close. Flower fleshy rose colour, shaded with straw colour and lined with purple; the edges of the petals are flamed with a deeper shade of rose.

*Daphnis*.—Spike long and compact. Flowers large and well formed: beautiful salmon rose colour, flamed with slaty-violet, with white centre. Very distinct variety, and likely, I think, to be a favourite.

*Ganymède*.—This is a variety which may be pleasing to some, and is distinct, but is not of a colour for which I care particularly—a slaty amaranth; it has, moreover, a peculiarity for which I do not care—viz., having the edges of the petals fringed.

*Gordon Pasha*.—A long and well-formed spike; medium early in flowering; colour a rosy carmine, spotted with bright carmine, having also white lines on the petals. This a very distinct and pretty variety.

*Eugène Souchet*.—A fine spike of well-formed flowers of a beautiful bright rose colour, with large white spots and white lines on each of the petals.

*Stanley*.—A long spike. Flowers well-shaped, large, and open; colour a bright rosy salmon, flamed with a deeper shade of rose; with a rosy yellow spot passing into the ground colour.

There were some others, such as *Ali*, *Medeus*, and *Therese de Vilmorin*, which I did not grow.

### MESSRS. KELWAY & SON.

*Lady Carrington*.—Pale lilac, streaked with carmine, and a white centre. Spike good. Flowers large.

*Marquis of Hartington*.—Purple amaranth, flaked with lilac. Spike good.

*Mr. Struttinger*.—Flesh veined carmine. A pretty variety, with good spike.

*Rev. H. H. D'Ombraïn*.—"Self praise is no praise," they say, but I think that this is one of the best varieties Mr. Kelway has raised. I exhibited a spike of it at Dover, which was perfect, the flowers large and well open; the colour a beautiful cerise, with white throat. Of great substance and perfect shape.

*Calliphon*.—Rose, streaked with a brighter shade of the same colour. Good in shape and substance.

*Mrs. D'Ombraïn*.—White, when shaded quite pure; when unshaded having some lilac markings. A very beautiful flower.

*Admiral Willis*.—Red flaked and shaded crimson, having a large violet carmine spot. Very well shaped, with a good spike.

### MR. DOBREE.

These have been put into commerce by that well-known grower Mr. Campbell of Gourcock, whose stands of flowers at the Crystal Palace and South Kensington were so much admired, and who has a very high opinion of some of them.

*F. Bonany Hankey*.—Long spike of bright carmine flowers, with white centre. A very vigorous and hardy variety, and likely to be very useful.

*Herby*.—Long spike of handsome rosy carmine flowers; all the petals lined with white; centre very bright.

*Maggie*.—A very fine and striking flower; white, tinged at the edges with purplish carmine. A fine flower.

*Jane Mary Dobree*.—Fine spike of large well-shaped flowers salmon rose in colour. Flowers of good substance. A very pretty flower.

*Miss H. Pulman.*—White, when shaded pure, but at other times tinged at the edges with purple; narrow purple stripe in the centre of petal.

*Soldier of Bath*—Bright red; centre bright, and streaked with yellow. A showy variety.

I have so often stated what I consider to be the pick of the French varieties that I do not think it necessary to go over the same ground; but I may say that amongst those kinds which I consider to have grown in my good opinion are the following:—Mabel, Tamerlane, Dalila, Léandre, Mademoiselle Marie Verdale, Grande Rouge, and De Lesseps. As the time is now approaching when planting will have to be commenced no time should be lost by those who wish to add to their stock. It would be a good thing if we could see the number of those amateurs who grow this beautiful flower increasing, but I am sorry to say, as far as the south of England is concerned, there does not seem much prospect of it, the principal exhibitors at the Crystal Palace having hailed from the north. I can quite understand why it is. It is a very disappointing class of plants to grow, but it is none the less a great loss to admirers of the flower not to see more of them entered for competition; not indeed that there is much encouragement given to them about London, a paltry prize for twelve being all that the Crystal Palace Co. deems them worthy of, and there is no other place where they can be exhibited for competition. For the encouragement of growers I may say that after thirty years' growth of them I never have exhibited in such good form as I did during the past season.—D., Deal.

### BRUSSELS SPROUTS.

I QUITE agree with "A. L. G." as to the high quality and cropping of Aigburth. "S. B." says it is pretty generally discarded for better and more profitable varieties. I grew last year Aigburth, Daniel's Colossal, and Webb's Matchless, and found all good, but Aigburth produced nearly twice as much in weight and measure as the other two. I note also he states that Reading Exhibition or Gilbert's Universal are far better. I saw some Reading Exhibition well grown at Langford Park, and Mr. Stewart thinks very highly of it. The stems were tall and well cropped, and I quite admit it to be first-rate, but Gilbert's Universal I have never seen nor heard of, and certainly Mr. Gilbert is very quiet about his introduction. If "S. B." alludes to Universal Savoy, I can only ask him why a Brussels Sprout should be pretty generally discarded in favour of a certain Savoy.

"Lathyrus" is quite right in my opinion. A few novelties added to the seed list will always repay the small extra expense, and now and again you get a sterling gem which you would be without for a year or two if you waited till there was a general chorus of approval of it.—H. S. EASTY.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 9TH.

THE first promenade Show of the season was favoured with a bright sunny day, but the wind was so extremely cold that it deterred many intending exhibitors and visitors from attending. Though the display was not an extensive one, it was better than could have been expected, and the groups of hardy flowers formed a most interesting feature. Daffodils were in strong force, but were either obtained from warm early districts like the Scilly Isles, or had been forced under glass. They were, however, very welcome, and the collections of admirably grown Cyclamens constituted an important addition to the Show. The Orchids, which are now becoming so frequent at the meetings, were interesting and beautiful, several rare and well-grown specimens being included in the collections from amateurs and nurserymen, Mr. Smee's remarkable *Cyrtopodium Saintlegerianum* and Messrs. Laing's *Cattleya Lawrenciana* coming in for a large share of attention.

**FRUIT COMMITTEE.**—Present—Dr. Robert Hogg, in the chair; and Messrs. H. J. Veitch, Wm. Denning, G. Norman, W. Warren, John Woodbridge, F. Rutland, J. Ellam, Chas. Silverlock, G. Goldsmith, Phillip Crowley, T. Saltmarsh, G. T. Miles, T. B. Heywood, Harrison Weir, and R. D. Blackmore.

Mr. H. Mitchell, The Gardens, Aberaman Park, Aberdare, South Wales, showed a fine fruit of Pine Apple Black Prince, a fine conical fruit nearly a foot high, exclusive of the crown, for which a cultural commendation was awarded. Messrs. James Carter & Co., High Holborn, were awarded a vote of thanks for a collection of vegetables artificially preserved by a process patented by this firm. They comprised examples of the following:—Apples, Potatoes, Peas, Radishes, Beans, Mangoes, Tomatoes, Onions, Leeks, Capsicums, and Seakale. They appeared to have been coated with wax or something similar, and coloured. They were shown under glass cases, and attracted some attention. Mr. A. Miller, The Gardens, Rood Ashton Park, Wilts, sent an Apple called Rood Ashton Seedling, a flat yellow fruit, rather light, which was passed. It is described by Mr. Miller as "a first-rate culinary variety, an abundant bearer, keeping in good condition until April."

**FLORAL COMMITTEE.**—Present—G. F. Wilson, Esq., in the chair, and Messrs. John Laing, W. Bealby, Amos Perry, G. Duffield, James Walker, H. Herbst, Richard Dean, H. Ballantine, John Dornay, H. M. Pollett, E. Hill, James Douglas, William Holmes, G. Paul, A. T. Lendy, Harry Turner, Henry Cannell, Thomas Baines, and H. Bennett.

A very interesting group of Daffodils and hardy flowers was shown by Messrs. Barr & Son, King Street, Covent Garden, a large number of varieties being included, but a very good representative collection was staged. Some

of the most notable were Achilles, obvallaris, pallidus, præcox, princeps, Ajax, and albicans of the large trumpet forms, Telamonius plenus as a double variety. Of the medium crowned type there were Leeds Glow, incomparabilis sulphureus, Leeds superbis, incomparabilis Edward Hart, and others; with the double incomparabilis, Butter and Eggs and Codlings and Cream. The Poeticus section was represented by ornatus chiefly; and the Hoop Petticoat by Narcissus Corbularia conspicua, together with numbers of the Tazetta type. The Scilly Daffodils were from Tresco Abbey, the residence of T. A. Dorrien, Esq., and comprised some pretty varieties of cernuus, the Ajax group, incomparabilis, the diminutive minor and nanus. The Tazettas were very beautiful; Bazelman, white, gold cup; Gloriosa, white, orange cup; Aigle d'Or, pale yellow, gold cup; Jaune suprême, pale yellow, orange cup; White Pearl, white, lemon cup; Scilly White, white, cream cup; Grand Soliel d'Or, bright yellow, orange cup; Orientalis, white, gold cup; British Queen, cream, gold cup; Papyraceus, pure white; Imperator, clear yellow, gold cup. All these were very beautiful, and the collection altogether was most interesting. Other flowers in Messrs. Barr's group were Anemone fulgens very bright scarlet; Iris reticulata; Allium neapolitanum, pure white; Lachenalia pendula, deep red flowers, very large and drooping, tipped with green; Chionodoxa Lucilii, Freesia Leichtlini and refracta alba. A silver Banksian medal was awarded to Messrs. Barr & Son, and a bronze Banksian to Mr. Dorrien.

Mr. T. S. Ware, Tottenham, had an extensive and beautiful collection of Daffodils in pots, shown with their foliage and having a much better appearance than when the flowers are in glasses or bottles alone. A number of the leading varieties were represented similar to those already enumerated, and in addition there were notable specimens of Erythronium Dens-Canis purpureum, Cyclamen Coum album, Galanthus Elwesii, Narcissus Bulbocodium citrinus, N. monophyllus, pure white, with grass-like foliage, a charming little plant, and Crocus Aucheri, bright golden, very dwarf, and showy. A silver Banksian medal was awarded for the group. Messrs. Collins Bros. & Gabriel, 30, Waterloo Road, S.E., were awarded a bronze Banksian medal for a charming group of Daffodils representing all the sections, the flowers large, clear in colour, and very fresh. They were arranged in glasses with a few Ferns and Palms.

Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, exhibited a plant of the celebrated *Dendrobium nobile nobiliss*, bearing about two dozen flowers and buds, the former large and richly coloured, the crimson tint running deep into the sepals and petals; a plant of *Dendrobium crassinode album*, with white sepals and petals and a yellow lip; and the fragrant *D. heterocarpum Ellaiannm*, a variety with a yellowish lip. *Celogyne cristata maxima*, a very handsome variety, was represented by a plant with a spike of six flowers, for which a cultural commendation was awarded. F. A. Philbrick, Esq., Q.C., Oldfield, Bickley (gardener, Mr. Heims) was awarded vote of thanks for a plant of *Lælia lilacina*, a supposed natural hybrid between *Cattleya* (*Lælia*) *crispa* and *Lælia Perrini*, collected and imported in 1883; it differs in the lip from *Lælia Pilcheri*, and is intermediate in the period of flowering between the two supposed parents. The sepals are pale blush, the lip white in the throat, tipped blush and streaked with crimson. The plant was very healthy and had ten flowers.

In addition to the *Cyrtopodium* certificated, Mr. Cummins had a fine variety of *Odontoglossum maculatum* with large flowers, the petals and lip very broad and of good colour. Mr. Clarke, Eversleigh, Herne Hill, was awarded a vote of thanks for *Dendrobium Devonianum*, bearing a growth forming quite a wreath of flowers. A cultural commendation was adjudged to Messrs. F. Sander & Co., St. Albans, for plants of *Celogyne cristata maxima*, a variety with extremely large flowers. Messrs. Thomson & Son, Clovenfords, showed flowers of *Dendrobium Lechianum*, the beautiful hybrid of the Ainsworthii type. Messrs. J. Laing & Co., Forest Hill, showed two plants of *Cattleya Lawrenciana*, bearing three flowers each, the sepals and petals pale purplish crimson, the lip extremely rich crimson, very beautiful and something of the C. Skinneri character. *C. Trianae Laingi* is a handsome variety with broad deep blush petals and an open crimson lip. A deeply coloured variety of *Dendrobium crassinode* was also sent by the same firm. C. L. N. Ingram, Esq., Elstead, Godalming, sent a variety of *C. Trianae* called Ingrami, the petals broad, nearly white, with an intense crimson lip, yellow in the throat.

Extensive groups of Cyclamens and Primulas were contributed by several firms. Mr. B. S. Williams, Upper Holloway, had a particularly fine collection of varied and highly coloured flowers. The St. George's Nursery Company, Hanwell, and H. Page & Son, Teddington, also had large groups, for each of which a silver Banksian medal was awarded. Messrs. J. Carter and Co. showed fourteen baskets of Primulas, representing their choicest strains of these popular plants, white, crimson, blue, mauve, rose, and purple; the flowers large and the colours bright. A vote of thanks was accorded. Messrs. H. Cannell & Son, Swanley, exhibited flowers of the pretty white *Begonia nitida alba*, the blush white *nitida*, and the deep red *gigantea rosea*, all useful winter flowering varieties. A plant of *Cyclameu giganteum*, improved, a variety with enormous flowers, was also shown. Mr. W. Bull, Chelsea, had a plant of *Cattleya Lawrenciana* in flower, and an elegant foliage plant, *Cupania grandidens*, with pinnate leaves, the pinnæ deeply sinuated. A vote of thanks was awarded for seven plants of *Lilium longiflorum floribundum*, with three to four pure white fragrant flowers each. A *Cineraria* was shown by F. Braby, Esq., Bushy Lodge, Teddington (gardener, Mr. Clinkaberry), with flowers of two distinct colours on the same plant, some being rosy crimson and the others rich purple. Mr. J. James, Woodside, Farnham Royal, had a box of richly coloured *Cineraria* flowers, large and handsome, as the blooms of his well-known strain always are. G. F. Wilson, Esq., F.R.S., Weybridge, was awarded a vote of thanks for a potful of *Galanthus Imperati* with large flowers. Mr. F. Crute, Waltham Abbey, Wood Green, sent samples of his concave flower-pot and cup. Mr. A. Smith, Reading, had specimens of ornamental tiles for window-boxes, and Messrs. Foster and Pearson, Beeston, Notts, showed a patent metal ventilator with a hinged door, to remain open or shut.

### CERTIFICATED PLANTS.

*Cyrtopodium Saintlegerianum* (G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington).—A wonderfully strong species from Paraguay with cylindrical tapering pseudo-bulbs 2 feet to 3 feet long, with stout panicles rising from the base 4 to 5 feet long. The flowers are about 2 inches across, the sepals yellow, barred and spotted with reddish brown; the petals

slightly broader, yellow, with a few spots at the base; the lip is similar with two wings curving round the column of a reddish tinge, and the pedicels are also reddish, but those and the main peduncles being subtended by lanceolate bracts, greenish, with reddish bars and streaks.

*Narcissus Bulbocodium citrinus* (Ware).—A charming variety of the Hoop Petticoat Narcissus; the cup  $1\frac{1}{2}$  inch in diameter and  $2\frac{1}{2}$  inches long, of a delicate pale yellow tint.

*Begonia gigantea rosea* (H. Cannell & Sons).—One of the semperflorens type, with large leaves and dense panicles of bright coral red flowers very rich in the bud state.

SCIENTIFIC COMMITTEE.—F. Du Cane Godman, Esq., in the chair.

*Colletia horrida (speciosa)* on *C. bictonensis*.—Dr. Lowe exhibited specimens of a shrub of *C. Bictonensis* with dimorphic branches, the smaller kind growing on the larger, differed from *C. horrida* in having the branches flattened and not rounded, as in the latter. This was also the case of the specimen exhibited at the last meeting; and Dr. Lowe raised the question whether the growth of this small form of *C. bictonensis* had not been mistaken for *C. horrida*. It is requested of persons cultivating this plant to examine them and report to the Secretary as to the frequency of the true *C. horrida* growing upon flattened *C. bictonensis*; also, if *C. bictonensis* with broad flat branches is ever known to grow upon a shrub of *C. horrida* with round branches. Specimens will be very acceptable. He alluded to an ancient Italian painting of "the Crown of Thorns" having this sport depicted in it.

*Melanthus major*.—Dr. Lowe showed a plant completely killed by the late frost, but which was in blossom at the same period of the year of 1885.

*Nematoid Worms in Cucumbers*.—Mr. Michael gave a very interesting communication upon the great injury occurring to Cucumber plants in Cornwall. In a collection grown largely for the London market plants were continually being struck down. A careful examination of the earth proved that the source of the mischief was entirely due to these worms. On examining the sound parts of the roots where the disease was just commencing, he discovered cysts of eggs deposited in those parts, the female having burrowed more deeply into such tissues to provide food for the young ones. Mr. Murray said that he had made similar observations in conjunction with Mr. Carruthers, and they had come to precisely the same conclusion. Other animals, such as acari (*Serraton rostratus*), as well as *Rhizobryophus*, were present; but these were not the cause of injury, but only followed on the decayed condition induced by the nematoid worms. He suggested sulphur and lime should be applied round the roots, and that all affected plants should be burnt.

*Orchids, monstrous*.—Mr. O'Brien showed a specimen of *Ojontoglossum crispum*, and Mr. Smee brought a blossom of *Cologyne cristata*; the latter was a fusion of two flowers, but one was represented solely by a labellum and a bract. They were referred to Mr. Ridley for further examination.

*Camellias and Frost*.—Mr. O'Brien, commenting on the leaves sent by Hon. and Rev. Mr. Bo-cawen to the last meeting, remarked that he had observed exactly the same result to accrue from scorching by the sun; that the young mature leaves resist it much better than the old mature leaves, though if immature they suffer to a proportionately greater degree.

*Cineraria Dimorphic*.—Mr. F. Braby of Bushey Lodge, Teddington, sent a plant having half the flowers crimson and the other half deep mauve; it was a seedling. Mr. Lynch exhibited blossoms showing somewhat different character in the central and terminal flowers to the lateral ones, not only in being larger, but with a different disposition of the ray petals.

*Abutilon igneum*.—Mr. Lynch exhibited sprays of the South American species with dark purplish flowers.

#### GLASS COVERS FOR WALLS.

MANY country houses are fitted with double glass window frames for winter protection, and none situated in the north of England and Scotland ought to be without them. The past few days of storm (1st to 3rd March) give proof of this. The wind howl, and the snow-drifts are deep, but inside the double glass the sough of the wind in the trees is scarcely heard, and the fire does not run up the chimney. Your notice, with sketch, of the "Darlington" glass wall covers induces me to suggest the utilisation of these protective window house frames during summer in ripening Peaches, &c. Some years ago I put outside glass frames into the windows of my three public rooms—seven windows in all. The frames are entire (without break), and are caulked round with a soft packing so as to be tight.

From March to November these are placed in a light permanent frame, in front of and within 3 feet of a wall of Peach trees, and this with complete success. The window frames being entire, as stated, ventilation is obtained at the bottom bar, which (about 9 inches deep) admits of a slot with closing lid about 30 inches by 6 inches, which is sufficient for room ventilation in winter, and for the Peaches in summer with an additional arrangement below the bar upon which the glass frames are set. As these window frames require removal in summer at any rate, by this plan of stowing them away they yield me fine crops of Peaches of the early sorts. I find Early York will not do, but Small's Mignon and the Sulhamstead are charming.—EAST COAST SCOT.

#### BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

THE first lecture in connection with this Association was delivered on Wednesday evening, March 3rd, at the Society's rooms, Albert Chambers, Paradise Street, Birmingham, by A. W. Wills, Esq., F.C.S., one of the Vice-Presidents, the chair being occupied by Mr. W. B. Latham, Curator Botanical Gardens, Edgbaston, about 120 members being present. The Lecturer, who is an enthusiastic admirer of the various forms of Nature, after pointing out that the principal object of the Gardeners' Mutual Improvement Society should be to stimulate its members by intercourse and study to acquire a better knowledge of the wonders of creation into contact with which

they are brought by their daily work, proceeded to show what are the chief subjects comprised in the study of botany. He pointed out that this may be made one of the most uninviting or one of the most fascinating of pursuits according to the manner in which it is approached, and as an illustration of one of its aspects which lift it into the region of poetry and romance, he chose the topic of "The Mutual Relations of Flowers and Insects," the object of the speaker being to prove how and why it is that but for the co-existence of insects and their services in the fertilisation of flowers the glory and the grace of the plant world would vanish from the face of the earth, and all the myriad forms of beauty which adorn the forests of the tropics and the moorlands, woods, and meadows of temperate regions would disappear, so that only a few tribes of plants, all bearing sombre and inconspicuous flowers, would survive, while all colours and scent and variety of form would cease to exist. In tracing this subject, Mr. Wills dealt first with the structure of a typical and perfect flower, and the functions of the parts concerned in reproduction, and then, after showing how the visits of insects are the chief agency for insuring fertilisation, proceeded to show how Nature encourages cross-fertilisation and discourages self-fertilisation by a variety of general arrangements, as well as by special contrivances. These latter reaching their climax in the structure of Orchids. The address concluded by a brief reference to the connection of this subject with that of natural selection. It was illustrated by a large number of illuminated transparencies, mostly drawn from nature by the Lecturer.

Mr. Latham, in moving a hearty vote of thanks to Mr. Wills for his very able and interesting address, said he thought that he had dealt with a subject of the greatest importance to the gardening profession, more particularly to its younger members, whom he advised to try and acquire a thorough knowledge of the parts and functions of flowers. The resolution was carried unanimously, after which the Chairman drew the attention of those present to the subject of the next lecture, to be delivered by Professor Hillhouse, on Wednesday evening, March 17th—namely, "The Scientific Value of Gardeners' Experience," which he had no doubt would be very interesting, and he hoped to see as good an attendance of members as on the present occasion. The meeting then terminated.

#### MUSHROOM-GROWING ON OUTSIDE BEDS.

We are well into the ninth week of frost, more or less. On Monday we were visited by a very severe snowstorm, and I may say without exaggeration that at present frost and snow reign here supreme, but it is well known that cooks have little sympathy with us. At the present time I have seven of these worthies to supply, and of course they want Mushrooms as often as they can get them. March 4th was the packing day, and we have been well supplied all through the winter from the Mushroom house, but to-day we could not get enough by 4 lbs. The sun being shining brightly, I determined to try the outside beds. The first and only bed we opened was a round one, and about the size of an ordinary haycock, and to my great delight we obtained the 4 lbs. of such Mushrooms, thick in the flesh and red in the gills, and doubtless superb in flavour. Does not this conclusively prove what Mr. Wright states in his book, that Mushrooms can be grown outside all the winter? The great secret to success in growing Mushrooms is always to use fresh spawn—namely, that which you can break with your finger and thumb. If a hammer has to be used to break the spawn the vitality has departed. This I have proved often.—R. GILBERT, *Burghley Gardens*.

#### HARDY FRUIT GARDEN.

**KEEPING FRUIT.**—Some complaints have been sent to us of the premature decay of fruit in a fruit room in which fruit has been kept—and kept well for many years. Such complaints after so favourable a season as the last was for the perfect development and ripening of fruit caused some surprise, and a little inquiry showed that neither fruit nor building were in fault, the mischief being clearly traceable to ignorance and carelessness on the part of the person in charge of the fruit. At this late period of the season the only advice that is likely to be useful, is to suffer no decaying fruit to remain among that which is sound, to avoid handling fruit more than is absolutely necessary for inspection, to keep out frost and dampness, and to have the place of storage sufficiently ventilated to prevent any internal accumulation of moisture.

Experience and sound judgment are required to enable one to decide when fruit should be gathered from the trees. There can be no doubt that much fruit is spoiled by being gathered too soon. The falling off the tree of two or three, or a dozen Apples or Pears, is not to be regarded as a sure sign that all the fruit is ready for gathering. To stroll into a garden and pull a fruit may read well in a popular novel, but there must be no pulling by fruit-growers, or we may have a wholesale destruction of spurs and spoil both trees and fruit. The best test is to lift or turn the fruit gently upward, and if then the stalk parts readily from the branch the fruit is ready for gathering. Carelessness in gathering and storing is too frequently the cause of premature decay. The fruit is thrown into baskets, out of which it is shot hastily into bins or upon shelves, much bruising is inevitable; bruised fruit soon becomes rotten, and then we are told that "fruit does not keep well this season," or that the fruit room is at fault.

Surely it is patent to everyone that fruit is easily bruised, and it requires no mighty intellect to see that bruising may be avoided by the exercise of due care.

For ordinary purposes a single fruit room is sufficient, but for large fruit gardens we would always have two rooms, one for Pears and the other for Apples, and there should be means provided for raising the temperature of the Pear room at will. In most gardens this might easily be done by a 4-inch flow and return pipe connected with the nearest boiler and controlled by a valve. Many of our mid-season and late sorts of Pears do not ripen well in a cold fruit room, but in the temperature of a sitting room they soon develop sweetness, richness, and aroma, and such a temperature is easily imparted to a Pear room.

#### FRUIT FORCING.

**VINES.—Early-forced House.**—Early Grapes that have passed the stoning process will be greatly benefited by having liberal supplies of tepid liquid manure given to the inside borders. Great advantage also results from syringing the paths, walls, and mulching over the roots with clear liquid manure towards evening on fine days, or an hour or two before night ventilation is given before dark. After the stoning is completed a little ventilation at the top of the house will prevent the deposition of moisture on the berries during the night. The bunches should be examined for the last time, and if any small stoneless berries remain remove them at once, as nothing detracts more from a well finished bunch of Grapes than these imperfectly fertilised berries. Lateral growth should be encouraged all over the house by pinching the points out of the strongest only, tying those down to the trellis, allowing the weakest to find their way up to the glass, when they should be stopped and tied down so as to prevent the foliage touching the glass. Commence ventilating early, little and often through the early part of the day, and reduce upon a similar principle, and finally closing in time to run it up to 85° on bright afternoons.

**Succession Houses.**—Attend to disbudding, tying, and stopping in succession houses, keeping the thinning both of bunches and berries well in hand, commencing with free-setting varieties, but Muscats and other shy-setting sorts should be left until the best berries take the lead. Keep up a steady circulation of air where houses contain Grapes in bloom, impregnating shy setters when the maximum temperature is reached, taking pollen from Hamburgs for fertilising Muscats. Shy setters have the stigmas coated with glutinous matter when in flower, and rarely set well unless it be removed daily with a camel's-hair brush.

**Late Houses.**—Former instructions having been attended to, the Vines will now be moving. Ply the syringe freely several times a day, give the inside borders good waterings with warm liquid manure, and endeavour to secure an even break and elongation of the bunches by closing with a humid atmosphere at a temperature of 75°. Strong young canes that do not always break evenly should be kept in a horizontal position until all the lower buds have started, but old Vines on the spur system do not require this attention.

**Fruiting Vines in Pots.**—Keep these well supplied with good stimulating liquid, make additions to the top-dressing and mulching, and allow the laterals to spread over all the uncovered parts of the trellis; but nothing is gained by crowding the foliage. It should have full exposure to light and air.

**PINES.**—It is usual at the beginning of this month to start enough suckers for the prospective requirements, 5 and 7-inch pots, according to the size and variety, being used, and the suckers potted firmly in good loam in a moderately moist condition, and, without being watered, plunged at once in a fermenting bed previously prepared, having a temperature of about 95° at 9 inches beneath the surface. In ten days or a fortnight roots will be appearing at the sides of the pots, when water should be administered, and as often as occasion requires afterwards. Owing to the moisture arising from the fermenting material but little syringing will be required, but with increased light, heat, and sun, and growth in the plants, it will be required more liberally. The temperature should be maintained at 60° at night and 70° in the daytime, a slight shade being applied for an hour or two at midday when sun is powerful, closing in good time so as to make the most of the sun heat.

**Plants Wintered in Small Pots.**—Those that have been wintered in 7 or 8-inch pots should be shifted during this month into pots 10 or 12 inches in diameter, in which they produce fruit during next autumn and winter months. The rough part of fibrous loam only should be used, the pots being perfectly drained, scattering a small handful of wood ashes over the drainage to prevent the inroad of worms and a few half-inch bones, some of these being mixed with the turf in potting. In potting be careful to avoid having vacuous places, the compost being put in carefully and rammed down so as to form a compact mass with the ball. The plants after potting should be placed in a brisk heat about the pots of 90° to 95°, growth being encouraged under favourable external conditions in a temperature of 65° to 70° at night, and 75° to 80° during the day, with a rise of 5° to 10° from sun. Sunny weather should be taken advantage of in every department to close early under the sun's invigorating influence, being liberal in syringing or sprinkling lightly overhead all the plants excepting such as may be in flower at the time.

**STRAWBERRIES IN POTS.**—First dishes are much later than usual, the season not having been propitious for early produce. Keep constant supplies in readiness to take the place of forward crops. All the late varieties will be the better of being surface-dressed, and arranged in pits well up to the glass so as to prevent the foliage drawing, and in these with free ventilation they will develop strongly. Henceforward fine

fruits are expected, and to insure well-set evenly shaped berries fertilisation should be carefully performed in the middle of fine days. Remove all the upper flowers from the flower scapes, leaving from eight to a dozen of the finest formed fruit on a plant, and in the case of the large-growing kinds a further reduction may be made. A little artificial manure (of which there is now so many valuable preparations that for obvious reasons no one can especially be named) may be scattered over the surface of the pot and watered with a fine rose when the soil is in a fairly moist condition. Liquid manure from soot and cow manure made fresh is a capital invigorator. Be careful not to over-water, especially in dull weather, guarding equally against dryness, though a supply of water ought always to be needed before it is given, and then thoroughly. Assist plants swelling off their fruits by closing early so as to raise the temperature to 85° or 90°, and syringe overhead on bright days. Avoid giving a check to fruits developing towards maturity by lowering the temperature suddenly; but moisture should be gradually withheld with a view to insure flavour.

## THE BEE-KEEPER.

### MARKETING HONEY.

THE question is often asked, What is the most profitable form to produce honey for sale, comb honey or honey out of the comb?

The answer depends in each particular case on the market the seller wishes to supply. Some customers will only buy comb honey, others prefer run or extracted honey, and the adage holds true in this as in every other case, that we must cut our coat to suit our cloth, and that where there is a ready market for comb honey we must manage to produce, or, to speak more accurately, get our bees to produce honey in the most convenient form—sections. Honey may be divided into two classes, comb honey and liquid honey, and these again will be split up into two divisions, sections and super honey, extracted and run honey.

Within the last few years there has been a considerable fall in the price of all kinds of English honey, and in a former article we endeavoured to account for this, and so we shall take for granted the fact, that though in some places there has not been so great a fall in price as in others, still, however much disagreement there may be as to the causes, there can be none as to the effect.

In the report of the Lancashire and Cheshire Association for 1884, the statement is made that one member sold 8 cwts. of extracted honey at 10½d. per lb., and that another member sold 400 lbs. at 1s. 2d. to 1s. 6d. per lb., and Mr. Carr goes on to say that, "The idea of selling honey at the very low prices talked of in some quarters appears to only cause amusement among members as far as I could gather."

During last year several tons of English honey changed hands at £60 per ton, which is not quite 6½d. per lb., and some hundreds of 1 lb. sections were sold at prices ranging from 6s. to 9s. per dozen. Supers of honey fetched rather less, owing to the difficulty of breaking bulk, and the loss from waste, &c., while the old-fashioned run honey taken from skeps, and not extracted, was sold for about 5½d. per lb.; so that in discussing the question of marketable honey we may confine ourselves to section honey and extracted, and on the whole we should say that the latter is the more profitable to the bee-keeper, though there is perhaps less trouble in getting section honey.

If he can sell his sections as soon as they are filled, or at least has only to keep them for a short time, the bee-keeper will not have the trouble of extracting; but when sections become granulated there is a difficulty of disposing of them, and even if they are melted and the wax strained off, the honey is not as good in quality or appearance as if the honey had been extracted.

To keep sections from granulating is no easy task, as the temperature has to be kept up to about 70°, and even then a slight draught from an opened door will cause them to granulate in a few minutes.

If extracting is carefully managed there is no danger of robbing, either by the other bees in the apiary or by stranger bees. All combs should be extracted in a room or shed, so that the bees cannot get in. When we are extracting from frames we take out two or more frames, empty them by means of the extractor, and then go to hive No. 2, remove those frames that are full, and in their place put the frames belonging to hive No. 1, and when we have finished extracting the empty space in hive No. 1 is filled up by the frames we took out of the last hive. By this means the bees are least disturbed, and we have never had any robbing. In extracting sections we remove the full crate, and place an empty crate or cover with carpet. Having brushed off as many bees as we can, we take the full crate into a room or shed, brush off any remaining bees into an empty skep or box, and after extracting the sections replace them in the crate, and replace on the hive, and if we are careless enough to spill any of the honey swab it up with a wet cloth. The bees having the empty comb will soon fill it again if there is any honey coming in, and so we can use the same sections over and over again.

Fortunately the public are beginning to understand that granulation is more or less a proof of genuine honey, though there is now said to be a process by which even granulation can be imitated, and that a large quantity of spurious granulated honey is now being placed in the market.—A SURREY-SHIRE BEE-KEEPER.

#### BEE DIFFICULTIES—PREVENTING SWARMING.

I SHOULD be grateful for information and advice on all or any of the following points :—I have a bar-frame hive taking ten frames at right angles to the entrance. I put a swarm into this hive in June, 1883. The next season I put on a crate of twenty-one sections, but the bees refused to enter them, and a swarm issued. Last May (1885), the bees being very strong, I again tried the super, when they entered it and commenced working; but in about ten days a large swarm left the hive, followed twelve days later by a cast, both of which I put into straw skeps. The bees in the bar-frame hive are very strong and wintering on seven frames, a dummy taking the place of the three removed. What should I do during the coming season to prevent swarming and enable me to obtain the best yield of honey? I think of having another bar-frame hive this spring, and should like to know the best one to adopt and the mode of working, so as to obtain the greatest honey yield. Also, which do you consider is the best of the many smokers, honey extractors, and works on bees (cheap) now advertised so largely? Only having limited time and means for devoting to my bees, plain, practical, simple, and economic advice on these subjects will be greatly esteemed by—J. C.

[There are two reasons, either of which may account for the non-success following the efforts to get the stock to enter the super in 1883. If the swarm with which the bar-frame hive was stocked in 1883 was a first one, the queen, in all probability, was an old one, and perhaps so old as to be unable to keep the stock filled with brood, and this might have been a factor in causing the issue of the swarm in 1884. Again, if the sections were placed too late—even if the queen was young and in full vigour—preparations might already have been made for sending forth a swarm, and when this is the case a bee-keeper can only blame himself, and hope that, taught by experience, he may another year be more successful. To prevent swarming queens must be young and supers placed in the nick of time. In 1885, indeed, the first of the above-mentioned causes was absent, for the queen was evidently, judging from the antecedent history of the stock, young—scarcely a year old; but even then there was only partial success, and the reason of failure was this :—When bees were working freely in the crate of sections first given them another crate should have been added, either being placed above or below the former, and thus crate added to crate, room always being provided in advance of the requirements of the stock. As each crate is completed it should be removed and another added, until the judgment of the bee-master tells him that the season is drawing to a close, when all his efforts must be directed to getting the sections already partially filled completed; and even if at this time the bees are a little short of room there is not much—at such an advanced period—likelihood of a swarm issuing. In the cases above, however, not only a swarm, but a cast issued by reason of insufficient room being provided at the necessary time, but even then with judicious management a partial success might have been achieved. If when the cast came out it had been hived in the usual manner, placed on a temporary stand as near as possible to the stock from which it issued for four or five hours, and then thrown back on to the front of the parent stock, the cast would have quietly entered the hive, and in nine cases out of ten often remained working in supers until the end of the season. This is worth a trial, for there is little trouble attending the operation and no skill is required. Let a trial be made if a swarm and cast again issues, and it may be added if the cast should issue again the next day a similar method of procedure must be adopted with the certainty of final success. If a cast returned should issue again, it shows the intention of the stock to throw a second

cast, and this must in all cases be prevented. A second cast is certainly detrimental to the strongest of stocks and of little value to the bee-keeper.

Again, this year the bar-frame hive contains a young queen not one year old, the one straw into which the first swarm was hived a queen not more than eighteen months old at most, and the other straw into which the cast was hived a queen a little younger than that of the bar-frame hive, so that so far as young queens are conducive to success in the production of comb honey in opposition to increase, the circumstances are favourable. If, then, super honey is required, all the efforts of the bee-master must be exerted to prevent swarms, not by cutting out queen cells and other such means, but by preventing preparations being made for increase by a judicious supering management, as before explained. But let it always be remembered that one day's delay in placing a super when a stock requires extension may cause queen cells to be commenced, and if this is the case it is better either to take at once artificially, or to allow one to issue naturally, return the cast, manage the swarm so as to have it ready for supering, for which, if it comes out in good time, it will be ready long before the close of the honey flow, and thus have both stock and swarm at work in supers. For certainty, however, of getting super honey year by year in greatest quantity at the least expenditure of time and trouble, prevention of swarming is the most reliable system of management.

The requisites for a good bar hive are four :—1, Good workmanship. 2, Sound wood. 3, Capacity to contain sixteen standard frames at least. 4, Adaptability for filling 100 1-lb. sections. From hives of ten frames only great results can be obtained, and in my own apiary ninety 1 lb. sections have been taken from one such, but the larger size is preferable. Dark walls and frames at right angles to the entrance seem to be, as far as my experience goes, the best, but although it is well in making or purchasing a new hive to get a good one, it is not the hive but the owner's management which causes success or disaster. If less dependence was placed on hives and more on management, profits would be greater and expenses less. The Bingham Smoker is a good, but I am unable to say which extractor has the preference, but for one who desires "plain, practical, simple, and economic" advice there is apparently no necessity to invest in an extractor at all; but the point is one which "J. C." can well decide for himself. Of books none is more suitable for anyone desiring to get good sound practical knowledge than the "Handy Book of Bees," by the late A. Pettigrew; "Manual for the Many, Bee-keeping," by the late J. H. Payne; and from the books of the more advanced school I am quite unable to pick out the one likely to do least mischief.—FELIX.]

#### TOMTITS AND BEES.

I can fully endorse what "G. H. P." says relating to the blackcap tomtit destroying the honey bee. My father has kept bees for the last forty years, and during the winter they are very troublesome. It is a custom of his to reduce the entrance of the hive in the autumn with a piece of cork cut to fit the aperture, so that the bees can better defend themselves against the attack of wasps. The corks are in many cases pecked half away by the tomtits to disturb the bees, and as soon as one shows himself he is caught, and as "G. H. P." says, carried to the most convenient place. I have even seen the tomtit catch the bees when they have been at work at the Cherry blossom in the spring.

The best mode of catching the tomtit is with the small steel mouse trap fastened on a stock with a screw, the stake driven in the ground so that the trap is on a level with the alighting board.—W. L. B.

"G. H. P." (page 162) asks if other bee-keepers have found the tomtit destructive to bees. I have many times seen "Master Tommy" behaving himself precisely in the manner he describes, and have long looked upon him as an enemy to my bees. I do not know if swallows are generally considered to be destructive. I saw them last summer skimming among my hives when the bees were on the wing, and though I did not see the fatal snap I have a very strong suspicion that they were reducing the population of my stocks.—T. S.

#### TRADE CATALOGUES RECEIVED.

Waite, Nash & Co., 79, Southwark Street, London, S.E.—*Wholesale Catalogue of Agricultural Seeds, 1886.*  
Samuel Shepperson, Prospect House, Belper.—*List of Florists' Flowers.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (M. Spiering).**—We are not aware that an edition of "Paxton's Botanical Dictionary" has been published since the date you name. Probably the last edition of "Johnson's Gardener's Dictionary," published in 1832, and comprising all plants introduced into gardens up to that time, may suit you. It can be obtained at this office, price 7s. 6d., post free to Hanover for 8s. 3d.

**Glasses for Roses (Juvenis).**—We are not able to say where the "cheapest glasses" of the kind figured in an advertisement in the "Rosarian's Year Book" can be obtained. Possibly the advertiser might give you information, his main object, we presume, being to sell his Rose holders, and hence he shows their adaptability for the glasses in question for room adornment, as well as for tubes for exhibiting blooms.

**Soil from Violet Bed (J. T. S.).**—If the soil dried in the bed in summer into any such hard lumps as we received, Violets could not possibly thrive in it. Such heavy adhesive clayey loam could only be added with advantage to very light dark-coloured soil rich in humus, of which the sample you have sent is destitute. Neapolitan Violets will not grow freely in heavy soil that is greasy when wet, and bakes like bricks in dry weather.

**Charcoal (J. P.).**—Wood burned as you suggest can hardly be described as a "substitute for charcoal," for it will be genuine charcoal, and as good as you can obtain elsewhere for potting purposes. It is very useful indeed for mixing with soil for most kinds of plants, and none the worse for those of a softwooded nature if previously soaked in liquid manure and partly dried before using. It should be broken into small particles, mixing one handful with twenty of soil, and potting firmly. Larger particles are excellent for drainage.

**Rhodanthes in Pots (Old Subscriber).**—Some of the beautiful examples sold in the market are produced by sowing seed in 5-inch pots, thinning out the seedlings before they touch each other, so that those remaining are not more than an inch apart; others are raised by transplanting sturdy seedlings about the same distance asunder, growing them near the glass in warm light pits. Great care is requisite in watering, and it is not a good plan to sprinkle the foliage, especially early in the season.

**Layering Lapagerias (D.).**—The whole of the moderately firm portions of the shoots are pegged in the soil, about half the length of each leaf protruding above the surface, producing an appearance as if a number of leaves were inserted in the bed. This is done in early autumn, and young growths push in the spring. You can layer some now, and roots will be emitted in due time, whether the shoots are notched or not, in a bed of sandy peat kept regularly moist.

**Marechal Niel Rose Unhealthy (A Young Gardener).**—You appear to have injured the Rose by "steaming" the house, but why you steamed it to such an extent we are at a loss to know. Generally speaking, it is unwise to steam houses containing flowering plants, and especially at this season of the year. Time and judicious management may perhaps bring improvement. You say nothing about the age or size of the Rose, how it has been pruned, or whether it is in a pot or planted out; therefore we are not in a position to advise you how to proceed in its management.

**Calendarial Notes (R. Savill).**—Most assuredly our notes are specially written every week by expert cultivators in actual practice, and we do not adopt the method, which is not unknown, of dishing up old calendars. We have plenty of Peas above ground that have been dusted with soot, and we have sown Carrots and Radishes, also planted Potatoes, close to a wall facing south, where protection can be easily given, and we expect good crops in due time. No one, we presume, would either sow or plant with the ground covered with snow.

**Marechal Niel Rose (E. S.).**—If you wish to have all the blooms possible irrespective of the after condition of the plant you have purchased, only remove the miniature tips of the shoots, and as these are "strong and well ripened," most of the prominent buds will in all likelihood produce a bloom, and if the roots are active in good soil, and well supplied with water the flowers may expand; but in all probability the plant would be so exhausted as to be of little further use. The best plan to adopt for inciting growth after flowering would be to cut down the stems to the best wood buds you can find below the parts that have produced flowers. If the permanent well-being of the plant were the first consideration we should reduce the shoots now to considerably more than half their length with the object of promoting strong growth.

**Protecting Roses (Merchant).**—Wips of hay or anything of that kind placed among and round the lower parts of the branches are very useful in severe weather, but they must be removed as soon as the frost departs. The browning of the ends of the branches is of no consequence, as this will be out off in pruning. If the weather is mild towards the end of the month shorten all the shoots made last year to within about 3 inches of the base of each, cutting to good buds that point in the direction you would like the growths to take for producing well-formed heads or plants. By shortening to buds pointing inwards the growths are too crowded in summer. It is not necessary that every shoot be left 3 inches long, as some start from a lower part of the stem than others, and if strong may be left a little longer, but any that are weak should be cut more closely, say to 2 inches, medium shoots 3 inches, strong 4 inches, for newly planted Roses. We do not apprehend injury to the stems, still you cannot err by letting your man twist some small haybands, and coil these neatly round, allowing them to remain for a considerable time, for besides protecting the stems from frost now they conserve the moisture in dry weather in spring.

**Alternantheras (Idem).**—Thousands of these plants are grown in boxes in the manner you propose, and planted from them direct to the beds in

June, or when the weather permits. They should have a temperature of not less than 60°. The variegated Mesembryanthemum may be treated in the same way, but soil does not adhere to the roots so well. If you can dig some turves 2 inches thick or so, char the grass sides, cut into 2 inch squares inserting a cutting or rooted plant in each, with sand falling in round it, and pack these squares closely in boxes, covering with leaf mould or light soil, the plants will be in excellent condition for transplanting in due time. We are glad you find the Journal so helpful. Not a few persons hesitate to ask simple questions lest they should betray their own incompetency. It is just those who need instruction that we desire to aid. A reply on page 142 on starting Vines, will afford you safe guidance. We will readily answer any questions on matters on which you may need instruction.

**Exhausted Vines (D., Hants).**—As the Vines in the outside border are in such an exhausted state, and you have convenience for making a border inside the house, we should not lose a season in attempting to renovate them, but make a border 3 or 4 feet wide in the house, of good soil, building the front of the border with turves, procure some good canes at once and plant when growth commences, cutting out some of the old and apparently nearly useless rods to afford room for training young canes. It would not be advisable to shorten the young Vines for planting at this season of the year, as bleeding would most likely follow; neither would it be desirable to allow all the buds to grow, as this way you would probably have a great number of very weak laterals. We should rub off the buds down to where it would be convenient for fresh growths to start, and not until these had attained a length of several feet should we remove that part of the canes divested of buds. In this way you may have very good young canes this year and very strong ones the next. With good cultural attention you would in fact "gain a season" in furnishing the roof with healthy Vines, ever "waiting to see what the old Vines would do this year, and making a new border in the autumn."

**Annuals for Bedding (Oliver).**—Much depends on the nature of the soil and district as to whether annuals can be depended on for yielding a continuous display of flowers. In a thin soil and dry locality the charming annual *Nemophila insignis* is of short duration, whereas in cooler localities where the rainfall is greater it flowers during the entire season. As a rule hardy annuals are not well adapted for bedding purposes in summer. They are beautiful for a time, but often fail when extremely hot weather sets in, at a time when they are most wanted; yet with deep and rich soil, timely thinning of the plants, and picking off the flowers as they decay to prevent seed forming, beds may be rendered attractive. But there are annuals that are not flowering plants, and flowering plants that may be raised from seed that are not annuals, that you might employ for filling your beds. Subtropical plants, such as *Zea japonica*, *Ricinus* *Gibsoni* and *sanguineus*, *Wigandias*, *Eucalyptus globulus* in a young state; *Cannabis gigantea*, or *Giant Hemp*, and *Melanthus major* are very ornamental for certain beds and positions. They are all raised from seed sown under glass and the plants duly prepared for planting. Dwarfier plants similarly raised which are effective by their foliage are the *Golden Feather Pyrethrum*, *Perilla nankinensis*, *Chamaepeuce diacantha*, and *Dell's Beet*. Of flowering plants *Petunias*, especially the striped and barred varieties, make beautiful and lasting beds, the seed to be sown under glass and the plants grown on and prepared for planting out. Equally suitable is *Phlox Drummondii* raised in the same way. *Verbena venosa* sown at once and strong plants provided by May will flower until severe frost occurs; it makes an effective purple bed. The ordinary florists' varieties of *Verbenas* are readily raised from seed and flower freely in the autumn (the plants growing more freely than those from cuttings) and make good mixed beds. For large beds *Zinnias* are extremely gay. The seed should be sown under glass, but not too early, or the plants will be "drawn." *Ageratums*, both tall and dwarf, may be raised in the same manner as *Petunias*, and they will flower freely the first season. Stocks may be raised the same as *Zinnias*; they make gay and fragrant beds, but do not continue entirely through the season. *Asters* make gorgeous autumnal beds. The seed is usually better sown thinly in very rich light soil under handlights about the first week in May than sown in pots placed in heated structures at an earlier date. *Tagetes signata pumila* raised the same as Stocks makes a close yellow bed of long continuance. Of hardy annuals not many flower for a great length of time if the summer proves hot and dry. The best for bedding is *Saponaria calabrica*, which makes the most charming pink beds imaginable. The white variety also makes pretty beds or edgings. Sow in March in the beds, and thin out the plants so that they can assume a branching habit. For a rich blue or violet bed no annual equals *Convolvulus minor tricolor*. Sow and treat the same as advised for the *Saponaria*. By picking off decayed flowers and applying liquid manure as required the plants flower throughout the season. For producing scarlet, crimson, yellow, and buff beds grow the different varieties of the *Tom Thumb* section of *Tropæolums*, often mis-called *Nasturtiums*. The seed may be sown in the beds or in rich soil in the reserve garden and the seedlings transplanted. *Godetia Lady Albemarle* makes a singularly rich bed, but does not always continue so long as is desired. In some of the beds you might plant such gay and free-growing *Gladioluses* as *branchleyensis* and some others which would grow above such plants as dwarf Stocks and other annuals, and would commence flowering when the annuals were fading. Then for small beds *Lobelias* of the blue and mottled varieties are very suitable. With such plants as we have named, properly raised and well cultivated, you may render your garden gay in the manner which you appear to desire. It is of great importance, however, to remember that when annuals are grown so thickly that they cannot branch and spread, their beauty is necessarily of short duration; for when each plant has only room, as is often the case, to produce one stem, the flowers at the summit cannot be succeeded by others to continue the display.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. *Woodbine*.—*Acacia longifolia*.

## SEED TIME.

MARCH came in with frost and snow, giving to the land the aspect of midwinter rather than that of the first month of spring; but with high drying winds and the sun daily rising higher and higher snow and frost cannot long retain a hold of the soil, and the sowing of spring corn must now be done as the soil becomes dry enough for the drills and harrows. On heavy land naturally retentive of water sowing is often so much retarded that a light corn crop is the result, and it must be owned that old unwieldy implements add to our difficulties in the culture of such soil, as in point of fact they do in a certain degree in any soil. Last autumn Wheat-sowing was much hindered by wet weather. We were out on a heavy land farm once during that time, and saw Wheat being sown with a huge old drill with one horse in the shafts and two horses in front, and so heavy was the work that the shaft horse had to be changed repeatedly.

Nor is this an extreme case. Even with two pair of sh. fts and steering gear it is a common thing to see three horses to a drill, and it is taken as a matter of course that there shall be two men with it. Now we may reasonably assume that farmers must regard as a boon the introduction of a drill by means of which we may not only dispense with a man and a horse, but may also get through the work quicker and better than we have hitherto been able to, and it is our object to call attention to such an implement.

We were asked quite recently to inspect the Chadborn and Coldwell Company's Excelsior Corn, Seed, and Manure Drill, a new introduction here, but which has for some time

Fig. 36.

been in use upon many large farms in America. It is precisely the great extent of farms in the United States and the necessity for economical and expeditious labour that has sharpened the wits of farmers and implement makers there, and led to the invention of such implements as the Excelsior Drill. In this drill we found strength and lightness combined so well that with a pair of horses driven with reins from behind, one man can manage the implement and horses with ease and do the work well and quickly. It will sow any kind of seed from Beans down to Turnip seeds equally well, the distributors being adjustable to any given quantity by the simple movement of an arm or lever, and by means

Fig. 37.

of a dial and pointer the quantity sown per acre is shown. By another equally clever contrivance the number of acres drilled per day is recorded. It has no cups on wheels as we have in our old drills, but the grain is distributed by means of vertical rotary wheels placed in separate compartments, and as the motion is derived from both or either of the wheels, the drill sows right or left or in circles without loss of motion. This part of the implement is termed the corn drill, and with it we can sow seed of any size by means of the regulator A, fig. 36, one of which is in position over each coulter. The seed box, or rather that part of the drill in the position of the ordinary seed box, consists of a seed compart-

ment in front and a compartment for artificial manure at back, each perfectly separate from and independent of the other. It is claimed for the manure drill that it distributes damp or sticky manures evenly, and this can easily be understood when the distributors are seen in motion, for they are of metal, and the revolving table H, fig. 37, is kept clean by contact with G. There are shut-off slides to the distributors to admit of grain or manure being sown in a given number of rows.

Another separate and independent part of the implement is the grass seed drill, which may be termed a corn drill in miniature. We have therefore here an implement by means of which a man with two horses may at one and the same time sow, say, Barley, artificial manure, and Clover or mixed seed for a two or three-years layer. In no implement which has come under our notice have we found utility, simplicity, lightness, and strength in such admirable combination. Even in the coulters we have a novelty in the spring by means of which they may pass over obstructions without injury. They have reversible steel points, are easily adjusted to deep or shallow soil, and the driver can with the lever raise the coulters and throw the distributors out of gear. An examination of this ingenious implement will convince any practical farmer that it is destined speedily to take rank with the best labour-saving appliances of the day. It will, we think, prove as important at seed time as the self-binding reaper does at harvest, and it is our intention to have one upon each of our large farms.

We have intentionally devoted much of our space this week to a somewhat full but by no means exhaustive description of an implement which lends itself so admirably to the

Fig. 38.

economy of labour and to the application of artificial manure to corn crops. Very little consideration will show the contrast between the manufacture of farmyard manure and its distribution with men, horses, and carts, and the use of home-mixed pure artificial manures applied to the soil by means of this drill, which is represented in fig. 38.

By whatever means seed and manure are sown this year, let due thought be given to so apportion the land that there may be no extremes in cropping, for such a course seldom answers. There should be a clearly defined reason for the sowing of every crop either for home use or for sale, but we must leave the consideration of this important matter till next week.

#### WORK ON THE HOME FARM.

Very trying has the severe weather proved for the lambs, but so far we have avoided losses. Lambing was practically over in our large flock on the home farm when the heavy snow storms set in at the end of February. The forward lambs were out with the ewes in the park, and as there are plenty of belts and clumps of evergreen trees there for shelter we kept them there. The next batch of lambs went with the ewes into our large comfortable lambing fold, sheltered by a thick belt of trees, enclosed by a thick fence of straw, and with plenty of snug pens and straw bedding. The younger and more delicate lambs were taken into a yard with plenty of deep open lodges. With such shelter and plenty of sound nourishing food, lambs may fairly be expected to escape harm from cold weather, and to continue in thriving condition, a liberal diet to the ewes ensuring plenty of rich milk to the lambs. Arrangements had been made for beginning folding some of the ewes and early lambs on Turnips, but we decided to wait till the snow was gone, for although we have lamb cloths to fasten to the hurdle, the Turnip field was in such a bleak situation that we feared the effect of the exposure.

That cows are fast calving now we had pleasing evidence recently in the dairy of one of our tenants—a lady who is rich enough to be able to keep a coachman to drive her carriage and horses, and yet she was

up that morning at 4 A.M. to help make the 80 lbs. of butter which we saw. It is her custom to do so always on churning mornings, and we mention the fact as evidence of energetic action on a Suffolk farm equal to anything we have heard of the doings of the notable wives of Sussex farmers. On this particular farm the calves were being sold as soon as possible, so high a price being obtained for the butter that it was not considered desirable to fatten any of the calves. In this and similar instances such a course is right, but in many others fat calves prove an excellent investment, still a calf a few weeks old being as valuable as many are at six months. In our own dairy herd we only save enough of the best cow calves to add to the herd eventually. All others are fattened for veal as quickly as possible. Be it remembered that such provision for annual additions to the dairy herd is always necessary, for there are failures, if not losses, in every herd. We cannot well confine ourselves to a given number. Barrenness, abortion, old age, and disease must all be taken into account, and a cow with any of such blemishes fails to be useful for dairy purposes, and well for us it is if we are always able to replace such failure with useful home-bred animals, and to avoid having to purchase new cows.

#### FARMERS AND GARDENERS.

YOUR correspondent, "One Who Wishes for Fair Play," asks what capital ought a farmer to command for the satisfactory working of a 200-acre farm? and then answers the question after the stereotyped fashion, or that meeting with general acceptance—£10 per acre, equal to £2000. Now money is at present cheap, the Bank of England rate being 2 per cent. The question is, What is a fair rate of interest for capital invested in farming? Trade is bad, prices are low, an outcome of the spending being in excess of the profits. If a manufacturer cannot get a profit upon each £100 invested it is clear there must be a loss. Relief will be sought in some way—reduction of wages, economy in plant, or the greater utilisation of material. He must be eased in some shape to enable him to manufacture more cheaply, and so meet the requirements of the spending classes, whose means of purchasing are reduced. Suppose a farmer invests £2000 in a 200-acre farm, what interest is it likely to bring him per annum? Deposited capital, money granted for others—bankers, public works, and companies—to work, the depositor taking no risk, and having a first claim, gets 2½ per cent. upwards, rarely above 4 per cent., all high rates showing the riskiness of the deposit. Deposit with risk, or shareholders in public companies get rates of interest varying from 3 to 6 per cent.

Just apply this to farming—£2000 working invested capital should afford a return in proportion to the risk incurred. The risks are inclement seasons and disease of stock, concerning which little preventable measures can be taken, though means can be made available in mitigation of the risk. A bad harvest means loss of crop of an exceedingly variable value. Something must be set aside as a reserve fund to meet such calamities not incidental to manufacture. To get at this we must know the actual loss of the 200-acre farmer from providential causes during the past ten years. Has it been a quarter? Then £500 ought to be standing to his credit at the bank in addition to the £2000 invested in the land; if not, then we must take it from the £2000, and have only £1500 actually available for future investment, for all loss of active capital means drawing on the reserve; and if there is no reserve whence is the money drawn? From the capital? Then the interest, to say nothing of the inadequacy of the capital for the working of the land, must be in proportion; instead of interest on £2000 we have only to look for interest on £1500, with lessened output in produce. The risk in farming is double what it is in commercial enterprise of a manufacturing character. Bad seasons and losses from disease are clearly not applicable to manufacture, though it is in commerce. In shipping there are high rates of insurance corresponding to the reserve, though provided in a different way, and the house or firm does not go down under a calamity simply because steps have been taken to keep it afloat in case of probable disaster. Is there such an insurance of farmers against bad harvests and contagious disease in cattle?

Taken on an equality with manufacturers of raw material, we have to consider farming as profitable in proportion to the capital invested. Land differs in quality, capability of producing according to the efforts at improvement, and distance from market, or means of transit of goods to or off the farm. This also determines the rent. As the land is, so should the rent and capital be. If poor, wet, cold, and away from market it must of necessity bring a low rental, whilst if near a town or railway it will be under any conditions in better heart from facilities of manuring, &c., and considerably lessened in working expenses, will bring the highest rental, and the rates will be higher. These matters have great influence on capital and on profits, though relatively there is not much difference in the capital invested, only the first turns it over slowly and the other quickly from peculiarity of crop and location. There is a decided difference between them—the capital of the one can only be turned over once in a twelvemonth, whilst the other is turned over two or three times. This as applied to anything is profitable only in proportion to the skill and sound judgment exercised in its application. One farmer has improved stock for dairy or fattening purposes, improvements in implements, the choicest of seed, and uses most of the best fertilisers. The other is not careful about such matters; the time advances, and he cares not to move forward with them, and is found some day in despair. Rents are too high, rates are ruinous—everything advanced but the prices of his commodities—he fails to see that there has been a breaking up of monopolies, a cheapening all round of the necessities as well as the

luxuries of life through the spread of knowledge and improved methods of production obtained in new and enlarged fields.

In farming capital it ought to afford 5 per cent. up to  $7\frac{1}{2}$  per cent. I think it is usually calculated at 6 per cent, which on £2000 is £120 per annum, to which we have to add remuneration for management, or another £120, which is manifestly one-third in advance of the value, as a competent manager can be had for a 200-acre farm at 25s. to 30s. per week; but as a farmer finding his own capital I make due allowance for it, and accord remuneration for the assumed extra care possessed in its application, as it is clear he would have to give a commission as incentive to other if it were to be applied with the strictest regard to profits, which are in proportion to the efficiency. Now 3 per cent. would be all he would get for the money invested, so as to give him no trouble or anxiety; by using it himself it returns 6 per cent. How much of the 3 per cent. is put aside to meet depressions in values, bad debts, and other things that are incidental to all business transactions? Does the former put by any of the 6 per cent. against a rainy day? Three per cent. ought to go to the reserve account, as the money would return that without any exertion on his part, so that he gets a living for himself, a recompense for his management, and 3 per cent. profit on the £2000, or £60 per annum; and this, added to the reserves, is £120 per annum. His capital is doubled—£2000 in the land, 2000 standing to his credit at the bank at the end of some thirteen years if the weather is propitious, and murrain does not prevail in the interim. If the farmer, on the other hand, spends the profits of his farm as realised, then the first adverse season marks his decline. There is less stock, less put in the land, and lessened labour. Relief is sought the wrong way, as a reduction of stock, tillage, &c., is corresponding to a reduction of capital, and the profits are in proportion with the fact that rent and other charges remain the same. The farmer must do one of two things—save or waste, like anybody else.

I make no question of his saving when his sons, after being educated, are made to earn their own living, but if they live out of the farm they live on the profits and contribute in no way to them. It is different if the sons stand in place of some labour that would otherwise have to be paid for; then who would have right to complain? It is the same with the daughters. If they stand in place of servants, save money from being paid in wages, then I grant they are entitled to pianos and every other luxury and enjoyment that their status warrants. The land will only do so much. The landlord grabs, the farmer grabs, and the two have driven away the small capitalists, and caused them, by the industrial energy they were not permitted to exercise at home, to practise thriftily in the colonies with a success enabling them to undersell the grower in the home markets with everything against them except rent and the insecurity of tenure, with compensation for unexhausted improvements.

Treat the land fairly, and it will pay good interest on investments. Revive agriculture, put capital in the soil, and other trades will revive in proportion to the increase of the products of it. It wants capital—utilised, not protected; thrift, not extravagance.—UTILITARIAN.

If "Thinker" takes me to be a farmer, I beg to inform him that I am not, but a spademan; not a kid glove man either; also that I am not connected with kid-gloved farmers. The farmers that I uphold are those that take breakfast in the morning in summer at half-past five, and see their men come and set them to work, also take the care of sheep and stock by being their own shepherds, follow their own drill, and frequently take a day at the manure cart; in fact ready for anything connected with the farm. There are as many good farmers as gardeners or market gardeners, and there is in each branch quite as many bad ones, but do not condemn all for half. "Thinker" states that it is the farmers' remedy that rent and wages must come down, or should come down. Are not all other industries lowering the wages? I see these last three weeks several large firms have lowered their wages from  $7\frac{1}{2}$  to 10 per cent., which is proving my statement, and depend upon it things will find their level, but it is not all done at once. "Thinker" asks if the rents of the labourers' cottages ought not to come down. I wish for fair play all round. Agricultural labourers pay here from £3 to £5 per year, and most of the cottages have a good garden, also keeping a pig. Between 1852 and 1858 not a few large landowners had their estates valued twice. In several cases the rent was doubled, but not a shilling was put on the labourers' cottages here, nor did any farmer wish to have their labourers' rent raised, but I do not think it is so in the towns. There the rents are double the above without any gardens, or if any they are very small, but town cottages are held by mechanics mostly.

I am pleased to hear that "Thinker" spent "one year" in a farm house. I need not remind him of the hours of labour there; but perhaps I had better, lest he may have forgotten. My time was four o'clock in the morning to the stable, and eight hours at the plough, to turn over one acre per day, which all were expected to do, and we left the stable at eight o'clock at night; in winter from five in the morning to seven at night; in harvest no limit to time. This is how I served in the farm house.

Where does "Thinker" see it stated by me that we are to give up growing Apples because of our climate? Here he is contrary to his own thoughts. On page 3 of this Journal he states American Apples are sent 4000 miles to market, have a ready sale, our home-grown fruit going a-begging, we not having selected the right sorts. Then he asks if I was at the Crystal Palace a few years ago, to which I say "Yes," and several times since; also at most of the London shows for the last fourteen years, and have shown and taken prizes. But this is going from the subject. "Thinker" states, at the Palace Show referred to, taking the Apples bulk for bulk—that is, English and American, the

former would, if sold, have realised more money than the latter. Now, by this statement our own home-grown fruit must be the best, therefore it is contrary to his former statement. I stated, and will prove it, that we cannot colour Apples here, except in very few places, like they are coloured in America. The proof I wish to show is, Apples have been sent here from America and Canada by friends connected with the family I serve. The best only were sent, and some were very fine and the colour excellent, but the flavour does not equal our choice sorts. To further prove my statement, I may remark we have had a dozen and a half of eight choice sorts of young Apple trees sent here from America, and though planted on the best land the result is fruit deficient in size, colour, and flavour; also the trees as yet are very shy bearers, otherwise they are very healthy and not too vigorous, but make good short-jointed wood. They have been planted eight years. Why is not Covent Garden the best market for fruit 100 miles from London? Is Manchester, York, Leeds, or Halifax any better? I say, Decidedly not. How is it that the best Celery has been sent to Covent Garden from Yorkshire through the autumn? also there are now scores of tons of Turnips sent to Covent Garden from Yorkshire. I do not agree in sending further north even to St. Petersburg, though I agree with "Thinker" that corn, taking the average, has been as low before as now. I have sold good Barley at 16s. per quarter, but rents were only about half what they are now, and rates not a quarter.—ONE WHO WISHES FOR FAIR PLAY.

SEED SAMPLES.—We have the pleasure to hand herewith for inspection and acceptance our cabinet of guaranteed grass seeds, and are sure you will pronounce it unique in character on account of the very convenient form in which the seeds are shown, as it admits of the case being kept for reference upon the study or library table, and is altogether an immense advantage over the old system of issuing samples in packets, which must not only be partially destroyed to get at the contents, but prevent the seed being handled without loss.—JAMES CARTER & CO.

[The "cabinet" is an extremely neat box, comprising eight small metal boxes with glass lids, each box containing a sample of some Grass or Clover seed, and bearing the common and botanical name on a narrow red label. We agree in all our correspondents say about it as a convenient and improved method of sending sample seeds for inspection.]

MESSRS. JAMES DICKSON & SONS' FARM SEED CATALOGUE.—Among other interesting matter in the issue before us is the approximate number of seeds in 1 lb. weight of the principal forage and pasture Grasses, some of which, such as the Meadow Grasses, *Poa pratensis* and *P. trivialis*, being recorded as about 2,582,000.

## OUR LETTER BOX.

Experiments in Agricultural Chemistry (*H. P.*).—Professor Jamieson's views on agricultural chemistry and the results of his experiments are embodied in a series of annual reports of the work of the Associations for the Improvement of Agriculture, which have for some years been under his control both in Sussex and Aberdeenshire. We believe the reports are only printed for the benefit of members of the Associations, and are not sold.

Lame Pigs (*B. B.*).—If the lameness is simply a result of exposure to damp and cold, warm food and enough dry bedding to enable the pigs to burrow under it and cover themselves may suffice. But if the lameness is accompanied by difficulty of breathing and failing appetite at once call in a veterinary surgeon, for it may prove to be swine fever, which is a serious contagious disease, and of which you are bound to inform the local inspector. Six of the best Strawberries are Marguerite, President, Sir Joseph Paxton, James Veitch, Dr. Hogg, and Loxford Hall Seedling.

## REMARKS.

28th.—Cloudy all day, with occasional sleet.

1st.—Sleet and fine snow on ground, and falling all the morning to a total depth of  $1\frac{1}{2}$  inch; it fell also most of the afternoon, but melted as it fell. Heavy rain in evening.

2nd.—Cloudy early, with a little sleet; fine morning, afternoon cloudy, sleet at night.

3rd.—Alternate bright sun and heavy snow; windy clear night.

4th.—Very cold, but gloriously bright.

5th.—Very bright morning, cloudy afternoon.

6th.—Fine and bright early, shower of snow and sleet between 11 A.M. and 5 P.M.

Not quite so cold as the previous week, but the temperature still far below the average.

—G. J. SYMONS.

### THE CULTIVATION OF MELONS.

[A paper read by Mr. W. Bardney, Norris Green Gardens, before the Liverpool Horticultural Association, March 13th.]

**W**HETHER Melons are grown better at the present time than formerly is of little moment, but they are grown with less difficulty, and their culture appears to be better understood. With properly appointed structures there is no difficulty in maintaining a supply of ripe fruits over a period of five clear months—that is, from the end of May until the end of October. They can be produced two or three weeks earlier, and the supply kept up well into November, but only those who have the very best of convenience for raising plants can obtain ripe fruits so early, though to have them late in the season is not so difficult. Those who cultivate the Melon only in hotbeds and frames must be content with a late supply of fruits.

To have the fruit ripe early in the season much depends upon the structure available for the purpose. I prefer a narrow lean-to house on the side of a wall, with top and front ventilation, and if there is a shed behind it all the better. The roof must have a moderately sharp pitch, so that every ray of light and sunshine would be able to reach the plants. The hot-water pipes provided should be as evenly disposed in the house as possible, and sufficient to maintain a temperature at night that will not fall below 70°. The pipes employed must be capable of doing this on the very coldest night without being overheated. Hot-water pipes overheated are injurious to the plants, and often result in the plants becoming attacked by red spider. Provide bottom-heat pipes so that the heat if desired can be raised from 80° to 85°. The piping required depends upon the size of the structure, and as these differ so widely it is unnecessary to enter into details. The arrangements of the house are, however, important and must be considered. In houses such as I have alluded to, say 8 or 9 feet wide, there is generally a bed 3 to 4 feet wide extending from the walk to the front wall of the house, with pipes to the front and probably in the walk, with bottom-heat pipes in the bed. Melons can be successfully grown in houses with such arrangements, but to my mind these are not the most satisfactory; first, because it is unnecessary to fill, say, a bed 3 feet wide with soil in which to cultivate these plants; and secondly, because the front portion of the border where the plants are generally placed is several degrees colder by contact with the front wall early in the year than the remaining portion of the bed of soil. To remedy this a second wall (4½ inches wide is sufficient) should be built one foot from the outer wall, or sufficiently far from it that one or two of the surface pipes can be conveniently fitted between the two. Another wall of the same size should be built the whole length of the bed and 18 inches from the former. It will thus be seen that the wall bordering the walk would be 4 feet from the front wall, and the bed practically 3 feet wide divided down the centre. Two pipes would be ample for bottom heat, one in each bed, the flow where the Melons would be planted and the return

in the other. The upper surface of these pipes should not be more than 18 or 20 inches from the top of the walls. The pipe in the bed nearest the walk could be used to assist in maintaining the surface heat if the bed was covered with an open trellis, but this bed would be filled with cocoa-nut fibre refuse or some similar material for plunging and propagating purposes.

For second and later batches of fruit narrow span-roofed houses would be preferred, and the extra wall to the front in this case could be dispensed with. In this case the houses are best with their ends facing north and south. But when the season has fairly advanced Melons can be grown successfully in any glass structure, whether large or small, as long as drip is prevented, light and sunshine can reach the plants, and the requisite heat is maintained.

Melons can be grown and ripened in four months from the time the seed is sown. The first crop will take a little longer, and if seed is sown on the 1st of January the fruit will probably not be ripe on the 1st of May, but they will not be much later if no time is lost and the first female flowers fertilised. To grow plants from seed sown at the time named the cultivator must have a close warm house in which to raise his plants, and a steady bottom heat of 80° to 85°, with a surface heat of 70° to 75° until the plants are ready for placing out, and this temperature should be continued until the fruit is ripe. Young Melon plants grow slowly during the dull sunless days of the first month of the year, and without the best convenience it is useless to sow the seed until three weeks or a month later. If seed is sown about the last week in January the plants with fair accommodation will grow freely, even rapidly, from the middle of February, and fruit will be ripe about the 25th of May, according to the season. This is as early as the majority of people have Melons, and the time I am able to produce them with the means and conveniences at my disposal.

The present is a good time for raising plants, and we prefer a hotbed made in the house in which they are to be grown, say in the bed nearest the walk. In this the material can be raised above the top of the brickwork so as to bring them near the light after the seed has germinated and the plants commenced growing. The material for the bed should consist of Oak or Beech leaves that were stored in a shed when dry in autumn, and litter from the stables. If this is properly prepared it is surprising how long heat will be maintained. Leaves are not within the reach of all, but litter can generally be obtained, and this will answer the purpose very well. Collect the litter as soon as it is thrown out of the stable and place it under cover to prevent it getting saturated with heavy rains. When sufficient has been gathered throw it into a heap and turn it daily so that rank steam can escape. A gentle lasting heat is wanted, and not a strong violent heat such as is produced by wet litter. Some may ask when bottom heat has been provided, Why bother with making a hotbed? This is easily answered, for young plants will not grow so freely in the dry heat from pipes as they will in the moist genial warmth surrounding the plants when plunged or standing upon fermenting material.

When the bed has been made and commenced heating the seed may be sown in the centre of 3-inch pots filled with soil, one or two pieces of crock being placed in at the base. Two or three seeds may be placed in each pot, and if the soil is in an intermediate state of moisture when the pots are filled no water will be needed until the seed has germinated. The pots may be stood on the surface of the manure at first and afterwards plunged to their rims as soon as it is certain that the heat is not too strong. The best and most robust plant that comes up should be selected and supplied with a small stake as soon as needed. When a good quantity of roots has reached the side of the pots transfer the plants into others 2 inches larger. Drain them well, using loam with one-third of leaf mould and manure thoroughly warmed, so that no check will be given. When well established in this

size the young Melons may be planted out. It is not half the trouble to raise plants later in the season, for the seed can be sown in 5 or 6-inch pots and the seedlings placed singly when ready into 4-inch pots, and from these planted out in the soil prepared for them. I advocate planting Melons in a small state when the season has advanced, but the first plants grow more rapidly plunged in the warm manure than they would planted out. When a constant succession of ripe fruit is required, say from May until the end of October, a little seed may with safety be sown once a month until the beginning of July.

At the planting-out time it is necessary to consider what system of cultivation is to be practised. There are three—namely, the extension, the modified extension, and the restricted systems. In order to carry out the extension system successfully one or two plants only should be allotted to fill the whole or part of the trellis of the house, according to the space at the disposal of the cultivator. If the house is not large one plant is capable of filling the whole space, and may be either at one end or in the centre. Various modes of training may be adopted. If planted in the centre the point of the plant may be removed when it reaches the first wire, or has gained sufficient strength to produce strong lateral growths, and two strong shoots may be selected and trained horizontally on each side of the stem. These may extend along the base as far as desirable, either until they reach the ends of the house or the second plant if employed, when the points should be again removed. From these horizontal shoots train others upright at distances of about 18 inches. This can be going on near the centre of the plant, even while the horizontal shoots are extending. The shoots first trained up the wires will have reached the top before all are really started from the base, and must be stopped as well as the first laterals that are produced, so that an even crop of female flowers will appear at one time. With many varieties it is very difficult to get the fruit to swell unless all the flowers have been fertilised and have commenced swelling evenly from the first. Such free-swelling and free-fruited varieties as Conqueror of Europe, Eastnor Castle, and others may be set as soon as the plants have attained fair strength, for they will swell fruits set at different times, and thus form a long continuous supply. Another mode of training is to allow the laterals to extend horizontally from the central stem. When planted at one end of the house adopt the same principle of training. In this case the shoots lead away from one side of the plant instead of both, as when planted in the centre of the space to be filled.

Although this extension system has been successfully carried out there are objections which will prevent its general adoption. First, fruits cannot be produced so quickly as by restriction. Secondly, if a plant grown on this system should by any means be attacked by canker or other diseases, the whole of the crop of fruit will be lost; whereas if, as in other systems, more plants are under culture, a part at least of these may escape. Thirdly, it is impossible to maintain by the extension system an unbroken supply of ripe fruit as can be done by the one referred to above.

The modified system of extension is more generally practised, and differs chiefly in the number of plants required to fill the house. Under this method one plant to each light is all that is requisite, while the training, so far as space permits, is nearly the same. Four leading shoots are taken up the wires until they nearly reach the top. The first laterals produced towards the base of each of these shoots are stopped at the first leaf, and generally produce female flowers on the sub-laterals by the time the first laterals towards the top are developed. By this means there is no difficulty in setting the number of fruits required on each plant about the same time, so that they will swell evenly together. Unless large numbers of ripe fruits are required about a certain time it is not desirable to place out too many plants at one time, or it is difficult to maintain a regular supply. If three or four only are planted a succession of fruits on them can be

insured by stopping the whole of the first laterals and setting the fruit on the sub-laterals towards the top of the plants. This system is a reliable one and may be practised with every certainty of success.

(To be continued.)

#### REMARKS ON SOWING VEGETABLE SEEDS.

EACH year that I open the seed hamper I invariably call to mind my thoughts on the first occasion this happened. The seeds were ordered by my predecessor, and a much larger quantity than was needed came to hand. It would have been bad enough if I had made out my own seed order, but the array that met my bewildered gaze quite upset my nerves, and made me wish that I was still a foreman and not wholly responsible for maintaining a regular and continuous supply of vegetables. However, I contrived to surmount the difficulty, and since that time I have become less and less frightened at the many packets of seeds received, and it should be added have gradually reduced both the number of sorts to be relied on as well as the actual quantity of seeds necessary for maintaining the supply. After the decision as to the sorts and quantities to be ordered, the greatest difficulty with the young or inexperienced gardener, amateur or otherwise, is to decide when each should be sown or planted, and it is upon this subject I propose to offer a few remarks. It is true nearly every catalogue, as well as the gardening and other periodicals, contain much useful information for those needing it, but it is possible to consult too many oracles, and I do not believe in the truth of the old proverb, "In the multitude of councillors there is wisdom," simply because horticulturists must necessarily differ so much in every case depending upon circumstances.

PEAS.—I commence with Peas, for the simple reason that the time has arrived for sowing these where the ground is in good working order. It is a great mistake to sow sound seed at all thickly, especially of the branching sorts of Peas. Crowded rows afford a glut of pods, whereas the thinner rows are much more continuous bearing, and therefore the most profitable. The early blue and white round-seeded sorts are not of branching habit, and these may well be sown more thickly, or say in drills 6 inches wide and about 2 inches apart each way. Instead of sowing several of these early sorts, none of which is very profitable or good in quality, I prefer to rely principally upon American Wonder and William I. The former is now cheap and may be grown in pots, frames, at the foot of sunny walls, between the rows of William I. instead of Spinach, or on an open sunny border, the rows being disposed about 15 inches apart. Being a Marrow Pea it is unwise to sow very early or before the first week in March, and even later if the ground happened to be wet and heavy. As it precedes the round-seeded sorts it is apt to spoil the palate for the latter, but that is a fault to be condoned. Our ground being cold and heavy early sowing is out of the question, and we find it advisable to sow a quantity of William I. in boxes about the end of February, placing these in a Peach house and planting out in a warm position when about 3 inches high. These, with a little extra shelter at the outset, invariably yield gatherings before the earliest sown in the open ground. Later on, if there are failures in the rows of choicer sorts, directly this is discovered seed is at once sown of the same variety in boxes placed in gentle heat. After being duly hardened the seedlings are carefully shaken out from the soil and dibbled in where required, and not unfrequently succeeding as well as those sown in the rows. This plan may not be necessary this season, but is mentioned in case blanks occur. Mice are enemies to the Pea grower, but if the seed is moistened and coated with red lead it is not liable to be interfered with. William I. sown on a warm border or in the open early in March will form a good succession to those transplanted, or a close succession to one of the many variously named extra-early round-seeded sorts. Early in March, or as soon as the ground is in good order, is a good time to sow a row or more of a good second early successional sort, such for instance as Telephone and Criterion, or Stratagem and Wordsley Wonder, the same sorts being sown again directly these are showing through the ground. This plan of sowing two sorts at a time, one being earlier than the other, at about fortnightly intervals, up till the end of June or early in July, rarely fails to maintain an even supply unless poverty of the soil or drought induces premature cropping. Good second early sorts are Telegraph, Telephone, Paragon, Stratagem, Nelson's Vanguard, and Bijou, these being closely followed by Criterion, Huntingdonian, Dr. Maclean, Wordsley Wonder, Nelson's Vanguard, Hairs' Dwarf Mammoth, Gladiator, Sutton's Satisfaction, Webb's Challenger, Duke of

Albany, and Hundredfold. For the main and late crops the best are Ne Plus Ultra, Kinver Marrow, Reading Giant, Triumph, Sturdy, Veitch's Perfection, G. F. Wilson, and Latest of All. We grow a small proportion of the above sorts, but it does not follow our selection would suit all alike, and I mention them as being among the best in the long list submitted to us.

Ne Plus Ultra is too often classed as a late sort only, whereas it may with advantage be sown early in March, and will then afford good dishes in about seventeen weeks, or from two weeks to three weeks longer than the ordinary second early and main crop varieties. The most profitable main and late crop variety I obtained from Mr. D. Thomson, and this vigorous, branching, and heavy cropping Pea I have ventured to name Drunlanrig Prolific. Mr. Thomson has grown it for many years—a sure proof of its value, productiveness, and good quality. Wordsley Wonder pleases everybody, while Bliss's Abundance is quite the reverse. Peas make the least haulm, and are most productive when sown on well-enriched firm ground, but in anticipation of dry hot weather the later sowings may well be made in Celery-like trenches, where they can be easily moistened at the root. The rows in every case ought to be about same distance apart as the height of the respective varieties.

**BROAD BEANS.**—If these were properly cooked, or rather served up as they are done here, the husks being removed after the Beans are boiled, they would be more popular than at present, especially with the middle classes. We make no attempt to preserve November-sown Peas during the winter, being content to sow as early in February as the weather and state of the ground permit. If we wanted any extra early we should sow small pots and plant out at the same time as the Peas were transplanted, and have done so repeatedly in order to obtain extra fine pods for an early exhibition. Beck's Dwarf Green Gem is distinct and serviceable, and may be sown thinly in rows 18 inches apart. Early Longpod, an old favourite, is usually dibbled out in double rows about 2 feet apart, and with this, to form a succession, may well be sown Broad Windsor Improved, the latter and Green Windsor being the best for the main crop and late supplies, much the same plan as to the time of sowing, being followed with these as with Peas. By far the most profitable early Broad Bean I have yet grown was kindly sent to me by Mr. D. Thomson, who has grown it for many years, and Veitch's Improved Early Longpod proves to be synonymous with it, the crop of this variety, according to Veitch's catalogue, having unfortunately failed last season. We had extra heavy crops of it and saved plenty of seed. For exhibition purposes Seville Longpod and Carter's Leviathan are preferred, and the seed should be sown on firm rich land about fourteen weeks before the pods are wanted.—W. IGGULDEN.

## THE PRIMULAS.

(Continued from page 148.)

**P. PINNATIFIDA**, Franchet.—A new species belonging to the *Aleuritia* section, and lately found in Yun-nan by M. Delavay, along with fifteen or sixteen others, and described by M. Franchet in the French Bulletin. With perhaps two or three exceptions they are all allied to Himalayan species, and from the descriptions seem to have no very characteristic differences from these types. The one named above is closely allied to *P. Wattii* of King, with more cut leaves and other minor differences. The flowers are said to resemble those of *Erinus alpinus*, only much larger. It was found on the glacier of Li Kiang in July, 1884. It is probable that at no distant date many of these Primroses will be in cultivation in our gardens.

**P. PLANTÆ**, Brugg, 1884.—A hybrid between *hirsuta* × *daonensis*, Brugg, which we have not seen in cultivation. We learn, however, that it is a very floriferous form and well worth looking after.

**P. POCULIFORMIS**, Hook. fil.—Under this name the plant was figured and described at tab. 6582 of the "Botanical Magazine." We are now told, however, that it has been previously described under that of *P. obconica*, Hey, and which in consequence will be the proper name to keep up. It was found by Mr. Mairies at Ichang Gorge in the interior of China while travelling for Messrs. Veitch of Chelsea, and was sent out by them in 1882. Without exception, as far at least as we know, it is by far the most floriferous Primrose in cultivation. A single plant kept growing in a cool house has flowered incessantly for the last two years. It is flowering still, and to all appearance in perfect health, and throwing up vigorous growth. It would make an excellent greenhouse plant, and when better known we have no doubt it will be extensively cultivated for winter decoration. A half-dozen or so plants placed in a group

would make a prominent feature all through the dull months, when plants with this excellent quality are most required. So far as our experience goes it is not likely to prove hardy in the open air unless the winter be exceptionally mild. Damp or stagnant atmosphere where fogs are prevalent seems to be its worst enemy; a covering of glass or handlight proves quite useless in this case. In localities where fogs are of rare occurrence it may perhaps stand in sheltered positions. It grows from 6 inches to a foot high, the leaves all coming from the root, broadly ovate oblong, in some cases almost orbicular, cordate at the base, toothed margins, wrinkled, and more or less hairy. The petioles are from 3 to 4 inches long. Flowers in umbels of about a dozen, surrounded at base with several small narrow bracts. Flowers an inch or more in diameter, lilac varying to almost white. Calyx campanulate, very curious, and hence arises the name *poculiformis*. It ripens seed, but may also be increased by division of the root.

**P. PORTÆ**, Huter (sub-*Auricula* × *daonensis*, Kern) 1873.—Is a very interesting new hybrid, found by Leybold in company with *P. discolor*, which it very much resembles. When cultivated, however, the difference between the two hybrids is more readily recognised, as well as *P. daonensis*. It differs from *P. discolor* in the glandular hairy scape, the entire absence of meal in the teeth of the calyx, and also in the throat of the corolla. Its leaves are somewhat smaller and more freely covered with glandular viscous hairs. From *daonensis* it differs through the peduncles being from two to three times longer than the very short semi-circular bracts, its broader leaves, and the wine-red colour of its flowers. The calyces also are less glandular than that species. In fact *P. Portæ* is but sparingly viscous, while *daonensis* is amongst the most viscous of the Primroses. It is doing well with us on a western exposure in rich vegetable soil kept free with small pieces of limestone. It seems to be a rather slow grower, and to vary with rose-coloured flowers. Native of the Tyrol, flowering April and May.

**P. PROLIFERA** (Wall, "Asiatic Researches," vol. xiii., p. 372).—As yet this is a novelty, having been introduced only two or three years ago, along with other seeds sent from the Sikkim Himalayas by Mr. Elwes, and raised by the late Mr. I. A. Henry of Edinburgh. The first batch of plants from the home-grown seed has come into the hands of the Messrs. Veitch, a number of which we saw planted out in their nursery at Coombe Wood last year. The plants were small and apparently suffering from being too far south, as those at Edinburgh from the same seed were as large again and flowering most profusely. It will no doubt be much sought after when plants become more rife, and we hope to see it play a prominent part in the hands of the hybridiser. It belongs to the whorled-flowered set, and although the European kinds are most desirable in rockeries, they would be more desirable had they from four to six times the quantity of flowers as the present plant has. It is likely also to prove the hardiest of the whorled set, as it comes from a very high elevation, and therefore better able to stand our winters than *japonica*, *verticillata*, or *Boveana*. *P. Kaufmanniana*, Regel, is said to have two or three tiers of whorls; we have not, however, seen it with more than one. It requires a rich soil in a partly shady position. The leaves coming from a short stem are from 6 to 16 inches long, those we have seen an inch or more broad, oblong, running into a broad-winged petiole, irregularly toothed, and the under side covered with a straw-coloured meal. The flower stem is from 1 to 2 feet in height, with five or six whorls of sweetly scented flowers, pale golden yellow, from a half to an inch in diameter, each whorl containing about a dozen flowers surrounded by narrow acuminate bracts. It commences to flower in June, continuing until August. It inhabits the loftiest mountains of Java, from 8000 to 9000 feet elevation. Syn., *P. imperialis*, Jungh; *Cankrienia chrysantha*, De Vriese.

**P. PSEUDO-ACAULIS**, Brugg, 1884 (*vulgaris* × *officinalis*, Brugg) we have not seen in cultivation in this country, although we have reason to believe it is grown on the Continent.

**P. PUBESCENS**, Jacq.—An interesting hybrid between *P. super-Auricula* × *hirsuta*, Kern, or *Auricula* × *glandulosa*, Sering, and said by the former author to have played a prominent part in the origin of the garden *Auricula*. This question is so full of interest at the present time, and is not unlikely to occupy attention at the Conference, that we may be pardoned for giving the views of the more prominent authorities. In the *Gardeners' Chronicle* for 1875, page 806, appears an excellent translation of a pamphlet written by Dr. Kerner. In speaking of *Clusius*, whose great love for alpine plants, and *Primulas* in particular, is well known. He goes on to say that *Clusius* endeavoured to naturalise in his garden a considerable number of the alpine species, especially *P. Auricula* and *P. glutinosa*. To the whole of these species so introduced he gave the name of *Auricula Ursi*, distinguishing each of the varieties or species by separate numbers. Of all these transplanted species *Clusius* finally succeeded in naturalising only two—the *Auricula Ursi* 1, or *P. Auricula*, and *Auricula Ursi* 2, or *P. pubescens*, roots

of which he transmitted to his friend Van der Dipt in Belgium, whence they spread over Germany and were known in Strasburg in 1595, and by the middle of the following century had come into general cultivation throughout continental Europe and England. Of these two Auriculas, however, the P. Auricula being a true species showed but little tendency to variation, was comparatively neglected, and in time died almost entirely out of cultivation; while P. pubescens, which is a natural hybrid, gave birth to a great series of varieties, the English, or farinose, and the Dutch strains being especially distinct, and by the close of the seventeenth century had become one of the most valued of all cultivated plants. The name Auricula did not originate with Clusius, but is used by Matthioli in 1555, and even by earlier writers. Clusius gathered P. pubescens in the neighbourhood of Innsbrück, then about 1794 in the Tyrol by Wulfen, and then again in 1867 by Prof. Kerner apparently in its original habitat near Innsbrück. In reference to the other side of the question Mr. Baker, who has given considerable attention to the subject, published in the *Chronicle* of June, 1885, his views of the origin of the garden Auricula:—"From the widely spread and well-known P. Auricula, L.," he says, "this P. pubescens differs in having leaves shortly pubescent all over the surface, and especially on the margin, conspicuously inciso-crenate in the upper half, pubescent bracts, calyx, and pedicels, calyx teeth more acute and as long as the calyx tube, dark lilac flowers, and the whole plant—leaves, bracts, pedicels, and calyx—almost entirely destitute of fine white meal. It seems to me quite impossible to take a walk through any Auricula show with this Primula pubescens in memory without feeling that Prof. Kerner's paper is very far from having exhausted the whole subject. My own view is that a very large proportion of the garden Auriculas are nearer to P. Auricula than they are to P. pubescens, and that the garden Auricula of the present day is the product of a complicated series of intercrossings, of which P. Auricula, Balbisii, venusta, and pubescens have also entered." Stein believes that our very dusty English Auriculas are not only relatives of P. pubescens, but we get them through the fertilisation of this hybrid with P. Palinuri. P. pubescens grows from 3 to 6 inches in height, flowers in umbels, a dozen or more in each, dark lilac or brilliant rose colour, with golden-yellow eye; leaves obovate, cuneate, 2 or 3 inches long, pubescent all over, the upper half being crenate. Tyrol. Flowering April and May. Syn., hirsuta, Vill.; rhaetica, Gaud.; helvetica, Don; alpina, Reich.; villosa, Ait.; microcalyx, Lehm.—D.

### OPEN-AIR PEACH CULTURE.

Not a few persons appear to imagine that Peach trees cannot be grown to fruit so satisfactorily on open walls as they used to be in years gone by. This is erroneous, and the sooner the delusion is dispelled the better. The want of cultural attention is the foundation of the imperfect examples of Peaches seen at the present day on open walls. Before entering on details I wish to say a few words on the training of the trees. We frequently hear it stated that gardeners in past days spent much more time than was necessary in the production of their trees, that the culture now practised is more to the point, and that the results, according to the time spent on the trees, are superior. This is the argument at the present day, but is it not more fanciful than real? The originators of so-called new methods generally go to extremes to prove their case, and their ideas are taken for granted by younger men and used as a cloak to cover slovenliness in management. Whether the old gardeners went slashing about their trees wholesale for the first four or five years of the trees' existence, as we are led to suppose they did, I do not know; but as long as I have been connected with private gardens and nurseries the trees have been grown on the rational principle, and I maintain that they can be grown under this system so as to produce far more satisfactory results as regards fruitfulness, and with far less trouble in after years, than when the trees are of irregular shape and the branches badly trained.

During the first years of the tree's existence it takes no more time whatever to lay the shoots and main branches straight, and to keep the tree well balanced, so forming a handsome example, than if the shoots are laid in anyhow and often crooked, as some suppose to save time. Well-balanced trees with straight branches denote rational treatment, and instead of being "tree worship in its worst form" is tree culture in its best form. I maintain that not only is no time wasted in securing the shoots straight as growth proceeds, but in after years not nearly so much time is required to keep the trees in order as those treated in the higgledy-piggledy fashion, and well-trained trees are certainly not less productive than those fastened to the wall irregularly. I have more than once been amused when showing well-balanced trees to strangers to hear them remark that they "could not spare time to train them so well;" but they could find no fault with the crops.

The soil best adapted for the Peach is a calcareous loam, with the under stratum either of the chalk or limestone formation. Where a soil of this description does not exist naturally the site must be prepared similarly to when making a border for indoor culture, care being especially taken with the drainage, as a dry subsoil means warmth at the roots. In moist parts of the country, and where the soil is cold or clayey, the border should not be more than 20 inches in depth and 8 feet in width, and should be made above the level of the ground. The fertility of the soil must be maintained by top-dressings. I have now in mind a grand wall of Peach trees, which bear heavy crops annually. The border is of the same width and depth as stated above, and is above the ground level. Their culture can be summed up in a few sentences: Protection from frosts whilst in bloom, freedom from insects, plenty of water during the summer months if the weather prove dry, mulching with equal parts of lime rubbish and well-pulverised horse manure, the growths and main branches evenly distributed, and after the fruits are gathered the old bearing wood cut out, so that the bearing wood for next season receives full light and air are essential. On warm evenings through the summer months the foliage is much benefited by a good shower-bath of tepid soft water applied with the syringe, or, what is better, the garden engine. We have used clear soot water with marked benefit to the foliage, and it also tends to keep red spider away. Black aphides are especially to be guarded against, for when these gain a footing it is "all up" for the present and following season's crops. The best antidote we have used is a quart of tobacco water to three gallons of soft water, heated to the temperature of 120°; syringe the trees with this on mild evenings, and early the following morning, before the sun gains power, syringe with clear water.—A YOUNG.

### ORCHID NOTES.

MANURE FOR ORCHIDS.—I must congratulate "An Amateur" on the able manner in which he is dealing with the "Hints on Orchid Culture." I have read his notes with much interest, and now write to give a little of my experience with manures for Orchids.

It is very likely that there are various manures most suitable for various genera of Orchids, but my experience is very limited both in regard to the number of manures and genera experimented upon. The only artificial manure I have tried is "Clay's Fertiliser," and its effects on terrestrial Orchids have been beneficial, but when used for several epiphytal species it has killed the sphagnum and been of doubtful utility to the plants. A friend had a similar experience with another artificial manure upon several species of Odontoglossums—in fact, their roots were partially destroyed; but, as I am not quite sure as to the identity of that manure I will not attempt to name it.

The manure I have used with great advantage consists of half a peck of soot and half a bushel of fresh horse manure placed in a bag and suspended in a barrel of rain water. This liquid manure is used in varying strength for all kinds of stove and greenhouse plants as well as Orchids, and for general utility and safety I find it difficult to surpass. In its application to Orchids the terrestrial kinds have it once a week; when in full growth the colour of strong tea, or if given twice weekly it is more diluted. This same manure I have applied advantageously to *Cœlogyne cristata*, *Miltonia spectabilis*, *Cypripedium barbatum* and *C. insigne*, *Oncidium ornithorhynchum*, *Odontoglossum Schlieperianum*, *Lælia purpurata*, *L. anceps*, *Pilumna fragrans*, *Stanhopeas*, *Acropora concolor*, *Lycaste Skinnerii*, *L. gigantea*, *Brassia verrucosa*, *Zygopetalum Mackayi* and *Z. maxillare*, *Epidendrum vitellinum majus*, *Phaænopsis Schilleriana*, *Dendrobium crystallinum*, *D. chrysanthum*, *D. chrysotoxum*, *D. cretaceum*, *D. crassinode*, *D. Devonianum*, *D. fimbriatum oculatum*, *D. macrophyllum (superbum) giganteum*, *D. nobile*, *D. Paxtoni*, *D. Parishii*, *D. primulinum*, *D. heterocarpum philippinense*, and *D. Wardianum*; and in all cases its use has been attended with most satisfactory results. I believe the cause of the improvement is the ammonia the manure contains, and possibly by a per-centage of carbonic acid, but that would be very small.

What is the reason that many Orchids appear to have a great liking for charcoal? Is it not because the carbon of the charcoal has an affinity for the ammonia in the atmosphere, and thus absorbs and retains it for the use of the Orchids? There is a very common impression amongst gardeners that plants show a liking for charcoal for its own sake, but I am informed that is a popular error.—A NORTHERN ORCHID GROWER.

TREPPO.—In your issue of the 11th inst. your correspondent, "An Amateur," in his very able and interesting "Hints on Orchid Culture" refers to the introduction of Trepho as a substitute for peat for growing Orchids, and perhaps you will permit me to inform your readers of the facts of its introduction. Some two or three years

past when travelling in Bavaria, seeing some remarkably healthy sphagnum growing with a most unusual luxuriance of several inches of that exquisite lively green all Orchid growers desire to see under their plants, it occurred to me to try and chemically treat this moss so as to make it a medium for retaining moisture without souring or rapid decay, and after many experiments over a period of two years I found that by treating live sphagnum with borax, ammonia, and other ingredients, and then pressing it into blocks by hydraulic pressure, I obtained an article that kept quite sweet when up and used for potting, or retained in square blocks, in baskets, or on rafts for a period of eighteen months or two years. After giving this article so prepared a fair trial in potting, blocks, &c., I found even *Sophranitis grandiflora* and its varieties to plump out its pseudo-bulbs when planted on a block of Trepho as I had never before seen under culture in this country, whilst the baskets containing the square block upon which I planted the imported pseudo-bulbs were not dipped frequently for three or four days. Speaking of this to Mr. B. Field one day he begged of me to have a quantity of Trepho prepared for him. Several amateurs and growers having proved its value had been inquiring for the article, hence I had a few tons treated with ammonia, sulphates, borax, &c., on the formula I had previously proved. May I add that Trepho should always be used with the grain or layers perpendicular and not flat, to enable it to give off the moisture more freely?—MARCUS H. VOSS, *De Montfort House, Streatham, S.W.*

### ROSE PRUNING.

MANY an article I have read in the Journal under this heading. My present object is not to advise, but condole. By this time most exhibitors have made up their minds and have fixed plans about pruning; but few, I apprehend, ever anticipated—at least here, in S.E. England—finding it impossible up to now, the middle of March.

I had the advantage of mixing to-day in very high society, from a rosarian point of view, but heard nothing about pruning, though plenty about the effects of the late frosts. It was considered that the frosts of March and the perpetual changes in February have done far more damage than all the sharper earlier frosts of the season, and that when pruning does begin it will be necessary in many cases to cut very close.

One friend had made a feeble attempt to prune, but had been immediately snubbed by the weather, which has been, indeed, exactly my own case also. Neither was it held there was much present hope of change of weather, though that is entering on a most perilous path of prophecy.

I was much tempted to take away the fern at my usual time, the end of February, but was dissuaded by my gardener, who asked me "how I should like to part with my own great coat." I am now rejoicing in his higher wisdom. When pruning can begin it will come with a rush, and the captains of thousands will have to call for assistance. Perhaps they already reckon upon doing that.

The simple rule, the good old plan,  
Sufficeth them.  
That they should wait who have the power,  
And they should prune who can.

—A. C.

### SYRINGING VINES.

IN your last issue "A Kitchen Gardener" recommends syringing Vines in order to obtain a humid atmosphere. He says, "On dull days the Vines should be syringed at least once, and in bright weather they should be syringed twice." Is this right? I would ask. It cannot be denied that a humid atmosphere is most important to the well-being of the Vines, but I have yet to learn that the best way to attain that end is by syringing. I have been a witness to many evils resulting from the use of the syringe on Vine leaves and fruit, especially where only hard water could be had; and many gardeners are not able to obtain soft water, which is undoubtedly best for all purposes.

For my own part I would much rather bring about the desired end by damping the paths and all available spaces, but not the foliage. By this practice and keeping the roots well supplied with water I was able to go through last season without red spider or any other insect on the Vines under my charge, and long after the fruit was ripe and cut they retained their foliage green and healthy.—JAMES POUND, *Reading.*

### SOLANDRA GRANDIFLORA.

THIS belongs to a splendid genus of plants named in honour of Daniel Charles Solander, LL.D., a Swedish botanist of great celebrity. He was the companion of the renowned Sir Joseph Banks in the memorable voyage of discovery round the world, and was the collector of the botanical notes made during that expedition, and which are now preserved in the British Museum. The plant, a bloom of which we figure, is by no

means commonly to be met with in cultivation. This is not, however, because it is not beautiful, but rather that it is somewhat shy in producing its flowers. Besides the flowers being strikingly attractive by their Brugmansia-like form and pale yellow colour, the foliage is also agreeable, and the plant is worthy of being cultivated in our stoves. For a number of years after its introduction in 1781 this plant did not bloom. It was propagated and grew luxuriantly. The treatment necessary for the production of flowers was found out by accident, a plant being overlooked and left in a dry stove at Kew. This plant produced foliage of only moderate luxuriance, and produced a flower at the extremity of every shoot. This suggested that a period of rest was necessary, and on its

Fig. 39.—*Solandra grandiflora*.

being afforded the difficulty in blooming this plant vanished. The plant is propagated from cuttings, which should be grown on in loam and peat in a brisk heat and with liberal supplies of water until it has attained a good size. Water should then be gradually withheld until the leaves wither and drop off by drought, and the plant will seldom refuse to flower profusely. It is a free-growing plant and a native of Jamaica, thus requiring heat to grow it, yet a distinct season of drought and rest to induce the production of its beautiful flowers.—S.

### NOTES ON THE WEATHER AND VEGETATION.

WE have received numerous communications concerning the weather from correspondents in various parts of Great Britain, of which we can only publish the following this week. It will be seen from them that low temperatures have been experienced in several districts, while in the neighbourhood of London the most severe frosts have ranged from 10° to 20°.

The weather has continued dull and cloudy during the past week, a keen north-easterly wind prevailing generally. Green vegetables are rising to extravagant prices, and no progress in sowing for spring crops can as yet be made.

AT a meeting of the Royal Botanic Society held on Saturday last, Mr. W. Y. Low in the chair, Mr. C. Schoell was elected a Fellow of the Society, and the names of several others read for ballot at the next meeting. There was exhibited at the meeting a series of charts from the Society's Sunshine Recorder, from which it appears that the total of sunlight registered during February was no more than seventeen hours, or less than one-fifteenth. During March, however, only two days as yet have been sunless. Mr. G. J. Symons, F.R.S., gave some remarks upon the severity of the recent weather. He pointed out that the mean temperature of every week this year at Greenwich had been below the average, and as much as 7° or more below in several of them. Mr. Symons exhibited a diagram representing the temperature at 1 foot below the surface for each day this year, which showed that from January 1st it had almost continually fallen until the present date, and is now 11° colder than on the corresponding date in 1882. Moreover, the temperature at 3 feet below the ground, 33.4°, is as low as at 1 foot, showing a penetration of low temperature extremely unusual, and due solely to the persistency of the low temperature, for no short frost has ever produced such an effect. In the discussion upon the effects of the extreme cold upon vegetation which followed, Mr. H. S. Manning said there was every reason to hope that by retarding the flowering season of our fruit trees the cold would benefit agriculture.

MARCH, 1866, up to this date (9th) will be long remembered in this part of Derbyshire for its extreme coldness. The following temperatures were registered in the kitchen gardens during the past few days:—March 4th, at 7 A.M., 27° of frost; 5th, 26°; 6th, 18°; 7th, 34°; 8th, 26°; 9th, 12°.—OWEN THOMAS, *Chatsworth Gardens*.

THE wintry weather is becoming with us a somewhat serious matter. We have still, as we have had for a long time, a considerable depth of snow, covering everything and preventing all ground work. Green vegetables have almost entirely disappeared and cannot be replaced for a long time to come. There is still no sign of the cold weather leaving us. Our thermometer at its lowest point a week ago was down to 10°. At Wakefield it appears to have been even more severe than with us, and I am told they have a greater depth of snow.—W. K. WOODCOCK, *Sheffield*.

THE lowest point registered here each night between 6 P.M. and 6 A.M. from March 5th was as follows:—Friday morning, 9° above zero, 23° of frost; Saturday, 7°, 25°; Sunday, 5°, 27°; Monday, 1°, 31°; Tuesday, 11°, 21°; Wednesday, 11°, 21°. We are getting well into the fourth month that the lakes here have never been clear of ice.—FREDK. TAYLOR, *The Shrubbery Lodge, Welbeck Abbey, Worksop*.

ALL who take an interest—and who do not?—in the state of the weather must be struck with the severe aspect it has assumed since the beginning of the present year. Nor does it as yet give signs of relaxing its grip—24° of frost on the morning of yesterday and 14° to-day, the ground covered with snow, in many places as deep as the dykes are high. Farmers, especially Highland sheep farmers, are to be deeply commiserated for the enormous cost they have been obliged to incur to save their stock from perishing, and the nation generally must suffer severely in its best interest unless we get an immediate and radical change of weather. From such signs as are at all reliable, I fear this prospect is not well founded. In our latitudes we are, as is well known, very dependent for the genial and growing warmth of our climate on the influence of the Gulf Stream. Scientists have proved that this influence has varied at different periods of the earth's history from little to much, and I fear there are indications that it is going in the former direction at the present date. For twenty years we have not had more than three thoroughly genial, warm, growing summers—such weather as leads to the production of full agricultural crops both as to quantity and quality. I appeal to farmers to say if in this I am wrong. Thirty to fifty years ago we had bad seasons, but they were the exception then; they are the rule now, and good ones the exception. Low as the prices of agricultural produce are, and heavy as this must bear on the prosperity of agriculture, the position is greatly aggravated by a diminution of at least one-third of what, under more favourable circumstances as to weather, should have been the return from the soil. This has more to do with the present dullness of trade than is generally suspected. So much for the past. What of the immediate future? I confess that I do not think the prospect bright. Men who have made the subject a study show that our part of Europe derives one-third of the warmth of its climate from the warm water of the Gulf Stream and two-thirds from the sun. The sun is likely to do his duty as of old, but I fear the Stream is failing in its performance.

The circulation of the water of the ocean known as the Gulf Stream is great or less in proportion to the difference of temperature of the water at the Equator and the Arctic Circle. Now, during the present winter the weather has not been exceptionally cold in the Arctic regions from a normal point of view, while it has been exceptionally cold, for instance, in the neighbourhood of the Gulf of Mexico, from which quarter the warm water of the Gulf Stream proceeds across the Atlantic to our shores, by its influence both mitigating the severity of our climate and adding by its

humid warmth to the produce of our soil. When the waters of the Equator are very warm and those of the Arctic Circle very cold, the rush of the warm Stream in our direction will be greater, and *vice versa*. The denser cold water of the Arctic by its gravity falls into the Gulf of Mexico under the warm water, and, so to speak, pushes it out, compelling it to come across the Atlantic and occupy the space it has left—exactly guided by the same law which makes heating by hot water with boiler and pipes possible. Now, what are the prospects that this circulation will be defective this summer? The first is that there has been some defect in the case of the boiler—the Gulf of Mexico—for in its own immediate neighbourhood there have been severe frosts; the Oranges frozen on the trees, and the trees that have stood a hundred years killed in Florida; in New Orleans, men frozen to death and trains stopped by snow. This is cold unprecedented there, and if this was so on land, it is fair to infer that the sea came under the same influences; consequently we cannot expect so liberal a flood of warm water from that quarter as if the winter there had shown no abnormal signs; and in the second place, there is no reason to suppose that the water of the Arctic Circle is abnormally cold at present.

I, however, sincerely hope I may be mistaken, and that in spite of appearances we may have one good, genial, old-fashioned summer, giving us a bountiful harvest, which I believe will do more to revive the drooping interest of Europe than mere legislation can.—WM. THOMSON, *Clovenfords, March 8, 1886* (in the *Scotsman*).

THIS season will long be noted, and for years no doubt will be referred to, not on account of any extreme severe frosts, for we have had no zero records this winter, but for the long-continued cold weather which with frosts have prevailed more or less since last October. There has not been above two nights here since the new year that the thermometer has not fallen below freezing point; that was the last week in January, when no doubt many others beside myself took the opportunity to get in the earliest crops of Peas, Beans, and Spinach. It is doubtful whether these would not have been as well out of the ground, for ever since that time we have had a continuation of cold weather with snow and frosts ranging from 2° to 20° every night, and only on bright days, when the sun now has sufficient power to cause the temperature to rise above freezing point—although it has been freezing hard in the shade—has there been the least relaxation, and as I write (March 15th) there is not the least sign of a change for the better, the wind still blowing keenly from the north-east.

This has been a trying winter for gardeners, and many have felt the ill effects of it. To what extent the more tender shrubs and plants have suffered will not be discerned until later in the spring. In the kitchen garden we are feeling the more immediate effects. Vegetables are now at a premium, anything in the way of Sprouts or Greens selling readily at 3d. or 4d. per lb. at the greengrocers. Spring Cabbage plants are disappearing from the beds, and I am afraid there will be very few left alive, and what there is is much smaller than they were in November. Winter Lettuces are gone or going, the hardy Brown Coss alone struggling for existence, and Winter Spinach and other vegetables are in the same condition. Those who have taken the precaution to sow some early varieties of vegetables in boxes and placed in gentle heat, ready for pricking off into other boxes or frames when large enough, will find the benefit presently. Such varieties as Ellam's Early Cabbage, Early Forcing Cauliflower, Early Paris Market Lettuce, a little Spinach sown in 60-pots and placed in a cold frame, American Wonder, or Veitch's Selected Early Pea, and a few Early Mazagan Broad Beans, should be sown on strips of turf and placed in a slight heat, to be hardened and planted out when the weather is favourable. I should advise those who have not already done so to lose no time, and thus try to tide over the emergency, for I am afraid there will be many gaps in the early-sown out-of-door seeds this spring.

Though we despair when looking at our losses, or frown at the want of sun for early forcing, and feel grieved at the crippled condition of the flowers of the choicer occupants of the house for the want of solar light, there is still a bright side to the question. Although the weather has been sadly against those who have had landscape work or alterations in the shape of turf-laying or shrub-moving or planting to do, we have not had such a season for years for wheeling or carting manure on land, and for shrubbery cleaning, as we have had this winter; and many an old rubbishy corner or shrubbery, I venture to state, has been cleaned out, that has been neglected during the last few open winters, and the land no doubt will reap the benefit of it. Everything at the present time is as backward as in the first week in January, no signs of life in anything except the Snowdrops and Winter Aconites, a Crocus or two in the more sheltered places, a stray flower or two of *Scilla siberica* and *Primulas* out of doors, so with an ordinary run we may look hopefully forward to a good fruit season, as the flower buds are kept back safely at the present time.

To show the disparity between two seasons within a year of each other I append a few notes that were made by me on March the 16th, 1884, showing the condition of plants out of doors at that time after an exceptionally mild winter. They may be of interest to some of your readers. This was noted as the Apple year, when the Apple Congress was held.

The whole winter months very mild, open and dry; the previous day soft, mild breeze with sunshine. This day thermometer 75° in the sun (at night ten o'clock thermometer 50° temperature). Gloire de Dijon on the house has been in flower the whole winter, and is just shedding the last blossoms; Clematis montana on the lodge is throwing out foliage and flower buds, the first buds just opening; Lilacs are showing bloom on the

upper branches; *Berberis Darwinii* is hanging in golden clusters, ready to burst into flower; *Mahonia aquifolia* in full bloom; *Laurustinus* also in full flower and very clean; Red Flowering Currant (*Ribes sanguineum*) bursting out in full flower and foliage, the first flowers open; *Forsythia viridissima* in full flower in shrubberies; *Ceanothus rigidus* and *Berberis tenuifolia*, on a conservatory wall, just showing colour; Almond trees at their best and in full beauty; double Thorns are bursting into growth; the old orange-flowering *Kerria japonica* just going out of flower; the brushwood of the large Elm trees pushing out their green shoots half an inch; the Poplars and Elm trees in flower; Crocuses in full bloom in borders; red and white Daisies are flowering in beds; Wallflowers are in bloom, and some spikes of the old double yellow Wallflower cut to-day; bedding Pansies in beds just pushing up flower buds; Violets in beds at their best; Hyacinths in borders in beautiful bloom; Mignonette is in flower, and have been the whole winter; two standard Plum trees in full bloom; Apricots and Peaches in full bloom on walls; Pears and Apples bursting; Gooseberries are in leaf; Currants coming out fast. Kitchen garden crops.—Turnip tops are a foot high; early Radishes, Lettuces, Turnips, and Spinach are up; early Peas about  $1\frac{1}{2}$  inch high; Veitch's Selected Early is the forwardest, and William 1. next.—C. ORCHARD, *Coombe Warren Gardens, Kingston-on-Thames.*

THE weather in Devon has been and still is very severe, and although there have been several days of sunshine, Dartmoor and the surrounding hills are still covered with snow; and the frost during the month has been very sharp, with cold easterly winds. On the 3rd inst. the thermometer registered 16° of frost; and on the 6th, 15°; and the 10th and 11th 13°. The coldest night that we have had during the winter was on the 10th of December, when the thermometer registered 17°. Notwithstanding the hard frost, we have been able to get in our crops of Parsnips, Onions, and early Carrots on bright days. In some places the Spring Cabbage are almost a failure, and nearly half of the Broccolis have been killed, and those that have been saved will be very late. Apricot blossom, which I have known fully open by the middle of February, is just beginning to expand. The farmers have great difficulty in obtaining sufficient food for their cattle, the root crops being in many places a failure, and instead of grass growing it is diminishing.—L. G.

THE winter has been peculiar on account of its short alternating periods of comparative mildness and low temperatures. Generally, we find a difficulty in getting ice in sufficient quantity for storing, but this season a plentiful supply was secured before Christmas, and several times since quite as large a supply could have been had. We have not experienced such low temperatures as in some years, 20° of frost being our lowest register; but the rapid changes from heat to cold, and again from cold to heat, have been most hurtful to vegetation; *Schizostylis* has been killed, Lettuces succumbed very early in the winter, so did Globe Artichokes; Violets haved it for a while, but gave up in January and are now quite bare. Old Laurels look very bad, and old Roses will have a large amount of dead or half-dead growths to remove. Hardly any spring flowers have as yet bloomed; we have Snowdrops, Winter Aconites, and some Hellebores, but no Primroses, Polyanthes, Anemones, Sisyrinchiums, early Daffodils, nor Pansies, as we have often had at this time.

On the whole the winter has been very suitable for forwarding work. We never had better nailing weather than was experienced in the early part of February; but for the past four weeks it has been almost too bad for anything. We cannot get on to the ground. Frosty east winds make nailing impossible; potting bedding plants, cleaning hothouses, and renovating old implements, stake and label making cannot go on indefinitely, and we find it becoming a pressing question what to do next. Still we are comparatively favoured here. Not so very far away neighbouring gardens were isolated by snow hlocks for days. We hear of one case where the workmen had a week's holiday. Our March register has been low, most nights 6° to 9° of frost, on the 6th 13° of frost, but we hear of from 20° to 29° of frost in a neighbouring county, and in the north of England of 6° below zero on the same night.

As to cropping, we have only Peas and Spinach sown. Two sowings of various vegetables have been made in heated frames, but these never do so well as plants raised in the open. The immediate prospect is that no garden ground work, no seed-sowing or planting can take place with the best of weather for another ten days, and of course that may be indefinitely lengthened should no change occur.

As a matter of course, coals have been going with great rapidity and there is very little to show for it. What a great magician is the sun! and how little can we do to make up for the lack of his favour. Such times teach us how very little indeed. With regard to fruit prospects, Strawberries have been quite blackened; but genial after weather will put that all right. Other hardy fruits, though not yet on the move, we expect to do well if favoured with a fair season. The autumn of 1885 was a lengthened and good one, and it only needs a summer of a like favourable nature to make this a good fruit year like the last. In a season like this we shall take the precaution of erring on the late side with regard to seeding, sowing, and planting.—B., *East Lothian.*

#### SNOWDROP POTATO.

MR. IGGULDEN says (p. 157) that the above Potato is not distinguishable from Snowflake, but I think he makes a mistake. Half a dozen years or more ago Snowflake was grown here for several seasons, and although we found it a heavy cropper it was one of the first and worst

affected by disease. Its quality when cooked was nothyan means first-rate, and, like many more varieties which have been tried here, it was given up. Many cottagers and farmers in the neighbourhood also tried it, and all have given it up for the reasons above named. Three or four years ago, and when Snowdrop was little known, a reader of the Journal in Northamptonshire sent me a few tubers in exchange for some Tomato seed, and he gave it such a good character that I felt sure that I had secured a first-rate Potato, and it has really proved to be so. We have planted more of it every year, and find it free from disease, a very heavy cropper, and first-rate quality. It is also one of the most handsome white kidney Potatoes with which I am acquainted, being of oblong form, and so shallow in the eyes that these are hardly observable. In this respect it differs widely from Snowflake, as this, like the majority of the American sorts, shows a great many eyes rather deeply set in the flesh. In habit of growth, form and quality of tubers, and in general character the true Snowdrop bears no resemblance to any Snowflake I have grown or seen, and I am positive in my opinion that Snowdrop has no right to be regarded as synonymous with Snowflake.—J. MUIR, *Margam.*

#### MIGNONETTE.

THE flowers of Mignonette are always welcome, and where a continuous supply of flowers is required seed should be sown at once in a cold frame. Place the frame in a warm sunny position on a horder, and render the soil fertile by the addition of manure. The soil if moderately dry must be rendered firm, which will prevent the plants making a long straggling growth; if not, it is best left alone, for it is unwise to press the soil closely together when wet. Sow the seed on the surface and then lightly cover it with fine soil, or rake it in. Keep the frame close until the seed has germinated, when a little air may be admitted daily if the weather is favourable, closing it early in the afternoon to push the young plants into growth as rapidly as possible. When the plants are large enough thin them liberally, for nothing is gained by allowing them to crowd one another. Under these conditions the plants will grow rapidly and come into flower long before those sown outside, and the plants grown in pots can be dispensed with to save labour in watering.—D.

#### VINES—BORDERS—SPRING PLANTING.

THOUGH the winter has been severe Vines, both early and late, have started well. Some will attribute this satisfactory state of things to the discontinuance of artificial heat for outside borders, but few question the utility of the moist, genial, ammonia-charged heat of a bed of fermenting materials within the house. I do not advocate covering outside Vine horders with hot fermenting material, at least until the Vines have pushed growth and have active feeders, and roots in outside borders are less injuriously affected in a cold dry winter than in a mild wet one, but some frost resisting material over the border keeps the temperature several degrees higher than when saturated by heavy rains or snow. Good breaks almost invariably result from thoroughly ripened wood, and a condition of the border favourable during rest.

It is doubtful if our Vine horders are not deeper and wider than is essential. In limited borders renovation is more expeditiously effected, and Vines like porous soil full of fresh decomposing food-affording matter. Whenever the Vines in a house begin to fail the roots are deep or the horder has become an inert mass. The remedy is to be sought in the removal of outside or inside border soil in alternate years, so as to prevent loss of crop, shortening the roots, and relaying them in new compost, consisting of rough turfy loam and old lime rubbish, using manure only as a mulch. In this the Vines make stout short-jointed wood, ripening well, and giving compact handsome bunches of fine berries colouring and finishing well.

Where spring planting is contemplated the situation and surroundings should be considered. If the border is high and dry it may be 2 feet 6 inches deep, but in low situations 2 feet is sufficient, the former resting on a foot of drainage, but in the wet site 18 inches depth of drainage is advisable. It is generally considered that anything of an open nature will answer for drainage. That may be if nothing is sought but the passing away of the surplus moisture to the drains. I consider, however, that the drainage has a considerable effect on the result. If we use gravel or stone of a close hard texture it will absorb but little moisture, whereas in broken bricks, old lime rubble, or even chalk, we secure a moisture-holding substance, which is being changed, whereby food otherwise inorganic is made available. Besides, the food retained by the drainage is sufficient to attract and induce a mass of hungry roots to enter it, much in the same way as we find with plants in pots the greatest luxuriance of roots amongst the drainage at the bottom of the pots. The drainage should be of such a kind as will not only allow the water to pass freely through the soil, but be of a moisture-holding calcareous character, though silica is not unimportant, as is evidenced in the employment of brickbats and stone of the sandstone formations. A sprinkling of crushed bones over the drainage is advisable, through affording phosphate, and a sprinkling of charred refuse is serviceable through its potash. Between the drainage and surface I do not think anything necessary but lime, with the silica inseparable from the employment of old moisture rubbish. I have tried stratified borders, but I do not think there is any advantage proportionate to the increased labour entailed in securing thorough and uniform moisture. Loam containing enough grit to keep it open is important. Bones are, no doubt, useful, as also is charcoal, but the chief points are good drainage, a porous soil,

and rich surface dressing. The border need not exceed 4 feet in width, and inside the house, the openings to let the roots pass into the outside border being bricked until the inside border is made to its full extent and occupied with roots, then the openings may be cleared and the roots allowed to pass out into properly prepared outside borders. A 4 foot width of border is quite sufficient for a year, and is far better than a great width of border which the roots may ramble through, but do not fully occupy until several seasons' growth has been made, much valuable matter being wasted.

Vines in a growing state that have been cut back can be planted as soon as the border is prepared. They will grow away at once and under good treatment fill the house with fruitful wood before the end of the season. If a full crop is wanted the year after planting, supernumeraries should be planted, and these must have the laterals stopped at the first joint, the cane or lead being stopped when 8 or 9 feet long and the laterals allowed a little freedom, but on no account must the foliage be allowed to interfere with or deprive the main leaves of full exposure to light and air. The permanent Vines must be allowed more freedom of lateral growth, the object being to secure a vigorous but at the same time healthy growth with abundance of roots and a few well-developed buds at the bottom of the trellis on well-ripened wood for cutting back to in early winter.

The narrow borders, whether inside or outside, should be mulched with short manure, kept moist to induce the roots to run along the surface, as if the surface be dry they will strike down to the drainage in quest of moisture. The object should be to get surface roots and keep as many there as possible, so as to insure the thorough occupation of the compost with roots, for notwithstanding every effort the roots will get down, and the Vines exhibit a maximum of healthy vigour when the roots appear in mat-like profusion at and among the drainage. This usually takes place in the second year, though the results are not seen in the crop until the third, and which continues up to the eighth or longer, as the means adopted insure a continuance of surface roots passing through the compost to the drainage. Once lose the surface roots and the under roots will soon become less and fibreless, the Vines will show it in the cropping, and without awaiting further indications of coming disaster, prompt steps should be taken by carefully lifting the roots and laying them in fresh compost near the surface. The effect of fresh loam on Vines is magical, especially when sprinkled with bone meal, so that the decay of the vegetable matter of the loam is hastened.—G. ABBEY.

THE ROYAL HORTICULTURAL SOCIETY'S SCHEDULE of prizes and arrangements for the present year is just to hand. The dates fixed for the respective Shows to be held in the conservatory at South Kensington being as follows:—Promenade Shows, March 9th and 23rd, and April 13th; National Auricula Society's Show and Primula Conference, April 20th and 21st; Promenade Shows, April 27th and May 11th; Show of Pot Roses and Azaleas, May 25th; Show of Orchids, June 8th; Show of Pelargoniums, June 22nd; National Rose Society's Show, July 6th; Show of Flowers and Fruit, July 13th; National Carnation and Picotee Society's Show, July 27th; Show of Plants and Flowers, August 10th; Cottagers' Show, August 24th; Show of Grapes and Dahlias, September 7th and 8th; Show of Hardy Fruits, October 12th and 13th; Show of Chrysanthemums and Vegetables, October 26th and 27th. Liberal prizes are offered in the majority of the classes, and numbers of special prizes are contributed by the leading seed firms. The Council have decided to receive provincial horticultural and floral societies into association with the Royal Horticultural Society upon an annual subscription of five guineas. They offer them the following privileges.—The silver Knightian, the ditto Banksian medal, with the bronze Knightian and Banksian medals, to be given as prizes at the shows of the Provincial Society. A member's ticket is issued for the Secretary, and twelve single tickets, admitting the bearer to any one meeting or show of the Royal Horticultural Society.

— THE schedule of the ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL EXHIBITION AT LIVERPOOL is also now issued. The Show will be held, as previously announced, in the Botanic Garden and Wavertree Park, from Tuesday, June 29th, to Monday, July 5th, this year, and prizes amounting to £1200 will be offered in competition. Numerous classes are provided—namely, 135 in the horticultural portion and twenty for cottagers and artisans, in all of which three or four prizes are offered, some being of considerable value. One of the principal classes is for

twelve stove and greenhouse, in which the prizes are £20, £15, and £10, though in two others for nine and six, £10, £7, and £5 are also offered. Orchids are liberally provided for, £20, £15, and £10 being offered for a group of twenty-five, arranged with Ferns, Palms, &c., and in two others the prizes range from £15 to £7. The Liverpool Horticultural Company also offer a cup, value 25 guineas, and 10 guineas in cash for the best twelve Orchids in flower. For a group of miscellaneous plants (300 square feet) the prizes are £12, £8, and £6. In other classes the prizes range from £8 to £7. Cut flowers and table decorations, bouquets, &c., have thirty-two classes devoted to them. Twenty-three classes are devoted to fruit, the prizes ranging from £8 to 10s. Twelve are appropriated to vegetables, including one for "the best collection of garden produce," a novel class which ought to bring out something interesting. Special prizes are also provided by Messrs. James Carter & Co., Sutton and Sons, and Webb & Sons, for vegetables. Medals will be awarded for the best exhibition of examples illustrative of the cultivation of plants, vegetables, &c., on board ship, and silver or bronze medals will be awarded in twenty-one classes for garden implements, structures, &c., together with one or more gold medals for the best general displays.

— AT this exhibition a department will be specially devoted to HORTICULTURAL AND BOTANICAL LITERATURE, SCIENCE, AND ART, which will probably constitute an important and instructive addition to the attractions. Section A is for the literature of gardening, including British and Colonial periodicals, educational books, standard works, foreign garden literature, models, diagrams, and apparatus, and specimens illustrative of grafting and budding. Section B is for technical art, including plans of gardens and structures; and Section C is for botanical and decorative art, comprising drawings, floral designs, photographs, chromo-lithographs, and flower painting on china or terra cotta. Though no prizes are offered, medals will be awarded in the last-named class, and no doubt numbers of amateurs and gardeners will assist in rendering this a representative exhibition. All applications must be addressed to Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, before June 21st.

— ONE of the large plants in the Percival collection of Orchids has just flowered in the nurseries of the Horticultural Company, Garston, and is a very fine form of *LÆLIA ANCEPS ALBA*. This plant was purchased as an imported piece, and is the first time of flowering in this country. The specimen has been divided into several pieces, and one or two plants have been added to collections in the neighbourhood of Liverpool.

— THE date of the OXFORD ROSE SOCIETY'S SHOW has been altered to July 7th, as the 8th would clash with the Bath Show. The alteration is made at the earnest solicitation of a number of exhibitors at both Shows.

— MR. W. BULL, King's Road, Chelsea, sends us some fine PRIMULA BLOOMS of excellent substance, good form, and varied in colour, from white to rosy crimson, purple and very bright red, a double form named splendens fl.-pl. being remarkable for its richness of colour.

— IN the House of Commons on Thursday last, the 11th inst., a vote of £112,619 was proposed for the ROYAL PARKS AND GARDENS but on the motion of Mr. Labouchere this was reduced by £50,403. There were not 150 members present, and the motion was only carried by a small majority, which cannot be supposed to represent the opinion of the House or the desire of the country. It is not likely that this extraordinary and ill-judged proceeding will be carried out, and we expect that the matter will be settled satisfactorily by the adoption of the original estimate. There is no part of the public revenue better applied than the comparatively small amount employed in the maintenance of the parks, and it is the last that needs the attention of would-be economists.

— M. CHARLES DE BOSSCHERE has issued a pamphlet of sixteen pages, giving an interesting description of M. ED. PYNAERT-VAN GEERT'S NURSERY IN GHENT at the time it was visited by the International Botanical and Horticultural Congress in August, 1885; an account of the foundation of the nursery, its subsequent progress, its principal features, and the most remarkable plants grown there now. A woodcut view of the nursery is also given.

— ON several different occasions it has been observed how well Messrs. R. P. Ker & Sons cultivate the CYCLAMENS IN THEIR AIGBURTH NURSERY. At the present time there are thousands of small plants growing in 2-inch pots, the earliest with three or four small dwarf leaves

and the remainder with one and two each. They are grown moderately warm in a light position to keep them dwarf and compact. The earliest of these will be repotted, until they are placed into 6 and 7-inch pots, and will by autumn be from 1 foot to 16 inches through. Such was their condition last year, and many of the plants carried from fifty to a hundred flowers each. To attain the best success the plants must be raised annually from seed, and kept growing the whole season without a check.

— IN the same nursery CROTON NEUMANNI is also conspicuous with its bold highly coloured foliage. It was raised from seed of that well-known variety, Baron James de Rothschild, but has larger foliage than its parent, and the crimson colour is deeper and more vivid. Its habit of growth is well suited either for upright specimens or for large bushes.

— MESSRS. WEBBER & CO. of Covent Garden have recently received a CONSIGNMENT OF PEARS FROM THE CAPE OF GOOD HOPE, consisting of Louise Bonne of Jersey and a variety which resembles Beurré Superfin. They are in perfect condition, and are in appearance equal to well-grown English fruit. We have had an opportunity of tasting the variety supposed to be Beurré Superfin, but the flavour is more like that of Beurré d'Arenberg, having all the briskness of that variety and none of the richness of flavour of Beurré Superfin. If this new importation proves successful—and there is no reason to suppose it will not—the season of dessert Pears will be prolonged far beyond what we have been accustomed to, and the short voyage from the Cape will insure their coming in good condition.

— AN East Lothian correspondent writes—"I once before sent you a note about the time for SOWING BEETS, some of the finest being thrust aside on account of size and coarseness, when the fault is found in sowing too early. Sorts of the Dell's Crimson type may be sown in April, Cattell's Crimson in May, and Veitch's Black about the middle of June, Goldie's should be sown at the same time as the latter. The two last named are fit only for cows if sown in April, earlier than the time mentioned, but sown late they are both really fine varieties, and good strain of the darkest colour."

— THE usual monthly dinner and conversazione of the HORTICULTURAL CLUB took place on Tuesday the 9th inst. The conversazione was opened by an interesting paper of Mr. Shirley Hibberd on the preservation of the British flora. A discussion afterwards took place in which Dr. Hogg; Mr. J. G. Baker, Kew; Mr. Nicholson, Kew; Messrs. Cousens, Drury, G. Bunyard, and others joined. At the close the following resolution was proposed and unanimously adopted, Mr. Shirley Hibberd remarking that great changes had been wrought from much smaller comments, and hoping that this would result in great good to our British flora—Resolved: "That this Club, deploring the extinction in many localities of British plants and Ferns, which tend so much to the beauty and enjoyment of the country, hereby undertakes to use its best endeavours to prevent this destruction, and especially invites all tourists to discontinue the practice of bringing away specimens from the places they visit, which in ninety-nine cases out of a hundred never live, and which can most probably be purchased at a nursery close to their own doors; and urges also on all professional collectors great care in obtaining plants, and, moreover, desires to impress upon managers of provincial shows the need of limiting the collections for prizes for wild flowers, which, they fear, tends to the wonton destruction of many plants."

— MR. G. R. ALLIS grows HELIOTROPE WHITE LADY remarkably well at Old Warden Park. The plants now bearing their large trusses of nearly white flowers were propagated from cuttings in August last, stopped about twice, and then placed into 5-inch pots, the size they are now flowering in. The plants have been brought into flower by the aid of warmth, and are beautiful decorative plants for flowering at this season of the year. These charming plants have six or seven main shoots upon them, with as many large trusses of flowers, and are only 9 inches to 1 foot in height. This is probably the best Heliotrope for winter and spring flowering.

— AN experiment on HASTENING GERMINATION is related by an American writer as follows:—"Last spring I had some Gourd seeds which I wished to sow, but which were mislaid until some time in June. As Gourd seed should be sown very early to allow time for the hard shells to soften, I concluded it was too late to sow them in the usual way, and could devise no better mode of atoning for lost time than by carefully

splitting their shells with a sharp knife and planting the germs without delay. In a very short time the plants appeared above ground, grew vigorously until frost came, and produced the only full and satisfactory crop of Gourds I ever raised."

— MR. ALFRED SLAUGHTER has sent us a sample of his ROSE TUBE. It is a tube within a tube, affixed to a base that enables it to stand in or out of boxes; in fact it somewhat resembles a small candlestick, and will no doubt answer well the purpose for which it is intended—exhibiting blooms of Roses.

— THE annual dinner of the SHEFFIELD FLORAL AND HORTICULTURAL SOCIETY was held March 9th at Mrs. Webster's Museum, Orchard Street. About fifty persons sat down to an excellent repast. After the tables had been cleared the chair was taken by Mr. T. Baker, who was supported by Messrs. T. B. Hague, W. W. Renton, C. Storey, H. Broomhead, G. Seagreave, J. G. Newsum, J. Spink, H. Morton, B. Newham, W. K. Woodcock, sen., and W. K. Woodcock, jun. (Secretaries). The following attended as delegates from other societies:—Mr. Heming and Mr. T. H. Wood (Leeds), Mr. G. W. Simpson and Mr. G. Wassell (Wakefield), Mr. W. Lockwood and Mr. Hall (Barnsley), Mr. Middleton and Mr. Taylor (Rotherham), Mr. W. H. Barnes and Mr. J. Shipman (Walkley), and Mr. C. Cook and Mr. J. Johnson (Sheffield and Hallamshire Gardeners' Mutual Improvement Society). The usual loyal toasts having been duly honoured, the Secretary (Mr. W. K. Woodcock, jun.) read letters of apology from Sir H. E. Watson (President of the Society), the Right Hon. A. J. Mundella, M.P., Mr. C. B. S. Wortley, M.P., Mr. Howard Vincent, M.P., and others. Mr. C. Heming (Leeds) in proposing "The Sheffield Floral and Horticultural Society," said societies such as that were productive of much good to all engaged in horticulture. They, in Leeds, were about forming a similar society, and hoped it would be attended with as good results as had the Sheffield Floral and Horticultural Society. Mr. John Haigh, in responding, spoke in gratifying terms of the benefit which the gardeners in the neighbourhood, both professional and amateur, had received from the Society. The Committee had no wish to make money out of it, but the funds were most economically managed, and no unnecessary expense was undertaken. In conclusion he remarked that the more good the Society could do the more gratifying it was to the members. Mr. W. K. Woodcock proposed "The Visitors and Kindred Societies," and in doing so spoke of the amity and good fellowship existing between almost all the floral and horticultural societies in the country.

— AT the ordinary meeting of the HUDDERSFIELD PAXTON SOCIETY on Saturday, March 13th, the President, G. W. Rhodes, Esq., in the chair, supported by Geo. Jarman, Esq., Vice-President, the members and friends spent a very pleasant evening. Mr. Jas. Inman of Leeds gave an admirable paper on "The General Principles of Gardening," and he did full justice to the subject. Mr. Inman proceeded to describe the proper position of the mansion, the laying out of the pleasure grounds for effect, the formation of lawns, shrubberies, geometrical garden, rosery, and conservatory, with the arrangement, decoration, and general management of the above, which he thought should occupy an easily accessible position in some part of the pleasure grounds unless attached to the dwelling house. The fruit and vegetable garden was next entered upon; soil, situation, quantity of seeds, varieties, rotation of cropping was commented on, strongly advising young gardeners to pay as much attention to this part of the profession as the glass departments; also the various methods of branch and root pruning to promote vigorous, healthy, and fruitful trees was most minutely described. The occupants of the stove, greenhouse, and forcing pits were also alluded to. Those present showed their appreciation of the essay by earnest attention, and by the hearty way they supported the vote of thanks to the essayist. The next lecture will take place on March 27th—subject "A Trip to Norway, with Notices of its Flora," by the President.

— MR. T. W. GIRDLESTONE sends us samples of the NATIONAL ROSE SOCIETY'S NEW MEDALS, and remarks that "The larger medal is struck from the dies designed to provide the silver and bronze medals, and you will notice that it is larger than the former medal, the design now consisting of a shield bearing the monogram of the Society, surmounted by the Rose, Shamrock, and Thistle, and surrounded by Roses of various types—Single Moss, Tea, and Show, with scroll and motto beneath—'Floreat Regina Florum.' The smaller medal, struck from the dies destined to furnish the gold medal, is more conventional in design—the shield bearing a Tudor Rose, with the initials of the Society in Tudor

capitals above, and scroll, motto, &c., beneath." The dies have been admirably executed by Mr. John Pinches, Oxenden Street, S.W., and are exceedingly tasteful in design. Such medals will indeed be worth winning.

### GARDEN ENEMIES.

MANY country gardeners are greatly plagued by the unremitting attention of the various members of the animal world which pick up a living in the vicinity of his charge, and which endeavour on all occasions to lay the products of his garden under contribution for their support. In addition to such garden frequenters as rats, mice, sparrows, and blackbirds, the gardener whose lot is cast in a strictly rural district may have also hares, rabbits, squirrels, pigeons, pheasants, partridges, and peacocks, besides a floating population of the smaller birds ready to help themselves as occasion may offer to any luxury that may be in season. It is just possible that by a little indiscretion in the treatment of those animals which are kept for sport, a gardener may do himself much harm with his master; for it must be remembered that proprietors of estates mostly place a far greater value on hares, rabbits, and pheasants than they do on their gardens, and if the gardener, judging from his point of view that it would be for his master's interest to be less careful of the life of any of these than of the vegetables, flowers, or shrubs under his charge, then most likely he would find there were more points from which the matter could be viewed than his own. Perhaps no one has been more bothered with these "vermin"—shall they be called?—than I have; but there has always been the consoling thought that neither the destroyers nor the destroyed were mine, and if it pleased their owner to allow things to remain so, there was no reason for heartbreak on that account. However, it has been my endeavour to lessen the mischief as much as possible, and hence these notes, which it is hoped may be of use to others placed in similar circumstances.

It is a somewhat curious fact, that either birds or animals which are allowed to feed on any given crop—and this applies to shrubs and other things—are most difficult to break of their habit. We have had certain crops which pheasants never touched for years, yet on being driven to these by lack of food they have ever since continued to attack them. Again, if blackbirds once attack Strawberries or other fruits, no matter how plentiful other food may by-and-by become, they pass it, while in seasons when their natural food is plentiful they do not attack fruit so much. Bearing this fact in mind, it will prove good policy to keep all these depredators away as long as possible. I have also found that both birds and game can be boycotted so effectually as to cause them to leave their old haunts altogether. But in order to insure an effectual cure the means taken must be effectual. As an instance, say a garden is overrun by pheasants, which make it feeding ground, breeding place, and, in fact, their home. In order to get rid of the whole tribe it will at once be seen that no half measures will do. Of course such pheasants are quite tame, and any attempt at frightening them off end in ignominious failure, the birds meanwhile showing by their behaviour that they are quite incapable of grasping the meaning of such a course of procedure towards them. The flowers and vegetables which pheasants are particularly fond of, of the former, Ranunculus, Crocuses, Anemones, and occasionally Lobelias and Sweet Peas in a very young state; of vegetables, Peas, Beans, the Cabbage family, and sometimes Lettuces; the young shoots of Asparagus and newly planted Artichokes are also laid under contribution sometimes. In order to disperse a colony of pheasants it is necessary that any of the products above named which they are in the habit of attacking should be thoroughly protected. This entails the netting of Peas and Beans from the time they are sown until they begin to flower, and if any of the others are meddled with they must also be netted. Coarse-meshed wire netting, rounded, and pegged down over the rows of Peas protect them until they are ready for staking, after that herring nets are required. Herring nets are also most suitable for other crops, only great care is necessary in seeing that the nets are so secured as to keep the birds out, as if they get in and get entangled in the nets the likelihood is that such netting will be put a stop to. A good way to save Ranunculus and Anemones is to grow them in beds covered with coarse wire netting. In large kitchen gardens it is next to impossible to keep hen pheasants from breeding. The only remedy is to send all eggs as found to the keeper, and in cases where young birds are brought out to get mother and brood removed without delay. Provided the above care be taken to net everything that the birds attack, and they are not allowed to feed in the garden, then it remains for them to move to other quarters. Where pigeons are troublesome the only certain remedy is to shoot the first comers, for if they are

allowed to feed for a time they are not easily kept down. The destruction of every nest in the vicinity of the garden is also very necessary.

With regard to hares and rabbits, it may be pointed out that much of the wire netting that is put up to keep these from shrubs, or out of gardens, &c., is of very little use for that purpose. It fails in three respects—in the mesh being too large, in the wire being too weak, and in the width being often too narrow. The size of mesh ought to be not more than  $1\frac{1}{2}$  inch, seventeen gauge being not a whit too strong, and where hares abound they cannot be kept off shrubs during hard weather if a less width than 30 inches is employed. This gives quite 24 inches above ground after a portion of the netting has been turned in and buried to keep rabbits from burrowing underneath.

There are numbers of dressing materials employed for keeping hares and rabbits from barking the stems of trees, but it is doubtful if a more efficient or a more lasting dressing is to be had than clay worked up with cowdung to the consistency of paint, and put on with a brush. We have found this a most excellent dressing. Tar is sometimes added, but we have not found it necessary to do so, the clay itself being sufficient to keep the animals from biting, while the dung makes it adhere for a long period. Squirrels require to be handled in exactly the same way as pigeons. Kill the first comers, for if allowed to feed unmolested for a while every squirrel in the district will come to learn of the boundless supply, and arrive for his share in company with wife and family. Squirrels are not easy to keep off wall trees; the only practical plan, if herring nets are used, is to keep them well out from the walls by means of forked sticks, using the nets doubled, and pegging the nets down on the fruit borders. Hexagon netting is of much greater value than herring nets, and with a little attention to watching squirrels can be kept from the more select fruits by means of this material.

I might add something about my experience with the smaller birds, which are here as sacred as game, something about rats, mice, wasps, &c., but would only add that the same remark applies to these as to the subjects proper of these notes—viz., that prompt measures, or even in some cases defensive measures taken before attack, is the only road to victory.—A COUNTRY GARDENER.

### ARALIA CHABRIERI.

MANY Aralias are now becoming favourites for decorative purposes, especially for tables, as the best of them are light elegant plants admirably adapted for this purpose. Aralia Chabrieri is gradually making progress amongst the favourites of this class, one great recommendation being its free growth. It is easily cultivated in pots of moderate size, and a compost of peat and light loam, the temperature of a stove being most suitable during the growth of the plant's, but afterwards they will endure a much lower temperature for some time without injury.

In the woodcut (fig. 40), kindly lent by Mr. B. S. Williams, who grows the plant remarkably well, the chief characters are well shown, he also refers to it as follows:—"A charming plant, with graceful pinnate spreading leaves, admirably adapted for table decoration. It is of medium growth, leaves alternate, in well-developed specimens about a foot in length; leaflets opposite, from 6 to 9 inches in length, linear lanceolate, deep green with a heavy crimson midrib, which gives the plant a Terminalia-like aspect." It has been awarded certificates at all the principal horticultural exhibitions in Great Britain during the past two or three years.

### HINTS ON ORCHID CULTURE.

(Continued from page 189.)

#### CULTURAL OPERATIONS.

POTTING AND BASKETING.—In all operations connected with Orchids it must be remembered that the roots cannot be safely treated like those of many plants in general cultivation; they are much more delicate and readily injured, consequently in potting or basketing much care is needed. If the old roots are adhering to the sides of the pots or the drainage, the pots must be broken, and these, or the pieces of crocks, placed in the new pots, disturbing the roots as little as possible. All dead roots must, however, be cut away, and if any of the others appear unhealthy, or if the compost was old or much decayed, they should be washed in tepid water. When it is desired to transfer a plant from a small basket to a larger one, and the roots are much interlaced amongst and adhering to the bars, as is often the case with epiphytal species, it is usually a safer plan to employ a basket of sufficient size to allow the old one being placed in it, filling

the intervening space with the compost. Pots should be thoroughly drained, the largest having smaller sized ones inverted in them, and the space round these filled with clean potsherds, or these can be used alone. For all large specimen epiphytal Orchids the drainage should be two-thirds the depth of the pot; for terrestrial Orchids less will be required according to the strength of the individual plant and the character of the species. Large pieces of potsherds are arranged hollow side downwards, but charcoal, or rough burnt clay, such as is termed ballast, can be used for the same purpose. Over this place a layer of sphagnum, and then put the plant in position, filling with the compost which may have been either previously mixed, or the peat, &c., can be introduced separately, firming it amongst the roots sufficiently to hold the plant steady, but not pressing it down as is practised with other plants. In the case of large heavy Cattleyas, Lælias, &c., it is sometimes needful to employ a few pegs, or a stake, to assist in holding them steady until established. It is advisable in most cases to raise the base of pseudo-bulbous Orchids slightly above

One reason for this is probably due to the fact that in baskets they do not suffer quite so quickly in hot weather, whereas blocks need very frequent attention in watering during the summer, or the plants may be injured beyond recovery. When an Orchid is to be grown on a block a little moss may be placed round the base of the plant, and the latter firmly fixed by a few pieces of copper wire passed across and nailed to the side or back of the block. In some cases the moss is not requisite, but it is safer for beginners to employ a little at first.

The time at which these operations require to be performed varies, for in their native countries Orchids commence their growth at very different periods; but it may be taken as a general rule that as soon as root or leaf growth is commencing potting or basketing can be safely done. In many species the commencement of activity is readily seen in the protrusion of young roots at the base of the stem or pseudo-bulb, and in others new growths will be seen pushing from the lower portion of the plant. The adoption of lower winter tem-

Fig. 40.—ARALIA CHABRIERI.

the rim of the pots, making an even rounded surface of peat, covering this with the selected sphagnum previously mentioned. Some have tried other native mosses, such as are usually found in abundance in woods or shady places, for this purpose, and in the cool houses they succeed well, having a pretty and more diversified appearance than the sphagnum; such material, however, needs very careful examination, or many destructive insects may be introduced with it. For a number of the more delicate epiphytal Orchids grown in baskets, potsherds, charcoal, or a few lumps of peat are sufficient, or the two former alone, rather loosely arranged, especially for species of the Stanhopea and Acineta type, which force out their flower spikes from the base in a downward direction. Orchids grown in the small shallow perforated pots already noted require scarcely anything but peat and a surfacing of moss. Blocks are not so frequently employed now as formerly, but there are some plants, like Cattleya citrina for instance, which from the nature of their growth are much better on blocks than in pots or baskets; but there are comparatively few strong-growing species which cannot be more satisfactorily grown in baskets.

peratures necessitates resting most Orchids which need that treatment in the duller months of the year, consequently growth generally commences in February and March, when the majority can be safely potted. But the rule previously given can be followed as regards those that start at other times; but for such as are growing to some extent all the year, like Odontoglossums, the potting season may be regulated according to convenience, and Orchids of the Vanda and Aerides type may be so treated whenever they are not in active growth, but preferably just before they start, and the early spring will be found the most satisfactory time for the majority. Some Orchids require repotting or basketing much more frequently than others, the strong, quick-growing species needing attention every year; the slower, more delicate sorts often thrive well enough for several seasons with only an occasional renewal of the surfacing. The latter should, however, be looked to every year, as it improves the appearance of the plants very much, and is beneficial to the young roots, which dislike old decayed materials about them.—AN AMATEUR.

(To be continued.)

## THOUGHTS ON CURRENT TOPICS.

THE subject of lime and its application is still under discussion. It is an important subject, on which a diversity of opinion appears to exist. An able correspondent, "A. L. G.," is evidently content to apply this mineral in homoeopathic doses. He may be right as regards the soil he has to deal with, but I am strongly convinced that there are hundreds of gardens that have been heavily manured for years, and hundreds of enriched Vine borders that would be quickly and permanently improved by generous applications of lime—indeed, as a rule a light dusting of lime has no marked effect on Vines and other crops in rich soil. Your correspondent is, in a measure, supported in his views by Dr. Caldwell (page 131), who quotes the old saying that lime applied to land tends to "make the father rich and son poor." But does not that depend on the son? Twenty-six years ago next April I was requested to make a large and then worthless plot of very strong land produce something. It had been deeply trenched, and the site had been previously an enclosure for cattle—a huge crew yard. More lime was applied than I have yet seen advocated in this Journal, and certainly the produce from the ground the same year greatly exceeded the aggregate total of the five years previously. The lime was more than paid for the first year by the enormous yield of Potatoes, and in one particular part where it was applied lavishly, as a little experiment, the crop was remarkable. This was an example of making the "father rich." I have quite recently been to see how far the heavy liming had made the "son poor." I found the land in splendid condition, and I suspect not many more productive plots could be found. In this case, which is not the one I previously referred to, the truth of another saying was revealed—"Lime is the basis of good husbandry."

YOUR correspondent, I think, attaches too much importance to the escape of ammonia into the air, consequent on the action of lime. His experiment of dissolving sulphate of ammonia and lime in water does not prove any such escape from the soil, but only from water, which is quite another thing. Ammonia liberated by lime is absorbed by soil of a loamy character—that is, containing clay, without which it is not loam. Ammonia is also absorbed and retained by humus, or black rich soil. This may be ascertained by mixing sulphate of ammonia in water and passing it through a large potful of either firm damp loam or soil rich in humus. The sulphuric acid, which is of little or no value, will pass through, but the ammonia will be left behind. It will not, however, be retained by a potful of sand. So far, then, from the ammonia which is sealed up in over-rich soil being lost by liberation, it is a distinct gain. This I have found true in practice, and over-manured Vines, Roses, and land generally have been greatly improved by liberal applications of lime.

IF any reader of these notes has a bed of Roses in which the soil is almost a black soapy mass by repeated applications of manure, and yet the Roses are not satisfactory, but the leaves thin in texture and pale in colour, as many are under those circumstances, let him slake some lime, spread it half an inch thick on the surface, and lightly point it in as soon as the ground is in suitable condition. The Roses will improve forthwith, and will be better still another year; and so will Vines under similar conditions, and the border dressed in the same way. I found some Rose beds in the condition indicated in 1860, the plants lingering in a mass of humus. They were limed as stated, lighter dressings being given annually for seven years subsequently, and I have no doubt the practice was continued afterwards. I found the Roses sickly and left them vigorous. The beds continue, with many of the original plants, to this day, the son of the former owner having enjoyed them for years. Newly made Vine borders, unless limeless, do not require liming, nor is poor soil generally improved by applications of lime alone. This, at least, is my experience, and what I have recorded is solely with the object of affording guidance to others, and not for opposing the views of a correspondent who is evidently an earnest searcher for truth, and thus entitled to great respect.

PROFESSOR CALDWELL'S articles on manures contain much "food for thought." He lays stress on the value of farmyard manure mainly as conveying humus to the soil. When this manure is alone used in large quantities year after year the accumulation of humus neutralises the effect of other fertilising constituents. Humus is of great value, no doubt, especially in poor soils and dry seasons, as a vehicle, so to speak, for containing real plant food that can be applied in a concentrated form. The bulk of farmyard manure is not plant food, and if coloured liquid is allowed to drain from it its spirit departs—the shell remains, but the kernel is gone. Such a mass to be of any service must be supplemented with nitrogen, phosphorus, and potash mainly. When we consider that 2 lbs. of sulphate of ammonia contains as much nitrogen as does 100 lbs. of farm manure, and that the same bulk only contains the same quantity of phosphates and often no potash, when the drainings escape, it is easy to perceive that much good may be done by using what are known as "artificial," such as bonemeal, kainite, and sulphate of ammonia either apart from or in addition to farm manure. To give sufficient of what plants and crops really need in the form of natural manure a great deal more of this has to be used than is in other respects good for them; in fact, in rich gardens the bulk is often injurious; and in instances innumerable it would be far better and cheaper to purchase a mixture containing a good proportion of ammonia, phosphates, and potash than to

invest in farmyard refuse with the spirit gone. "For those three substances," says the Professor, "any arable soil that is not too sandy is a most trustworthy savings bank." No doubt that is so, and in such soil they may be used with certainty of doing much good without any stable manure. In sandy soil they are of great value with manure to afford humus. This, too, as has been incidentally mentioned, may be afforded by green manuring—a practice that is not sufficiently adopted, especially in light sandy land.

AFTER no inconsiderable experience in working sandy soil in a dry district I have arrived at the conclusion that no method of procedure is worse than to turn it up in the autumn. Digging and adding manure then is positively wasteful. Far better is it to sow Rape, Minstard, Turnips—anything, as soon as possible in the autumn for covering the ground and dig them in in early spring, planting and sowing so far as may be convenient as the work proceeds, adding fertilisers at the same time, to be supplemented as might be required with nitrate of soda when the crops are above ground. In this way the nutriment can be appropriated, applied to porous soil in autumn, and the land dug. Half, and often more than half, of the virtues are washed away by the rains and melting snows of winter. If I had a sandy garden I would allow no man to wheel on manure and dig the ground until spring if he wanted to do the work for nothing. Such land should be dug in early spring before dry weather sets in, and be made firm by treading before sowing or planting, afterwards maintaining a loose surface by the use of the hoe.

IT is not much use arguing with Mr. Hiam on the cause of canker in fruit trees. He appears to labour under the delusion that no one but himself and Mr. Harrison Weir have examined specimens with the aid of a microscope. The last-named gentleman is not only a microscopist, but a naturalist and expert draughtsman. It could not be difficult for him to accurately figure the "mites" much enlarged, and entomologists who have given special attention to minute animalculæ would be able to throw much light on the subject; and if it should be determined that insects are really the cause of canker in fruit trees generally, Mr. Weir would deserve the thanks of the fruit-growing community. In the meantime, I can assure Mr. Hiam that methylated spirit, petroleum and Gishurst compound have been applied thoroughly, repeatedly, and systematically until the "American blight" has been totally eradicated, but canker has neither been cured nor prevented. I have been to a district where all the Apple trees are cankered that have been planted a few years. There is no exception as to varieties. Young trees grow in the most satisfactory manner until the roots reach the marl, then the evil shows itself. If insects are the cause it is singular they should come at that particular time. A choice and much-prized collection, belonging to one of the foremost horticulturists in the kingdom and a gentleman of great scientific attainments, is in the condition described. The microscope reveals no mites, though they have been most carefully sought for, and he would only be too pleased if he could find satisfactory evidence of the truth of the insect theory. So far he is quite unable to do so, but there is no possibility of ignoring the presence of canker when the roots of the trees reach the marl. Till then they are free. That is a fact as cogent in its way as any facts that can be adduced in favour of insects eating Mr. Hiam's trees.

AS sure as spring comes round so do inquiries about and estimates of the merits of Peas. I have tried nearly all the varieties in commerce, and shall continue growing new sorts as long as opportunity is afforded. There is much pleasure in small trials, and when seed is saved of the best varieties, no loss; but varieties of proved merit are alone relied on for giving a regular supply of Peas for use, those "on trial" not being taken into account for this purpose. It is to be remembered that varieties do not grow and bear equally well in differing soil. I have practised in a garden where Veitch's Perfection was one of the best to rely on; in another it could not be depended on. With Dr. Hogg, Champion of England (or Huntingdonian), and Ne Plus Ultra, I can insure an unbroken supply of first-rate Peas over a period of six months; so I could with William I., Telephone, Duke of Albany, Veitch's Perfection, and Omega, soil being favourable; or again with American Wonder, Advancer, G. F. Wilson, House's Marrow, and British Queen. Other gardeners can, no doubt, succeed equally well with other varieties. If I were condemned to grow two varieties only they would be Dr. Hogg and Ne Plus Ultra, and with these there would be no break in the supply, and no complaints as to quality.

MR. GIRDLESTONE'S truly admirable articles on single Roses have doubtless been perused with interest by many readers. It is difficult to repress a feeling of envy in respect to the literary accomplishments of the author of them. In that respect knights of the spade must be content to follow at a respectful distance, but they can, and do, impart useful information in an agreeable manner. My contribution on the subject of single Roses shall be confined to one species—the delightful Sweet Briar. This should be grown in bushes for forcing in pots for supplying greenery for flower vases from the present time onwards; also in larger bushes in shrubberies, or as divisional hedges in appropriate positions. I wonder if it is generally known that the simplest, easiest, and cheapest method of raising a number of healthy plants is to sow seed in drills in the open garden in spring. A gardener who has raised a great number finds them more vigorous than plants from cuttings, and that every one is true to character. Some of these I have seen. Possibly this method of increase

may be known to some readers. I do not remember having seen it recorded.

My kindly critic, "A Wisher," &c., who says he is not a farmer, but proves that he is one, and a gardener to boot, appears to fancy I have been overthinking myself. Possibly he may be right. It is a question of fact, however, that English Apples well grown are quite equal to American fruit in value; another fact being that tons are produced in this country that can hardly be sold. It is a question of selection and culture more than anything else, and American growers wonder that we are so kind as to afford them such a market. With a good choice of sorts and better culture plenty of Apples can be grown in this country, and, well marketed, will meet with a ready sale. We are just jogging along on the old lines and permitting our more enterprising competitors to glide past us, that is all. It is a mistake to send small colourless Apples from the north to Covent Garden, because better samples are grown in the south. It answers to send Celery and Turnips from the north to London, because they are better than those grown in the south. That is the simple explanation, and there is a slight difference between those crops and Apples. A northern friend of mine planted an orchard twenty years ago, and it paid him so well that he has recently planted another, but he knows better than to send his fruit to Covent Garden. He could send a thousand tons of Turnips to London if he chose next week, but as he has a thousand sheep he will probably not do so. He can, and does, make farming pay well; so can any competent man with sufficient skill and capital, under a rental of 25s. an acre for land that is capable of producing 5 quarters of Wheat. That was my assertion. The constant clamour for still lower rents, and waiting for more abatements, are ruining British agriculture, waiting for grants meaning neglect in culture and management. I am reminded of the hours of labour on farms. Let me assure "Wisher," &c., I know all about them, have done all he suggests, and could tell him, if needed, how he spent his afternoons. He was in error in implying I had not spent "one year" on a farm. It is "never safe to prophesy unless you know."

"UTILITARIAN" also appears to be a farmer as well as a gardener, so there are three of us. It is clear he knows the evil and the remedy. "Treat the land fairly," he says, "and it will pay good interest on investments." He is right. I am intimately acquainted with much land that has been doing so all through the "depression." I daresay I shall shock some tenderly constituted individuals when I state that in my opinion "depression" in thousands of cases, not in all, is only another name for wasted means and bad farming. By the way, I have one or two items of news for your correspondent. Since the discussion on gentlemen competing with market gardeners two of the former have relinquished the practice, one because he thought it was "not right," the other because he was "no better off" by marketing. There may be more, but those two cases have been made known to me. I have farther been told on good authority that a gentleman has prohibited premiums being paid by young gardeners in part payment of his own gardeners' wages, which he has increased in proportion. I should like to ask for three genuine gardeners' cheers for this considerate and just man. Deeply conscious of my own failings, I rest in the hope that not much more harm than good has been done by the random notes of—A THINKER.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 195.)

### POMPONS FOR LARGE BLOOMS AND BUSHES.

POMPON and Anemone Pompon varieties of Chrysanthemums are particularly adapted for amateurs whose space is often of a limited nature. They can be grown quite dwarf, and their freedom in flowering renders them specially useful for cutting. Opinions differ as to the manner in which the cut flowers should be staged for exhibition—whether in bunches of three blooms, one on each spike, supported 3 or 4 inches above the stand to show the foliage, or in bunches comprising an undefined number of flowers without any disbudding. The former I regard as the more satisfactory, for under what is termed the "big bloom method" the real character of the variety is brought out both in size, form, and colour. The foliage too is much better, which enhances their appearance; and in staging for exhibition a much more uniform stand can be obtained than by irregular-sized bunches. It is much easier also for judges to determine the merits or demerits of a stand when an equal number of blooms are staged in all stands.

Where the plants are grown solely for home decoration, and quantity of flowers is the chief object, the bush method of cultivation is the one to be adopted. To grow the plants for the production of large blooms for exhibition the cuttings should be inserted in single pots towards the end of December, shifting and transferring to frames as required. Do not top the plants, but allow them to grow till the first break occurs, when four or five of the strongest branches should be selected, removing the others, also all shoots as fast as they appear from the main stems. Should a second break occur by the formation of a flower bud early in August, the bud and the shoots must be again taken off, retaining only those branches which were selected at the first break. If the

break occurs during the last days of August rub out the shoots then made and retain the flower bud formed at the end of each branch. These will produce large blooms if all other details are properly carried out. Pots 8 inches in diameter are quite large enough for Pompoms, the soil and manner of potting to be the same as for the other sections. House the plants from five to six weeks prior to the time they are required to be in bloom, placing them in a light position as near the glass as possible.

There are two methods of growing Pompoms as bush plants—tall and dwarf. Where suitable places are available I prefer plants 4 and 5 feet high, as their long branches of flowers are much handsomer than those on dwarf plants, which are, however, valuable for low houses and special positions and purposes. The middle of January is soon enough to take the cuttings. As soon as the plants are 4 inches high top them, and from this topping several other shoots will spring. Those that are intended to be tall plants should have three of the strongest branches selected, which should be allowed to extend, retaining all side shoots. Do not top them again. Buds will form in September, and all may remain to flower. For producing dwarf plants top when the shoots are 4 inches long, and continue the practice till the first week in July. Secure the growths to prevent breakage by wind, and when the flower buds are formed at the end of September tie out the branches according to requirements and consideration of the position the plants are intended to occupy when in bloom.

### NATURAL-GROWN PLANTS.

In a treatise in which I hope to touch on all matters connected with Chrysanthemum culture I should like to express my opinion on so-called natural-grown plants, not with a view of encouraging their growth, but simply to define what is really a natural-grown plant. The term is, I fancy, applied in many instances in a wrong way. What I consider natural-grown plants are those grown from cuttings, never topped, the shoots not thinned, nor any flower buds taken off. I do not think anyone would care to grow Chrysanthemums in that way if they knew what would be the results. The plants would range in height from 2 to 10 feet according to the varieties and seasons; the blooms borne at the top would be small, many hollow-eyed and almost unrecognisable if compared with good flowers of the same varieties. If any person wishes to grow them in the way indicated, strike the cuttings any time during January, treating the plants in the usual way as to potting and watering, and when they make their first break in May, instead of thinning the shoots to a few as is necessary in other methods of culture, all should be allowed to grow, continuing this "natural" treatment at the next break also.—E. MOLYNEUX.

(To be continued.)

### HOME-GROWN LILY OF THE VALLEY.

THE belief in the superiority of home-grown Lily of the Valley is gaining ground, and wherever the plants are attended to there can be no mistake in the matter. We can have these Lilies of the Valley in flower earlier, in less heat, with absolute certainty, and with foliage and flowers, while with these advantages the spikes are on the average longer than those from the foreign roots. Lily of the Valley has a peculiarity which I presume it has inherited from its wild progenitor of the woods, and that is a decided liking for partial darkness. The flower spikes can be produced in the light; but in order to have foliage with the flowers, partial darkness is necessary. A covering of straw I have found most suitable to gain this end. But even after the straw has been removed it is sometimes necessary to keep the plants away from the light in order to develop the foliage. This is specially the case with clumps which have been lifted from the open and forced for the first time. The curious thing about it is that plants standing, for instance, under the stage of a stove, do not have the foliage drawn either to one side or the other, but it grows just as upright as if in the full sunshine out of doors. This liking of the plant to shade can be taken advantage of, after the flower spikes are removed, by standing the plants along the sides of pathways, where very few other plants would grow. Lifted clumps produce splendid spikes and foliage if placed on the surface of Vine borders under the shade of the Vines, or under Roses or other climbers. At the same time it must not be forgotten that the finest out-of-door flowers are grown in the open sunshine—at least, we find it so.—B.

### HARBINGERS OF SPRING.

THE present winter, if not one of the most severe of late years, is one of the most prolonged, and as a consequence our earliest plants are very much behind their usual time of flowering. The plants which have dared to raise themselves above the soil are at present few as compared with the end of February last year, when Daffodils were springing up abundantly and Winter Aconites and Snowdrops were numerous everywhere. This season even the Winter Aconite (*Eranthis hyemalis*), though in flower, is much later than usual. This is one of the most brilliant and effective of our earliest flowers. It is a plant suited for naturalising in shady spots beneath trees, or fringing a bed of Rhododendrons, for the margin of a

bed of American plants, on sloping banks—anywhere, in fact, will its bright golden flowers produce a striking effect in the dawn of spring. If allowed to remain unmolested for a few years it will form a dense mass, and, like the Snowdrop which bears it company, will thrive in almost any barren spot, where even grass fails to find food sufficient for an existence.

No flower is more charming at this season than *Iris reticulata*, with its fragrant violet and gold flowers; but while it seems to hattle with wind and rain, frost and snow, it is not advisable to expose it to all the damaging influences, therefore I would urge that some protection be given it, such as a cold frame. It may be increased by the offsets of the bulbs and also by seeds, and very interesting is it, in adopting the latter method, to mark the variation of its offspring. It seeds somewhat freely, and those who wish to have a stock of this pleasing plant in their gardens should save all the seeds possible. Years ago the late Mr. Atkins of Painswick was a most successful cultivator of this and many other choice plants, and I well remember a patch several feet square and which contained hundreds of bulbs in flower at the time of my visit. The value of such plants when well established cannot be over-estimated. There are varieties of this *Iris* equally lovely, though rarer, while others are not in commerce; among these being *I. reticulata cyanea* and *I. reticulata purpurea* (Krelagei). The former received a certificate of the first class at the meeting of the Royal Horticultural Society on the 9th ult., and to have it in perfection at such a time and in such a season as the present is in itself sufficient recommendation. I cannot overlook the lovely *I. persica* and *I. stylosa*, the former delicate in colour and possessing a fragrance unsurpassed. The colour is blue blotched with purple, yellow, and white; it is of diminutive growth, only a few inches high, and comes in early February; it may be planted in light, though deep rich sandy soil, in small clumps, either in the herbaceous border, the rockery, or in company with the Netted *Iris* in a cold frame. Whether I am justified in including *I. stylosa* within the limits of these notes I

Fig. 41. —A Curious Cineraria.

know not, for we can hardly refer to it as spring flowering, for during my own experience I have had it in flower from November to April. My experience of this lovely and chaste gem is as a winter flower, at least from established clumps. From those which have recently been removed flowers issue at intervals during the period stated, but come when they may the delicate beauty of its flowers is ever welcome. These are of a pleasing and beautiful light blue with yellow blotches, the flowers issuing from a tuft of leaves in an unexpected manner, which would seem to make them doubly welcome.

We have the trio of Giant Snowdrops in *Galanthus Elwesii*, *G. latifolius*, and *G. plicatus*. These all come in early February, and are so widely distinct from the rest as to merit the name of "giant." In the first we have the best of the large-flowered varieties, and which has been in excellent condition for a month past. The foliage is large, the sepals pure white and much winged in its latter stages, while the bells are white margined with green. All the above are as easily cultivated as the common Snowdrop, and should find a home in all gardens. *G. Elwesii* is fully 10 inches high, and it will even exceed this height when well established.

Turning from the Snowdrops, I will next mention the white Hoop Petticoat Narcissus. *N. monophyllus*, the earliest of its relatives, even with 10° of frost last night, has been flowering in the open, protected only by a light temporarily placed on some brickbats to keep it clear of the flowers. It is a flower of glistening whiteness, of pleasing fragrance, and its height is only 4 to 6 inches, thus making it a charming pot plant for the conservatory. It is not impossible to construct an indoor rockery where such plants as these may be at home, having portable lights, which may be at any time removed. Such a structure would be a boon in a hardy plant garden, giving just the assistance so many plants need—i.e., protection from the change of temperature, drenching rains, and winds, and might well embrace all the best among hardy bulbs, and more especially the first of our spring flowers. Such a structure may be erected at comparatively small cost, and, I may add, be unheated. Later on in the season the other members of the Hoop Petticoat Narciss will be coming

on—e.g., *N. hurbocodium*, with varieties *Grealii citrinus*, a large handsome form, and *conspicuus*, the large golden. Succeeding these we have *N. nanus* and *minor*, and ere these are past the innumerable host of *Narcissus* and *Daffodils* will be making considerable headway, rendering a garden with a fair complement of them most enjoyable.—J. H. E.

### A CURIOUS CINERARIA.

LAST season we had a very curious seedling *Cineraria* sent to us by a friend. Its ray or outer florets were involute (fig. 41) somewhat as are those of double Dahlias. The colour was peculiar, being bright rosy pink, margined with bright crimson. The friend who sent it promised to save seed, but some accident happened to the plant, and so no seed was forthcoming. Why the outer florets should have curled their margins inwards in this fashion is past explanation, but it may serve as an example of the vagaries often observable in plant life, and for which we know no cause. Some plants are remarkable for their variable-shaped florets—to wit, the *Chrysanthemum*. Everyone expects the *Chrysanthemum* to exhibit this variability, but no one, so far as we know, has yet tried to obtain similar results from other composite flowers. There is a variety of the common Ox-eye Daisy which has tubular or quilled ray florets instead of flat ones, and we see no good reason why such varieties of *Cinerarias* should not some day become popular, just as *Betteridge's Quilled Asters* are now. Our illustration is an example of how Nature, the dear old nurse, gets in the thin edge of the wedge when she wants to effect a change. A florist would laugh at a flower of this sort, and tell you that it was like a windmill, or that there was too much daylight to be seen through the florets, but Nature is the greatest florist after all, if we could but understand her reasons as clearly as we see her variations.—F. W. B.

### ARTIFICIAL FERTILISATION OF ROSES.

A LETTER written by the late H. B. Ellwanger, author of "The Rose," in reply to a private correspondent several years ago, appears in the *American Florist*.

"Your letters duly received. This is my first opportunity of answering. *Général Jacqueminot* for many reasons would make an excellent female parent. I have this winter fertilised five or six flowers of this variety, and now have seed pods forming, one fertilised by *Solfaterre*, another by *Safrano*. Roses should be fertilised on a sunny day. Before the flower is fully blown which you intend to fertilise the petals should be carefully pulled off and the stamens then cut off with a fine pair of scissors (embroidery scissors). The pistils are ready for fertilisation at the same time when the stamens are ready to drop their pollen, hence the necessity of cutting off the stamens three or four hours before the pollen ripens; if this is not done you are not at all certain whether any cross has been produced or not. Removing the petals hastens the ripening of the pollen, and without this you could not remove the stamens of many of the full sorts. It is my opinion that the male parent has more potency, as a general rule, than the female, and should advise you to make crosses with this in mind. Thus, from *Safrano* as a male parent and *Général Jacqueminot* as female parent (which cross I have made), I should expect a flower less full than *Jacqueminot*, but which would give a beautiful bud, perhaps a little fuller than *Safrano*. I have made many crosses, using varieties of *Bourbon*, *Bengal*, *Hybrid Perpetual*, *Noisette*, and *Tea*. I have used *Solfaterre* a good deal as a male parent on account of its colour and vigorous growth, though *Safrano* will give twice the amount of pollen. Besides *Général Jacqueminot*, you will find *La Reine* and *Baron de Bonstetten* excellent female parents among the Hybrid Perpetuals. The seed is best gathered late in autumn before any hard frost, the hips placed in sand in pots (covered with glass or something else to protect from mice) and planted in January under glass. Most of them will come up in a few weeks, and when up for a few days can be picked out and potted in small pots.

"I presume *Bennett* makes the *Tea Rose* the female parent because it is the more tender, and the male parent being more potent in its influence he uses for such the Hybrid Perpetuals, which are harder than the *Teas*. The most of them, judging merely from their appearance and breeding, will be as hardy as the *Victor Verdier* type, and perhaps more so. You will find that *Niphetos* will make but an indifferent female parent, and will not be a male parent at all, but in the first way will be worth experimenting with. I am very glad to know that you are interesting yourself in this matter. I have several correspondents now in this country who are taking hold of the productions of seedling Roses from artificial fecundation, and I am positive that among us we will produce many varieties of great value. I hope you will keep me informed of any progress you make."

### NOTES ON PEAS.

I SEE in the *Journal of Horticulture*, March 4th, page 166, "A Kitchen Gardener" makes a few remarks upon growing Peas. He also says that he has had the satisfaction of surpassing one of my best collections at South Kensington, which I have no doubt is true, but your correspondent, I think, makes a mistake when he says he has not had time to grow for exhibition since heating my collection, and then afterwards admits taking a prize with *Wordsley Wonder* at South Kensington in 1884. The year in which he beat my best collection of Peas must have been before 1884, as in that year, and also in 1885, I had the honour of taking all the first prizes at South Kensington when I exhibited.

"A Kitchen Gardener" says he would undertake to sow any kind of Pea on the 14th March, and exhibit it in prime condition the 14th of July. Perhaps he could do so in his district, but he could not do so here without the help of a glass house or frame. This part of Lincolnshire is perfectly flat for more than ten miles around me on three sides, and we are only four and a half miles from the sea on the other, so that we have no hills to shelter us, and are subject to many cold easterly winds direct from the German Ocean. If I wished to exhibit a collection of second early Peas, such as Telephone, Stratagem, Pride of the Market, Telegraph, Wordsley Wonder, House's Perfect Marrow, and Evolution, the last week in June or the first or second day of July, I should sow the seed about the first week in November, and if the following spring was no more favourable to vegetation than the past seven have been the Peas would not be ready any too soon for exhibiting the last day of June. I am writing from several years' experience, so that "A Kitchen Gardener" may see that it not only takes seven months to grow some Peas to perfection, but nearly eight. I may add that I could sow the seed of the above named Peas on the 14th day of May, and have them ready for exhibition by the 14th day of August, which would be about thirteen weeks.—HENRY MARRIOTT.

#### KITCHEN GARDEN.

**THE WEATHER AND WORK.**—Readers who may have thought our previous notes and recommendations were not in accordance with the unusually severe weather experienced of late ought to take into consideration our advice to carry out the work on "every favourable opportunity;" and much as we should like to give an accurate forecast of the weather at the beginning of each fortnight, we have to be contented with recording our practice and recommending operations which ought to have attention, always, of course, with the understanding that the weather is suitable; and when such is not the case, overdue sowing and planting must be accomplished on the first favourable opportunity. Amateurs with nobody but themselves to grow for, and no one to blame them if their crops are late, may not be troubled in late cold springs, but gardeners, and especially those in small places, know how important it is that their supplies be produced as soon as possible. In instructions, however, which appear in this column it can hardly be expected that the operations should be practised on the same day or week in every part of the country, as while in many parts of the south of England and other favourable localities they might be carried out to the letter, it might probably be weeks before the same work could be done in the north of Scotland; but although our notes are given in season they must be applied according to circumstances. So far March has been the most unfavourable third month of the year we ever experienced, but Carrots, Peas, Beans, Onions, Leeks, &c., sown in February were put into the ground when it was in such good condition that we feel sure the young plants will appear strong and healthy as soon as the weather improves. It is surprising how much frost and cold weather such seeds as those named will pass through without being injured, only provided they have been sown when it was dry and covered with good soil.

**POTATOES.**—From the middle of March to the beginning of April is a very general time for planting the bulk of early Potatoes, and if the weather continues to prevent their being planted see that the young growths now forming on the tubers are not injured or drawn up weakly. Spread out the tubers in a single layer in the full light, but safe from frost, and the shoots will soon become dwarf, stout, and dark green in colour. It is a great advantage to have the tubers furnished with these at planting time, especially in a late spring. Potatoes in frames have been covered closely at night for some time past, as the least frost is fatal to them, and the darkness is not in their favour, especially as little air could be admitted when the wind was cold during the day, but do not pamper them a day longer than is necessary. Where tubers were planted in south borders or at the base of walls in February they will still be safe, but the sun during the day may induce them to grow a little, and where there is any chance of their being near the surface a spadeful of leaf soil or a forkful of manure should be placed over each set.

**CAULIFLOWER.**—Before the last severe frost set in we had planted out a number of autumn-sown plants from the handlights, and they have suffered rather severely, but others still in the frames have been covered at night and they are very robust. As soon as it thaws and the soil is in good order they will be planted out, but seed sown in the open some time ago will be a long time in producing large plants, and to succeed these in frames a quantity of seed should be sown under glass at once. We have just sown a box of each of the following varieties—Voitch's Extra Early, Sutton's King, Eclipse, Webb's Mammoth, and Veitch's Autumn Giant. We shall have at least 200 plants of each, and this will make a good batch for midseason supply.

**MINT.**—If there are any weeds on the surface of the Mint bed pick them off, and then spread manure over the surface to the depth of 2 inches. This treatment will produce Mint in abundance and of the finest quality.

**SAGE.**—Where plants of this were raised from seed last spring, and they are now growing close in the seed rows, lift every one of them and plant them in good soil, allowing 18 inches from row to row and 1 foot from plant to plant.

**SWEET BASIL.**—This is much valued in flavouring, but it is tender and must be raised under glass. Plants are easily raised from seed, and if a pinch of it is sown in a 6-inch pot many plants will soon appear, and as soon as they can be handled they should be transplanted into boxes, where they will soon grow large, and as each shoot is taken off a greater number will come.

**CELERY.**—Early plants which are now quite visible should not be kept in too much heat, as this has a tendency to ruin them. When about half an inch high transfer a number of them to boxes, giving them rich firm soil and keep them from 2 to 3 inches apart; place them in a gentle heat, and gradually harden off until they are planted out in May. Sow more seed, as those raised now are what will come in for the autumn supply. The seed as a rule germinates freely, and a little sown moderately thick in a 6-inch pot will furnish over 100 plants. Celery is very partial to water and should never be allowed to suffer from drought.

**TURNIPS.**—Make a good sowing of Sutton's Early Snowball as soon as the weather will allow. Plants raised after the middle of March are not so liable to run prematurely as those sown earlier, and those we recommend to be sown now will make a useful crop.

**PEAS.**—Autumn-sown Peas are about 3 inches above ground, but they have made little progress lately. They have not suffered much either, as before being staked securely they had a mound of earth thrown up on each side of the row, and this has been a great help to them. Those sown in December were visible a month ago, and they are no further forward now. Others sown in February have not appeared, but the seed is sound still and will remain so, and as mild weather would cause them to grow very fast, a good succession should be sown on the first opportunity. The sowings made now will be giving the supply in July, and as they do not remain long in good condition at that season, sow often and liberally.

**HOTBEDS.**—These are very useful, especially in gardens where there are no glass houses, and as Vegetable Marrows, ridge Cucumbers, &c., will soon have to be raised, collect material for the bed and form it as soon as possible. Leaves, stable manure, and anything that will ferment may be used in its construction. The whole should be mixed together and allowed to lie in a heap for a few days, then turn and let it rest again for a short time, when the bed may be made up. It should be a little larger than the frame which is intended to go on it, and it should be made very firm, as this is the only way of getting it to keep the heat for a very long time. Where hotbeds are plentiful they may be used for raising Lettuce, Cauliflower, Leeks, Onions, &c., just now, and the best way of treating them is to put a layer of good soil inside the frame on the surface of the bed and sow the seed on the top of this.

**BEANS.**—Make a good sowing of Carter's Leviathan, which is an excellent Broad Bean. Syringe those freely which are coming on under glass. Cooling's Ne Plus Ultra, which we sowed ten weeks ago, is now bearing heavily. Sow a large batch of more seed of this variety or Carter's Long Sword, as vegetables are sure to be scarce in April and May. As soon as the young plants get into the rough leaf they will bear hard forcing, and may be pushed on freely.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Early House.*—The young shoots having been neatly tied in close to the base, and the superfluous growths removed or pinched back to form spurs, the trees should be allowed to make free growth until they are sufficiently advanced for the general tying down to the trellis. Any shoots that show a tendency to become too strong should have the points pinched out before they have time to disturb the balance of the trees. Proceed with thinning the fruits, which must be regulated by the strength of the trees, always bearing in mind that a liberal per-centage must be left for removal after the stoning period. Size and quality being the first consideration, one Peach to every square foot of trellis covered with foliage will be found a heavy crop, and any excess will affect the weight of each fruit, and shorten the lives of the trees by impairing their vigour. When the weather is bright the trees will require syringing with tepid soft water twice a day, but in dull weather the syringing must be omitted or done sufficiently early to allow the trees to become fairly dry before night, but when syringing is not practised a genial condition of the atmosphere should be secured by damping in the morning and again before night, the first with tepid water and the second with liquid manure. Mulch the surface of the borders with short manure, and supply tepid water, afterwards tepid liquid manure. On fine mornings turn off fire heat early, and increase the ventilation with the advancing temperature. Keep a steady night temperature of 60°, with a rise of 10° to 15° by day until after the fruit is stoned, when the ripening may be hastened, if necessary, by a higher temperature.

*Succession Houses.*—Disbud the trees when sufficiently advanced, and pinch for spurs, and cut away all shoots that are not likely to be wanted for the support of the present or the production of the next year's crop of fruit. In disbudding, commence at the extremities of the trees, and work gradually down to the base. Remove small or badly placed fruits as soon as the most promising for the crop can be decided upon. A temperature of 55° to 60° at night, according to the advanced condition of individual houses, will be sufficient, with 10° to 15° rise by day. Syringe twice a day, and water as advised for the early house.

**Late Houses.**—The houses to ripen fruit in August will now be in flower, and will need a day temperature of 50° by artificial means, and 10° to 15° advance from sun heat, with a free circulation of air, the night temperature falling to 45°, with a little night ventilation to prevent the deposition of moisture on the blossoms. Late houses should have a free circulation of air with a view to retarding the flowering, but after the blossoms expand they should be kept safe from frost, and the heat turned on in the morning so as to raise the temperature to 50° and admit of ventilation. See that the inside borders are in a thoroughly moist condition.

**CUCUMBERS.**—Stopping, thinning, and tying the shoots will now require frequent attention. More especially is this the case with the plants that have been fruiting all the winter, which with favourable weather will now be making growth freely. Remove all decayed portions of wood and leaf, encouraging a free growth of young wood, which, as a matter of course, should be tied to the trellis, removing the old wood where practicable to make room for the young. Take off an inch or two depth of soil from the surface of the bed, not unnecessarily disturbing the roots in so doing, and give a dressing of two parts light turfy loam and one of well decomposed short dung, free from worms, and a sprinkling of charcoal. Fresh roots will push freely into the new compost, after which, when circumstances require it, water them copiously with tepid liquid manure in a diluted state. These matters being attended to, the plants will continue in a fruitful state some months longer, being nearly, if not quite equal, in prolificness to plants raised from seed in the early part of January. Maintain a night temperature of 65° to 70°, and 70° to 75° by day from fire heat, allowing an advance of 10° to 15° with sun, and maintain the bottom heat steady at 80°, never less than 70° nor higher than 90°. Add some more soil to the hillocks of young plants as the roots protrude through the soil.

**MELONS.**—Rapid progress has been made during the bright weather of the last few days, hence the stopping, tying, and thinning of the shoots must be attended to almost daily now that the growth is active. Remove all blossoms from the plants swelling their fruits in the early house or pit, and place the supports to them in due time to relieve the plants of the weight. Pieces of deal half an inch thick and 6 or 7 inches square, suspended in a sloping direction by four pieces of wire from the trellis answer well, as do square pieces of small-meshed garden netting fastened to the trellis by four pieces of string. Examine the soil and see that the plants do not suffer from insufficient supplies of water. They will now, especially if the roots are growing in a rather confined space, be in a condition to take a weak application of liquid manure, keeping it away from the stem, which brings on canker, upon the appearance of which quicklime should be rubbed into the affected parts. Ventilate a little on bright mornings when the thermometer registers 75°, increasing it as the temperature advances, keeping the house through the day at 80° to 85°, and closing sufficiently early to allow of a rise to 90°, with plenty of atmospheric moisture, syringing the plants and house twice a day during bright sunshine, closing about 3 P.M. Make additional plantings, pressing the soil around each plant, and should the sun be powerful at the time shade the plants for a couple of hours for a few days, when it must be discontinued. Keep young plants near the glass to prevent their becoming drawn, and make successional sowings as circumstances require, keeping a sharp look out for slugs, searching for them after dark with a lantern, as if allowed to have their own way they in a short time do irreparable mischief.

#### PLANT HOUSES.

**Cattleyas.**—If *C. Trianae*, *C. Mossiae*, *C. intermedia*, *C. gigas*, *C. Mendelii*, and *C. Percivaliana* have been wintered in a night temperature of 60° they will now be starting, and should be top-dressed or repotted, as the case may be. Those that require repotting are best done before new roots have extended to any length, for they are almost certain to be injured in the operation. We prefer repotting these plants just as the roots show signs of starting from the base of the pseudo-bulbs, and therefore they should be pushed on from time to time as they are ready. Those repotted last year will only need the surface peat and as much of the sphagnum moss as possible removed without breaking or otherwise injuring the roots. Supply fibry peat and living sphagnum. All the top-dressing should be completed before those that require potting are commenced. Cattleyas are amongst the most difficult of Orchids to repot without injury to their roots more or less, for the roots cling tenaciously to the sides of the pot. Pans are the best for these plants, and plenty of various sizes should be in the house in readiness, also plenty of clean crocks in various sizes, charcoal in lumps, peat fibre, and sphagnum. These are worked in separately as the work of potting proceeds. It is impossible to turn these plants out of the pans in which they are growing without destroying a large quantity of their roots; therefore, the pans should be broken. The base of the old pan should be removed and as much of the remainder of the pan as possible, all the portions clinging to the roots being left. The old compost, if very much decomposed, must be removed; but, if in good condition, only those portions that can be taken without disturbing the roots. When all the old compost is removed potting must be carefully performed or the plants will decline in health. A pot, according to the size of the pan, should be inverted in the centre, and then the plant placed into position and crocks and charcoal carefully laid amongst the roots until the pan has been more than half filled. Place a little moss over them, and fill the remaining space amongst the roots with peat and moss, using about one-third of the latter. As the work proceeds lay large pieces of charcoal amongst the peat and moss, so that the new roots, when they are made, will have something near the surface to cling to. The moss used must be so placed—not too far below the surface

—that it can be picked out annually, for it decomposes much more quickly than peat fibre. When these plants are potted a good shift should be given them, so that they will stand for three years, or as long as the fibre will remain in good condition. It is important that the peat fibre be good, for these plants do not long remain healthy with decayed compost about their roots. They must be watered with great care for some time yet, especially those newly potted, giving no more water than will keep the material about their roots moist and the pseudo-bulbs from shrivelling. Syringing amongst the pots may be freely practised, and a little more moisture may now be maintained in the atmosphere of the house. Plants growing on rafts may be mossed and top-dressed, and the same applies to those growing in baskets; if larger are required they may be placed in them without attempting to disturb the old basket.

**Oncidium.**—All that are growing with the Cattleyas may be top-dressed, except those that it is necessary to place into larger pots, pans, or baskets. These plants are less difficult to pot than Cattleyas, for their roots are not so easily destroyed. Many *Oncidium*s will flourish in the same basket for years provided they are top-dressed with moss and peat annually. When these plants are placed in baskets plenty of charcoal should be given them, and their roots will soon become attached to it; the compost used for them should be near the surface, so that it can be removed when decomposed. It is sometimes difficult to pick out the whole, but it can generally be washed out, and when this is done the baskets must be allowed to drain thoroughly before the new compost is applied. Those in pots or pans that need a larger size should have them most liberally drained, for these plants root most freely upon the surface. The majority do well in peat fibre and a little charcoal intermixed, with a good layer of moss on the surface. When repotting any plants decomposed soil should be removed and the roots washed clean in tepid water. If the material used for potting is good, and too large shifts are not given, they will be in sweet condition in the space of two years, when they should require larger pots or pans. More water may now be given to the roots of those starting, while those repotted must be watered very carefully until they are growing and rooting freely. If these or any Orchids are overwatered after they have been repotted they are certain to sniffer, but with care they will start freely and vigorously into growth. For the present make no attempt to grow the sphagnum on the surface of these plants; they can be surfaced after they have commenced growing freely, and then the moss can be encouraged.

**Thunias.**—These have been resting in some moderately cool place, and may now be introduced into a temperature of 60°. If given a good soaking of water and syringed daily they will soon commence growing, when they should be shaken out of their pots and repotted in fresh ones. These Orchids are not very particular about soil, and will flourish in almost any compost. They do wonderfully well in fibry loam, one-seventh of cow manure passed through a fine sieve, sand and a little charcoal, or they may be grown in equal portions of peat and loam. Water carefully until they are growing and rooting freely, then liberal supplies may be given.

## THE BEE-KEEPER.

### EXTRACTING HONEY.

ADVANCED bee-keepers are always ready to expatiate upon the merits of the extracting system, and to denounce the old-fashioned cottage skep, not only because of its inhumanity, nor yet because the weight of honey derived from stocks so managed is less, but because they say honey taken from combs which have at one time contained, or at the time of taking honey do contain, some pollen, brood, or other contaminating substance which is extraneous to pure honey, takes away its rich flavour and the sweetness appertaining to honey taken from white comb in which pollen has never been stored nor brood raised. It is, of course, admitted that honey taken from such combs is inferior to that taken from virgin comb. The old system is, then, essentially at fault. Every new one must directly aim at getting pure honey and untainted; but do these advocates of extracting extract from pure comb? Do they not rather choose old tough combs in order that they may the better withstand the action of the apparatus which is to throw out the honey? Are not these combs used for extracting from often partially filled with brood in all stages of existence and with bee bread? Is it possible, can anyone imagine, to extract the honey only without throwing forth some brood and pollen? Where, then, is the superiority of this honey over that taken on the old plan with less trouble, less expense, and a minimum of risk?

In order, however, that the extractor may be of the

greatest possible use to the bee-keeper the honey must not be left in the comb until sealed or the loss of time would be great, so these apiarians who advocate the taking of pure honey only extract it in a partially unripe state, when it is of very poor quality and quite unfit for sale. Whether this is recognised here or not it is certainly well known in America, and the evils of this method of increasing the honey flow are acknowledged by great authorities, as may be seen from the President's address delivered to the North American Bee-keepers' Society, which met on the 8th of December last. The following passage will give some idea of the drift of the essay:—"When is honey ripe? With the system of extracting when the honey is unsealed there is no uncapping, and bees have plenty of store room, but the quality is inferior; and right here a friend would step in with his ripening can. But we have made no light mistake, for in the past our honey has been handled too much as if it could lose nothing by having it come in contact with the air. What imparts that peculiar aroma to honey and gives each kind of honey a distinct flavour? Is it not largely a volatile oil? . . . and in evaporating and otherwise coming in contact with the air we lose this."

Possibly the States apiarians can form quite as good an idea of the extractor as any English apiarian; certainly more honey passes through their hands each season. If run honey thrown from the combs before ripening is so inferior in quality, losing flavour and its rich aroma, the producer is damaging the market; if, again, the honey is allowed to remain in the cells until they are all completely sealed the extractor may be used with advantage to save the combs, but all the other advantages appertaining to its use are gone. I had always been under the impression that the less honey was exposed to the action of the air the better the quality, and yet if the extractor and ripener are brought into use a process of evaporation must take place which is essentially damaging to the honey, and in addition giving increased trouble to the bee-keeper. To quote again from the same source:—"Many find that to extract honey when one-third capped answers well, the honey to be put into deep tanks holding about 600 lbs. each, and left for a week. This causes the light thin honey to rise to the top; generally it is not 10 per cent." Now, possibly the great bee farmers of America may profit by this spurious ripening of honey, but it is very questionable, and, in fact, the idea seems already to be taking root that such a clumsy method is practically worthless.

The objection to leaving the combs until completely capped is the loss of time entailed, and this in the honey flow is great, but better far to get a less quantity of extra quality than a superabundance of sugary syrup lacking the flavour and good keeping properties of honey, resembling it only in that if it had had time to do so it would have become the real genuine product. Would it not be better to sacrifice the extra quantity? Is it feasible to spend time in extracting every few days, and money in buying extractors, when the result is inferior produce if the thin honey is not separated from the thick and ripe, and if such a separation is made then loss of flavour and loss of weight, with the result that the finest quality only brings the same price as the honey taken from the combs on the old-fashioned plan—that the poorer quality is, when the market is glutted, unsaleable, and at any time only realises a very low price, and from this price deduction must be made to pay for the apparatus and the time and trouble expended upon its use? For those who use the extractor to blame the cottager for the inferior quality of his honey is presumption; to them, perhaps, the old adage will occur. Better far take honey from old combs containing brood and pollen rather than take it unripe and thin and watery from combs free from contamination. Honey of very fine quality can indeed be taken from old combs if only care is exercised not to indiscriminately break up the combs and all their contents together. If all the better parts of the comb are run into one pan, and the inferior and pollen-contaminated portion into another, the result is that the former

will be of a really fine quality, far superior to the sugar-and-water liquid sold to those who are yet unable to detect when honey has been treated in a manner tending to deprive it of its exquisite flavour, and to reduce it to a flavourless compound which is totally different to the honest production of the bee gathered in the natural way, stored in due time, sealed when ripe, and extracted in a proper manner, taking due care to exclude all extraneous matter, and to expose it to the action of the air for as short a time as possible. By all means let us increase the yield of our stocks if we can, but not at the expense of quality. If we cannot get good quality honey in greater quantity we must be content to wait, and may feel sure that if we desire to damage bee-keepers nothing more surely will effect the purpose than teaching them to palm off upon the public in the name of honey a spurious liquid which in due time would have become honey, but which the impetuous haste of the bee-keeper has turned into a tasteless syrup.—FELIX.

#### TRADE CATALOGUES RECEIVED.

Webb & Son, Wordsley, Stourbridge.—*Catalogue of Special Manures.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Vines not Starting Freely (W. W.).**—This might be due to over-cropping last year and imperfectly ripened wood, or perhaps the atmosphere of the house has not been kept sufficiently moist. Damp the paths, stages, or border, and on fine bright mornings syringe the rods with soft tepid water. A little weak liquid manure may be sprinkled about on the floors and paths, the ammonia arising from which will assist the starting.

**Insects in Soil Injuring Ferns (G. C.).**—The best plan will be to repot the Ferns, carefully removing as much of the old peat as possible, and employ fresh, shading the plants for a week or two until they recover from the potting. Remove the old soil, and exercise as much care as possible to prevent any being mixed with the fresh material. Take some distance away or burn it, and on no account employ it again for the plants.

**Bones and Bonemeal (F. G.).**—The sample of "turnings from bone buttons" would be excellent for mixing with soil for potting most kinds of plants. Being so finely divided its virtues will be the more readily available, and at the same time will be yielded for a considerable period. The crushed bones would be of service for mixing with the soil for Vines, also fruit trees and Roses in pots or borders, also for plants generally that have to remain in pots for a considerable time. It would improve the mechanical condition of soil, and act as a steady fertiliser over a long period. Its dark colour is quite immaterial for the purpose in question. A mixture of the two kinds would be good for Chrysanthemums.

**Kennedya and Lasiandra (Borderer.).**—We do not know a *Kennedya* bearing the name exactly as you give it, but it is probably a misrendering of *K. inophylla floribunda*, which you will find in the catalogues of the leading nurserymen. *Lasiandra macrantha* is much more straggling and loose in growth than the variety *floribunda*, which should be grown for pots where bushy plants are required. The other is more fitted for training against a wall or pillar, but by shortening the stems and pinching the growths early in the season the plants can be rendered more compact. If, however, you wish to cultivate plants in pots procure the variety named, and you will experience little difficulty with it.

**Raising Seedlings (Hackneyarian.).**—A box 2 feet deep will be suitable for raising Stocks and similar plants in. As manure cannot be had, 1 foot in depth of any kind of rubbish may be put in, spreading on this about 8 inches of free soil, fertile garden soil, with leaf mould and sand, answering well, the upper 2 inches to be sifted. The seed may be sown in April the seed kept moist, and the box covered with glass. The Sweet Peas and Mignonette seed will germinate in due time if the soil is kept moist.

Current trees may still be planted if the roots are kept moist when out of the ground, but autumn is the best time. The price of trees depends on their size. Cocoa-nut fibre refuse can be had in small quantities from nurserymen and florists, in large quantities from advertisers of the material.

**The Date Plum (W. J., Croydon).**—*Diospyros Lotos* is the European Lote or Date Plum, and grows wild in countries bordering the Mediterranean. It produces fruit of the size of a Cherry, of a yellow colour and a sweet astringent taste, and it has been recommended as a cure for diarrhoea. *D. decandra*, a native of Cochin China, bears a large berry, of a yellow colour when ripe, with an austere and somewhat sweet taste and disagreeable smell; but it is eaten and sold in the markets in the northern provinces of Cochin China. The wood, when of sufficient age, is of a fine, compact, regular grain, heavy, very white, veined with black, and sometimes black at the heart, and is highly esteemed for cabinet-work. The fruit of *D. psidioides*, a native of Peru, is an inch in diameter, with an ungrateful smell and an insipid taste. *D. Kaki*, a native of Japan, produces a fruit like a yellow Plum, which the Japanese eat to such an extent as sometimes to cause an attack of diarrhoea. It is sometimes imported to this country from China as a dried sweetmeat. It is preserved in the same manner as the Fig.

**Vines and Peaches (F. J.).**—We do not syringe our Vines after the leaves commence unfolding, except giving them a thorough washing, not a mere sprinkling through the syringe once a month or so to keep the leaves quite clean. A genial atmosphere is maintained by syringing every part of the house except the Vines early in the afternoons of bright days when the house is closed, damping the paths in the morning according to the weather. Some growers find it advantageous to syringe Vines regularly in districts where red spider is prevalent. Syringing or non-syringing is very much a question of management in other respects, and no inflexible rule can be stated on the subject. It is a question on which individuals must exercise their judgment. The laterals should be thinned gradually, so that the best are eventually retained, about 18 inches apart so as to afford space for full development of the leaves; but these permanent laterals must be safely secured before all the others are removed, or an accidental breakage of one of the former would leave a blank not easy to be filled. As the Peach trees are growing you must keep them in the house for some time, or until the weather is so mild that they can be placed outside without receiving injury. If you put them out now you will kill them. They must be prepared and hardened as if they were bedding plants, then planted out as you propose. Cut out the branches that have produced no growths. We are unable to obtain the address you require.

**Cypripedium spectabile (T., Surrey).**—You have not been misinformed as to the easy culture of this hardy Orchid, nor has its beauty been overestimated, as it possesses merits which should make it a general favourite; and when its perfect hardiness is taken into consideration with its present inexpensiveness there is no reason why everyone should not possess one of the very best perennial Orchids. The plant is easily distinguished from all others. It grows from 1 to 2 feet high, the stems being more or less covered with leaves of a light green colour, and conspicuously veined. The flowers, which are borne singly, or from two to four on the stems, are very showy; the sepals and petals are spreading, ovate in form, the petals being much the widest, pure white in colour; the lip is very much inflated, of a rich rose colour, sometimes nearly crimson. The soil best suited for it is good peat and coarse sand, with some sphagnum chopped up fine and mixed with the peat. If grown in pots several should be placed in a large pot and kept plunged in moss or fibre in a shady place. When well grown it is a most beautiful plant for exhibition purposes, and it can be readily forced. It can be equally well grown if planted outside in peat and sand in a shady place or on the rockery, where it is quite at home with many of the Primulas, Dodecatheons, and Ferns. It forms a lovely companion for Ferns. The stems springing up from among the light green fronds of the Lady Fern are exceedingly attractive, and the plant thoroughly enjoys such a home. We have had it planted in old stumps, when it seemed to be peculiarly happy.

**Constructing Peach House (J. L.).**—You do not state whether the house is to be erected against a wall already up, or whether a wall will have to be built, as we presume you intend to have a lean-to. This we should not have if a wall has to be built for its support. Granted you require the house against an existing wall, and that it has a southern aspect, we should have a house 12 feet wide, having 3 feet height of front lights, and these not more than a foot clear of the ground level, the front wall being built pier fashion, with 2 feet openings, arched over to allow the roots from the inside border to pass into the outside one. The depth of border will need to be 3 feet, so that you must have the front wall accordingly high with proper footings. The height of the back wall will need to be 11 feet 6 inches, and this will give you a proper slope for the roof, the front lights being 3 feet, and with the brickwork 4 feet above ground. The height of the back wall must be calculated from the ground level. To accommodate two trees in front the house must not be less than 24 feet long, better 30 feet, the front trees being trained to a trellis, fixed about 16 inches from the glass, and the front part curved so as to take off the angle formed by the eaves. The front trellis must only be taken up about two-thirds the house, calculating from the bottom of the rafter, so that the upper part of the house will remain clear and admit light to the trees at the back. It would be an advantage were the house a three-quarter span so as to keep down the back wall to a height of about 9 feet 6 inches, the front trellis in that case being taken up to the ridge. You will need lights not less than 2 feet wide at the top of the house its entire length, and the whole of the front lights should be made to open by crank and lever movement. If there is no wall we should advise a span-roof house with the ends north and south, and 18 feet wide so as to take trees on both sides of the house, having it 30 feet long. It will be more costly, but not much more so than a lean-to.

**Lihonia florihunda Culture (R. S. T.).**—A successful cultivator of this plant treats it as follows:—“Small bushy plants laden with their pretty orange scarlet tubular flowers are valuable for dinner-table and room decoration, producing a very charming effect. It is also suitable for arranging amongst other plants in the conservatory. Unless large specimens are

required small plants are the most useful for general decorative purposes. After flowering they should be pruned and placed in heat. The young shoots when an inch long make good cuttings, and should be inserted in light sandy loam, the pots being placed in a moist gentle bottom heat. When the cuttings have rooted they should be transferred singly into 2½-inch pots, employing a compost of two parts turfy loam, one part leaf soil, and one part well-decomposed manure, with plenty of sand to render the soil porous. After potting the plants must be kept in a close house and shaded for a few days; afterwards assign them positions near the glass, with full exposure to the sun, in a temperature ranging from 65° to 75°. Syringe them twice on fine days, and frequently pinch the points out of the shoots to induce the plants to become dwarf and bushy. As they increase in size they must be potted, employing pots an inch larger each time. About the end of June they may be gradually hardened off and placed in cool pits or frames, which must be ventilated freely on bright days, and supply the plants with plenty of water; liquid manure may also be given two or three times a week with beneficial results. About October the plants must be taken in the greenhouse, where they thrive in a temperature from 45° to 55°. By the end of November they will commence flowering, and will remain in great beauty till March.”

**Grafting Wax (G. H.).**—There are various preparations used in grafting fruit trees. Some of the mastics require to be used warm, but the following may be prepared and used without being heated:—Yellow wax, 1 lb.; turpentine, 1 lb.; Burgundy pitch, 8 ozs.; mutton suet, 4 ozs. Melt all together and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers. Liquid grafting wax is a very useful application, and is, perhaps, the most convenient for the purpose of all the mastics used for covering wounds and grafting. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly the alcohol is prevented from evaporating. Rosin, 1 lb.; beef tallow, 1 oz.; spirits of turpentine, one tablespoonful; alcohol (95 per cent.), 6 ozs. Melt the rosin over a slow fire; when melted take it off and add the beef tallow, stirring it constantly; let it cool down somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If in course of time it becomes too thick, the addition of some alcohol will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling or hot water to accomplish this. They are generally used in preference to clay in nurseries where grafting is extensively carried on, because more expeditious; but where only a few trees are grafted well-prepared clay answers every purpose.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (H. T. F.).—Your plant is *Dendrobium crassinode*, and a rather pretty variety.

#### COVENT GARDEN MARKET.—MARCH 17TH.

No alteration from last week. Cucumber trade very dull indeed.

## SEED TIME.

BARLEY, Oats, Clover, Rye Grass, the mixed seeds of alternate husbandry; Spring Tares, White Mustard, Cattle Cabbage, and Thousand-headed Kale, Sainfoin, Lucerne, Mangolds, Swedes, Parsnips, Carrots, and White Turnips are among the principal crops to be sown in the course of the next few weeks. We have given particular attention to procure good seed of whatever sorts had to be purchased, for we make it our especial object to procure seed both clean and fine. For example, we required a rather large quantity of Black Tartarian Oats, but we had to reject more than one sample foul with the seeds of weeds and other corn; we also declined buying some Fen Oats pressed upon our notice as really excellent seed, but to our mind the large quantity of small tail corn in the sample gave promise of anything but an excellent crop. Upon pointing this blemish out to the vendor he was loud in his assurances as to the vitality of the seed, and we had some difficulty in making him understand that it was not the vitality of the seed, but the vigour of its growth after germination that we considered questionable. Eventually we purchased a fine clean sample of short, stout, even-sized grain at the high price of 26s. per quarter, and judging from experience the extra outlay of 6s. per quarter should prove a profitable investment. To obtain the best possible crops the sowing in good time of first-class seed is the crown and finish of our work at seed time, and we cannot too strongly deprecate the erroneous practice of sowing inferior seed.

A dry February and so much hard frost must confer the advantage of a good seed bed for spring corn generally. Early sowing is doubtless desirable, but it is well to wait till the soil is really dry enough for the free action of drills and harrows. Barley sowing should then come first, and we only wish our readers had Excelsior drills to apply artificial manure to the soil at the same time.

Oat sowing follows Barley closely, and no corn answers better for a dressing of manure, which ought also to be given to Clover and mixed seeds. Foul land will probably be in condition to be cleaned early, and if poverty-stricken as well we cannot do better than sow it with White Mustard—20 lbs. of seed per acre, giving a dressing of 1 cwt. of nitrate of soda per acre as soon as it is well above the surface; and when the Mustard has shed its blossom and the seed pods are fully grown but still green, at once plough in the Mustard, and sow another crop of it if the season proves favourable. We thus get clean soil admirably stored with fertility in the most economical manner.

Of green crops for the flock Spring Tares follow Swedes, Cabbage, and Rye, and well will it be if we can spare enough land for successional sowings till June. A large piece of Rye Grass or Rye Grass and Clovers sown with a corn crop is a wise provision for next spring, and we may well pass in review all such useful crops as Sainfoin, Lucerne, and Cabbage, the last named crop being alike valuable for cows and sheep. Let it not be forgotten, too, how exceedingly valuable Green Maize is for cows and store cattle in summer. This crop is not sown till the end of May, as the young growth will not bear exposure to late frosts, but it grows with such singular rapidity and vigour as to exceed by many tons per acre the bulk of any other forage crop.

Upon the home farm Turnips and Mangold should not be grown altogether to the exclusion of Carrots, for although a somewhat expensive crop there can be no doubt of its value for dairy cows as well as for horses. Sliced Carrots and bran with meadow hay is the diet of our cows for the last three months of the year, and we have never found this sweet wholesome root affect the flavour of the milk hurtfully.

## WORK ON THE HOME FARM.

Weather of such extraordinary severity in March has rendered extra care necessary among the lambs. We were asked for lamb cloths to put on the hurdles enclosing a fold for some of the ewes and forward lambs on Turnips in an exposed field, but we were able to afford much better shelter by having hurdles thatched with straw put up round the fold, and at the same time to avoid an outlay of £4 or £5. We now fully realise the beneficial effect of a liberal dietary for the flock, only one weakly lamb having succumbed to the trying influence of snow and frost. We hear with regret of losses of both sheep and lambs from insufficient food and exposure to cold, and we repeat that sheep do suffer from exposure to cold and wet, notwithstanding their thick wool covering. When will farmers see that it is to their interest to provide ample means of shelter and plenty of good food for all the animals of the farm? Do not attempt undertakings beyond the scope of your means. Fifty sheep well fed and well sheltered will always prove more profitable than a hundred turned out on bare pasture to "take their chance."

Corn-drilling and other work on the land has been retarded by frost and we have turned to Wheat-threshing at last, although the advance in price is so slight as to make very little difference to the final result. It was clear, however, that when the full pressure of spring work set in corn-threshing would prove such a hindrance that it was better to get it done beforehand. The carting of faggots, timber, stones, and gravel, has also been pushed on as fast as possible, as such work should soon be finished now. Hedgerow timber grubbed during winter has been taken off the fields, and all grass land must now be cleared of wood of all kinds, fallen branches and twigs picked up under trees, and stone-picking also done, preparatory to bush and chain-harrowing and rolling. Growth on poor pastures will be very late this season, poverty of condition always proving a hindrance to free growth, but fertile pastures well dressed with manure spring into free strong growth with the first change to mild weather.

Fences and gates have all been examined and all repairs done. We have many fences requiring a coating of tar, but this work is reserved till summer. We hope, then, to do all that we can to have all bare or weather-worn wood and ironwork of fences, gates, and farm buildings, carefully dressed with hot tar, both for appearance and protection of the property entrusted to our care. It is undoubtedly a weak point upon farms generally, this negligence of such work which meets the eye on every hand, and yet nothing can possibly justify it, for the outlay cannot be material when tar can be had for 4d. a gallon.

MESSRS. F. & A. DICKSON & SONS' "BOOK OF THE FARM."—This neat annual, besides containing an article on laying down land to pasture, publishes an abstract of Professor Carruthers' report relative to "Cheap Seeds." The Professor expresses his belief "that the great progress made in supplying good and pure seeds extends to the larger houses throughout the country, but from some experience fears 'that the smaller dealers in market towns distribute worthless materials among farmers.'" He gives examples in support of his view, and remarks that in one case Meadow Fescue bought by a member of the Society in Kent, from a merchant in a neighbouring town, contained 76 per cent. Rye Grass, 4 per cent. Holcus, and 4 per cent. of other foreign species. He says, "So long as farmers seek a low-priced article and accept and sow worthless seeds without complaint, they will be supplied."

## FROZEN MEAT.

As affecting the interests of British farmers in one way and the great body of consumers of farm produce in another, the importance of the trade in frozen meat cannot be overlooked. Not in the cropping of the

lands alone, but in other matters, there is perhaps a tendency to "go into extremes." As soon as any particular method of routine finds favour there is something like a rush towards its adoption, the result of which is markets become overstocked and "depression of trade" is the natural concomitant. So long as the production of grain was profitable so did the acreage increase, not in this country, which is a mere speck on the food-producing surface of the world, but in other lands where vast areas awaited cultivation; hence the extraordinary supply of Wheat and the correspondingly low value of the produce. This low value, which in many cases was certainly not remunerative, suggested the advisability of laying down land to grass with the twofold object of saving labour and growing meat. In certain districts this change in the method of procedure was doubtlessly sound and, carried out with judgment, profitable. But prudence is not always the accompaniment of change. It is one thing to lay down land to pasture in a stock-rearing and dairy farming district; another thing to relinquish the cultivation of grain and root crops all over the country. Is there not just a danger of the change suggested being carried out too far and too generally?

It does not follow that because Wheat-growing has not been profitable during the past two or three years that it will for ever remain unremunerative; neither does it follow that fortunes will be made by the rearing and fattening of stock in this country. It is perhaps questionable if all, or even half, of the farmers of Great Britain are aware that the acreage of Wheat in the United States of America has decreased in one year to the extent of 5,000,000 acres; and they have possibly no adequate idea of the increasing magnitude in the importation of meat preserved by the agency of frost from the Antipodes. It is proved beyond all question that meat can be brought from New Zealand and other colonies on the other side of the globe and distributed to consumers in this country as fresh and as sweet as from our native pastures. This statement will not be accepted by the majority of people, and it is just because of this innate incredulity of the British race and the prejudice that exists in favour of home products that danger lurks of one being left behind in the competition of the world.

Having recently inspected the refrigerating stores of Messrs. Nelson Brothers, shippers, a brief reference to their extent and the process of storing thousands of frozen sheep and huge piles of beef may not be devoid of interest to both producers and consumers of meat. The stores extend from the Thames, and are approached through a huge tunnel, like a railway tunnel, but more lofty, with a line of rails laid up the centre to a length of some 500 feet. On each side of this main thoroughfare the stores are arranged in the form of large and lofty cavern-like arched chambers, each with an embrasure, barred and shuttered. On removing the shutters and touching a button the interior is revealed, illuminated by the electric light. It is a strange weird wintry scene. The thermometer registers 22°, or 10° of frost. Snow crystals hang from everything to which they can adhere, and the floor is white and glistening. From the base to the ceiling the sheep are packed like a wall, each sewed up in a white sheet, sides of beef and thousands of legs of mutton being disposed in a similar manner. There is a steady outflow of 2000 sheep weekly that were grazing three or four months previously on the pastures of New Zealand. Thirteen thousand sheep had just been landed by a large wharfinger, who has had harges specially fitted for transferring meat from the ships to the stores. The trade is great now, and far-sighted mercantile persons do not make provision of the nature indicated without having some good reason for its extension. It is, in fact, calculated that the cattle-rearing resources of New Zealand are equal to a supply of 100 tons a day for an indefinite period. Already the trade is having a marked influence in districts where markets are established in thickly populated districts for the sale of "frozen meat," in a general and not unappreciable fall in prices of home-raised meat. Taking one market, for instance, Croydon, thousands of breasts, necks, shoulders, and legs of mutton have been sold for weeks past, the first at 3d., the second at 4d., the third at 5d., and the last at 6d. per lb.; and what is more, not a few—no one knows how many, but the fact is undoubted—legs of frozen mutton have been thawed and sold as English mutton at 10d. and 11d. per lb. London butchers, of course, must "live," and it is very certain they *will* live well if they can find or make an opportunity of doing so; but it is not suggested that they are all alike, numbers of them being far too high-minded to deceive the public with their wares. But the fact that "frozen meat" is sold as English is not bad testimony as to the quality.

Nor are the operative classes the only purchasers of antipodean meat. Some of these are perhaps the most prejudiced against it, or have been. The well-to-do, not to say the wealthy, buy large quantities, and what may be termed educated palates are satisfied; but servants did not "take to it" readily. The difficulty has been got over, however, in some cases by having the meat cut up English fashion and sent in thawed; or, to put it from the servants' point of view, "the master has given up buying that nasty foreign stuff, and now we have beautiful English meat."

With some little hesitation I purchased a leg of mutton from the Cannon Street Stores, just as taken from the pile, for there is no picking and choosing, thawed it according to instructions, and cooked it a week after taking it home. The head of my domestic arrangements did not compliment me on my investment, and the coming dinner was not regarded as a treat in store, but rather the reverse. A disposition was manifest to find fault with the dinner, but it was of no avail; prejudice vanished, and I am now strongly pressed to buy a frozen leg every week and to get some beef besides. No better mutton was served by the same cook. The weight was 10 lbs., the price 5s.; a week previous an English leg of exactly the same weight cost 9s. 2d., and this was certainly no better, if as good as the former—hence the request for more.

But how is the temperature of the refrigerating stores kept down? Frost is the preserver of the meat—Nature's preserver—the frost being produced "by steam." The air is compressed into cylinders by powerful engines, the cylinders being surrounded by water. The heat generated by compression is extracted by the water, and the air then transferred in culverts and pipes cold and attenuated to where it is required, the atmosphere of the stores being precisely similar to that on the tops of mountains when the thermometer registers 22°, while the air is mild and muggy in the valley below. As a triumph of science and commercial enterprise the frozen meat industry is very remarkable, and home producers and consumers will be no worse for knowing a little about it. The branch of the business referred to is at 15, Dowgate Hill, Cannon Street, London.—J. W.

## FARMERS AND GARDENERS.

I THINK it is my duty to explain myself with reference to "Thinker's" remarks on my contribution on the above subject on page 138. With reference to the English and American producer, I will admit that they are about equal as far as their total freightage charges to the London market are concerned, but I am sure the Americans have great advantages over us in many respects, for they have fewer rates, no extortionate tithes to pay, unrestricted cropping, and they can often buy land as good for the amount of money that the farmer here has to pay as rent. I may state that cultivation in America is considerably cheaper, for they have a rich virgin soil, which for the present requires no manure, and also is free from weeds. They are not also subjected to climatic changes as we are in Britain, but, having settled periods of weather, they can cultivate their land uninterruptedly and harvest their crops without fear of their being spoiled by unfavourable weather. Another grievance of the British farmer is the deplorable condition of many of our rivers. In many of the river valleys the land is only just above the level of the water, thus not allowing the land to be drained properly, as there is not sufficient fall to the river. This is an evil which could be remedied, first by deepening the rivers where required, and secondly by removing surplus weirs in the river which unduly keep the water back simply for the purpose of keeping sufficient water to work a few mills. I think inferior culture of the soil is due—(1) to the insecurity of capital in land; (2) the absence of sufficient capital for practical working purposes; (3) land being unfavourably situated with reference to floods; (4) the refusal of landlords to keep farm buildings in repair; (5) too much restricted cropping; (6) the ignorance, laziness, and want of experience of certain farmers. The above I consider some of the principal causes of bad farming.

I agree with "Thinker" that the importation of so much poultry and eggs is a puzzle. But could not someone enlighten the farmers why the foreigner can supply the British public with the enormous amount of poultry, and eggs? Is it that they have a more genial climate? Are taxes, rents, &c., less there than in this country? Is poultry, reared on a small or large scale? And also are there any great secrets in the rearing and management of their poultry? I think that any information on the above subject would be most thankfully received by those interested in the question. As poultry rearing has been so often referred to as one of the things which will make farming pay, I think the farmer may claim some right to get practical information from those who are continually reminding him of poultry rearing.—A. E. H.

**WEBB'S SAMPLE CASE OF PURE GRASS AND CLOVER SEEDS.**—We have received a small case of these seeds from Messrs. Webb & Sons, Stourbridge, very neatly packed in stiff paper packets bearing the botanical and common names of the plants. In an accompanying list is given the respective number of seeds per cent. of each sort guaranteed to germinate, the best being from 90 to 95 per cent.

## REMARKS.

7th.—Brilliant day, but very cold; hazy in evening.  
8th.—Dull early, fine bright day.  
9th.—Brilliant all day.  
10th.—Cloudy early, fine bright day, very cold.  
11th.—Nearly cloudless throughout.  
12th.—Cloudy, but a little sun about 2 P.M.  
13th.—Dull and cold, with a little sleet, not measurable.  
Another intensely cold and remarkable week. We have now had a month without single day on which the temperature has reached 45°, and we have had frost not merely on grass but in the air every day since February 18th. The earth temperature is becoming remarkably low; at 1 foot it is only 14° above freezing, and the same low temperature reaches to 3 feet below the surface.—G. J. SYMONS.

## COMING EVENTS

25	TH	Royal Society at 4.30 p.m.
26	F	Spring Show at the Crystal Palace (two days).
27	S	Royal Botanic Society at 3.45 p.m.
28	SUN	3RD SUNDAY IN LENT.
29	M	
30	TU	Spring Show at Westminster Aquarium (two days).

### THE ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW.

**W**E are glad to learn that arrangements have been made on an equitable basis between this Society and the Liverpool Horticultural Association for concerted action, with the object of producing an exhibition of the greatest magnitude in the Botanic Gardens and Wavertree Park of the famous maritime city. That this arrangement will be mutually advantageous there can scarcely be a doubt, for to divide the local resources, great as they are, between two shows within a month of each other would inevitably weaken both. The date may possibly be fully too early for staging in the best condition much garden produce of the Liverpool district, but it is to be remembered that the show is to be regarded as representing the horticulture of the nation, not of a locality. That the skilled cultivators of the neighbourhood will hold their own in many of the classes there is not a doubt; but be that as it may, it is evident a sufficient breadth and liberality of mind exists to welcome the best produce from wheresoever it may come. The Liverpool gardeners show their strength in the decision lately arrived at, and the status of their Society will not suffer by this alliance with the Royal in promoting high culture in British gardens.

We have before us a report of a special general meeting of the Liverpool Horticultural Association, convened by the requisition of thirty members, to consider the advisability of the amalgamation in question, in order to render the exhibition to be held towards the end of June a great success. The meeting was held in the Nisi Prius Court, St. George's Hall, at eight o'clock on the evening of the 18th inst., Mr. White, Vice-President of the Association, presiding. The Court was crowded, probably 150 to 200 members being present. It may be well to state that the Committee of the Association had decided by a majority of two not to accept the terms of the Royal Horticultural Society, but to hold their Show as usual in Sefton Park or elsewhere towards the end of July. The terms of amalgamation, as stipulated by the Royal, were £250 for 3500 tickets—namely, 1500 for the first or second day, and 2000 for any other day. Mr. White, after reading the circular and explaining the objects for which the members were called together, called upon Mr. E. Bridge, the Secretary, to read the correspondence that had passed between the officials of the Royal and those of the Association. Mr. W. Bardney then submitted a resolution to the meeting to the effect that the Committee accept the terms of the Royal Horticultural Society to pay the sum of £250 for 3500 tickets, admitting the subscribers on the first and second day, the Association not being held responsible or liable in any way for any further amount than that specified for the tickets. "The feeling," continues the report, "was somewhat strong against the idea of the ordinary members, which are nearly all gardeners, not having admission till after the second day. Mr. Bardney stated that he thought the officials of the Royal would not treat them less advantage-

ously than the Manchester Society, who always make provision for the admission of gardeners on the first day for a small sum. He believed they would grant the tickets for the sum named, even if they did not admit the ordinary subscribers towards evening on the opening day, which he and several of his supporters believed would be the case, on the ground that it could make very little difference to the Royal what day they admit them, for there is plenty of room; and if announced that they would admit them on the first day the Royal would secure the united efforts of all members of the Association."

Mr. R. G. Waterman seconded Mr. Bardney's resolution, which was ably supported in speeches by Messrs. R. W. Ker, J. Cowan, and J. Gore. An amendment was submitted to the contrary; but, though most ably advocated, it only secured thirty-nine votes, Mr. Bardney's resolution being carried by an overwhelming majority. The meeting occupied nearly two hours, and the clapping and cheering was most enthusiastic when it was perceived the proposition had been so favourably received.

We have received a letter from a member of the Liverpool Association, who appears to regret the decision arrived at on the grounds that each member ought to have received notice of the meeting; that a later fixture would have been more seasonable, and that the admission of members on the "third and fourth days" of the show is not an arrangement that can be regarded as satisfactory.

It is only necessary to deal with the last objection, and this we shall do in the expression of a hope that the members of the Liverpool Association will be treated in the most liberal manner that is practicable. We venture to suggest that as there will be more or less of confusion on the first day, that though honorary members might be admitted then, early in the morning of the second would be the best time for gardeners to enjoy the show—say from seven to ten o'clock, if such an arrangement could be made, or some other by which they could have a "quiet look round" before the admission of the general public—a plan which has answered well and given much satisfaction at great exhibitions we have seen in Scotland, but as the judging was completed by about eight o'clock in the morning, early admission was granted to gardeners on the first day, which obviously cannot be done at Liverpool. We have no doubt, however, that everything that can be done will be done both in the interests of the honorary and ordinary members of the Liverpool Association, and as conducive to the success of the great undertaking.

### HINTS ON FIRING.

SEVERE and prolonged cold weather has exercised all the ability of growers to protect their plants and secure an atmosphere best calculated to enable them to resist the debilitating influence of the increased fire heat. The temperatures required in the various houses are a source of much anxiety to the gardener at all times, as so much of successful practice depends upon their maintenance, especially at night. The duty of stoking falls in most private places to the young gardeners, and very advisedly, as no man will ever be competent to take charge of a collection of plants, or have charge of structures in which forcing operations are carried on, unless he thoroughly understands and has practical experience of the duties of stoker. In this respect the nurseryman has a great advantage over the private grower. The former has such an extent of glass that he finds it suits his purpose best to employ a professional stoker. These experts not only maintain the exact temperatures ordered by the grower, but so regulate the fires by the variations of the external temperatures that they in the course of a season save much fuel.

Respecting night temperatures the stoker almost always errs on the high side—that is, if we are forcing Vines, and the order is to keep the temperature at 60° on cold nights, or

65° in mild weather, it is common to find it 65° on the cold, and 70° on the mild night. When the weather is uncertain this is perfectly justifiable. As a rule, however, the temperature should be maintained at that ordered, and at making-up time the fire will, if properly attended to in the earlier part of the evening, be sufficiently burned down to be easily cleared of ashes and clinkers. On the other hand, if the fire at leaving off work time has been banked up so as to last until ten o'clock, in order that pleasure may take precedence of duty, then it is likely we shall find something beyond the 5° extra, the temperature corresponding to the day maximum with the fire low or nearly out. Fires ought to be so attended to through the afternoon and early evening as to be ready to act upon the temperature upon any change in the weather between leaving off time and the final banking up at ten o'clock, and the stoker must take a forecast of the weather prior to seeing to the fires.

A good stoker invariably develops into a good gardener, inasmuch as stoking requires unremitting attention, constant observation, forethought, and sound judgment. Under ordinary conditions the influence of solar heat will be spent by leaving off time, the temperature having settled down to its ordinary height from fire heat, and the heat subsequently, or through the night, will be dependant upon the stoker. If the night be dull the fire must be such as to maintain the temperature steadily as required, needing only freshening if frost set in, or snow or rain fall. Firing by fits and starts is only wasting fuel, and a certain method of insuring disaster in culture. Starting the fire on an appearance of frost is right, but it is highly prejudicial to keep it going briskly until the pipes are as hot as possible, and the temperature made to rise rapidly, for the simple reason that the heat will increase afterwards and the night temperature be too high. Allowance must be made for the continued action of the fire, and the latter regulated accordingly. Some start fires and leave them until they are burned low or almost out. Then the fire takes time to get up again, and begins to act at a time when the temperature should be falling, the house being 5° or 10° warmer than is necessary in the morning.

A very important matter in stoking is the regulation of the draught by means of the damper. There is no question of the importance of having a damper in the flue, beyond the furnace or flues that are used to give direct or indirect heat to the boiler. There should be the usual furnace door, with half-inch iron plate with its inch cavity to keep the heat of the furnace from being cooled, as it would were there only the outer plate or door radiating the heat from its highly heated surface. The inner plate is usually pierced with some half-inch holes, which prevent its being highly heated and keep it from warping. A hole or two in the outer plate may or may not be of consequence; if there be they should have slides for closing or opening them at will, but I do not see that we want air by the furnace door. The ashpit door must of course have a ventilator in its centre, as some air is essential for even slow combustion, and by these means we can regulate the draught. Nevertheless, we need something to keep the heat about the boiler, and a damper in the ascending shaft or chimney is advisable, so that by regulating the current of air entering by the ashpit door, whether these are folding or sliding, and keeping the heat from passing up the chimney, we obtain complete control over the draught. The damper must be used according to the weather expected. If at banking time there are signs of frost the draught must be regulated according to its probable intensity, whilst for rain it should be regulated as for 5° of frost, and in case of snow being likely to fall calculate and regulate as for 10° of frost. Always allow for the external temperature descending through the night. If it does not do so the heat in the morning will be too high, but it must be remembered that for at least half the night the temperature was right.

In the morning whilst the fire is low make a thorough clearance of ashes, clinkers, and if need be of soot from the flues, the aim always being to secure a clean implement,

which works more easily and effectively than a dirty one, besides being cheaper or more economical. It is essential that the fire have a clean course, air having free access to the furnace, and an equally free exit for the products of combustion. Nothing indicates the character of the stoker so much as the way the stokehole is kept. If slovenly the boiler and everything in connection with it is out of order, the heat irregular, and great waste of fuel occurs. A good stoker will raise the heat in good time in the morning. He will be at work betimes, and at eight o'clock in winter can have a temperature little short of that required as the day maximum from fire heat, and whether there be sun or not a good long day is secured. It is no use forcing growth in the dark, for we cannot then obtain elaboration of the sap or solidified, short-jointed, sturdy, fruitful growth. A forecast will be taken of the coming day as of the night. If likely to be a dull day the fire will be so regulated as to maintain a steady and progressive heat until one or two in the afternoon, then the tendency will be downwards though steadily, the chief thing being in dull days to maintain the growth already secured healthy without any great addition until there is sun and light to effect its proper maturation. If likely to have some clear weather alternating with cloudy the fires are kept steady for the day. What advance is made is due entirely to sun heat; greater facilities are afforded for ventilation without lowering the temperature, and the essential of elaboration is secured in a most satisfactory manner.

On bright and frosty mornings small and sharp fires should be the rule, so that by the time the sun makes itself felt in the houses the fires are so low as not to afford much heat, and excessive ventilation to prevent the temperature rising too high will be avoided. The fires on such occasions will be started sufficiently early in the afternoon that by the time the sun's power is waning the heat given out by the pipes will prevent a hasty depression, yet aiding to keep up the temperature, a long day of work being effected, more in the way of elaboration and assimilation being accomplished on such day than in a week of dull weather when the whole of the conditions are artificial. The night temperature after such days will be kept steadily decreasing to its minimum; and if the night be very cold, as is usually the case after a bright day, the temperature may fall 5° lower than the ordered minimum, and instead of this disturbing the chief, his countenance will have the smile of satisfaction, more especially as the heat in the pipes in the morning shows an early rising of the temperature meeting that of the prospective sun heat, giving promise of another long day's work in improving the texture and colour of tender foliage, which cannot be effected when deprived of the fruitful influence of the sun.—G. ABBEY.

## REMARKS ON SOWING VEGETABLE SEEDS.

(Continued from page 207.)

BRUSSELS SPROUTS AND EARLY BROCCOLI.—It is hardly possible to err in sowing the former too early in the year, especially when no heat is available. Unless the plants are finally planted out before the majority of the various sorts of Broccoli, Kales, and Savoys, they rarely grow to a good size or produce an abundance of close hard sprouts, and unless sprouts are very firm they do not possess that delicious marrow-like quality for which they are so much valued. The growers for market frequently sow the seed in the open as early in February as possible, protecting the young seedlings during severe weather with straw litter, but I am afraid they will have had a difficulty with their seed beds this season. Even when they are somewhat late in planting, their plants, owing to the firmness of ground and exposed positions, usually yield good gatherings, the only difference being that the plants, perhaps, are 2 feet instead of 3 feet in height, which makes a material difference in the value of the crops. Private growers can easily raise sufficient plants for their garden, as a pinch of seed may be sown either in pots, pans, boxes, or frames, little or no heat beyond the protection of a frame or house being necessary. The plants ought to be well exposed before they become drawn, and when fairly strong should be pricked out on a warm border about 4 inches apart

each way. If properly preserved from slugs and slightly protected with branches of evergreens they soon grow to a good size, and when they touch each other may be finally transplanted with a trowel. Some dispose them between rows of Broad Beans, but the latter are apt to weaken the Brussels Sprouts, and I recommend that nothing but either Early Ashleaf Potatoes, early Turnips or Lettuces be grown between them, the crop being of too much value to justify incurring any risks. The rows may be 3 feet apart, the plants in the rows about 2 feet asunder. The Aigburth is a very reliable sort, but is rather too coarse for connoisseurs, and for home use we prefer either Sutton's Exhibition, Webb's Matchless, Veitch's Exhibition, or Ne Plus Ultra, the latter being exactly similar to Northaw Prize—a fact which Mr. Merritt the raiser of the former may be able to account for. The only Broccoli that need be sown early, or in the same manner as the Brussels Sprouts, is Veitch's Autumn Protecting. We grow three times more of this valuable sort than of any other Broccoli, and, with a little attention in the way of lifting and storing in vineries or pits as fast as the heads become near the size of a cricket ball, it yields a supply from October till February. Snow's Winter White when sown early grows to a great size, but produces few or no good heads, and monstrosities we have no room for. Late in April or early in May is quite soon enough to sow this popular but somewhat over-rated sort.

**CAULIFLOWERS.**—Autumn-sown plants are very scarce this season, and in many cases it is advisable to sow seed in mild heat of Extra Early Forcing, as well as either Dwarf Erfurt or Early London and Veitch's Autumn Giant. The plants of the former may be potted and eventually planted under hand-lights or in a large rough frame, a little protection bringing them on rapidly; the later sorts to be pricked out on a warm border or in boxes, and placed under glass if need be till large enough to plant out. Fortunately Broccoli appears to be but little injured; and later on, if such sorts as Sutton's Late Queen, Ledsham's Latest of All, Model, Cattell's Eclipse, and even Leamington, are carefully lifted and bedded in thinly on a north border, a little good manure being firmly placed about the roots, the supply of white and very good Broccoli can be maintained, it may be, till the middle of June.—W. IGGULDEN.

#### MUSCAT OF ALEXANDRIA AND BOWOOD MUSCAT.

"G. G." confirms the idea that I at first formed regarding the setting of the Bowood Muscat. Evidently it was set before the boiler broke down, and though the heat does not seem to have been satisfactory for some time previous to the breakdown of the boiler, it may be assumed that it would be considerably greater than after that breakdown and during the time the Muscat of Alexandria was in bloom.

The Muscat of Alexandria having to face a time of trial, no doubt failed under that trial, but would not Bowood have done the same? I have to thank "G. G." for his offer of eyes of Bowood, but I may say I am not sufficiently convinced of its superiority or difference from Muscat of Alexandria to tempt me to break a rule laid down some years ago—viz., never to take young Vines or Vine cuttings from anyone, for fear of getting phylloxera. Not that I would for a moment suggest that "G. G." may have any such pest about his place, but simply because I am not inclined to break the rule laid down and hitherto strictly observed.

Muscat of Alexandria has for so long done well in regard to full fruiting and good setting that I am not tempted to wish to change it. The time and care required in order that a good set may be obtained are well repaid, and nothing but mismanagement or inattention can be blamed when a failure of Muscat of Alexandria, in regard to setting, is chronicled.

Of course under such trying circumstances as "G. G.'s" Muscat of Alexandria was, little wonder need be expressed at its failing to set. Give it fair play and good treatment, and Muscat of Alexandria will set well, swell well, and keep well, and failure in regard to it can generally be traced pretty easily to some cause. I am not disposed to doubt "G. G." when he says his Bowood produces bunches as freely as any of his thirteen varieties, and is only inferior to four in regard to its setting qualities, but I claim for Muscat of Alexandria equally free fruiting, and, when properly attended to, also equally good setting qualities. There will evidently always be two parties in regard to the question of the distinctness of Muscat of Alexandria and Bowood, and no doubt both are, and always will be, equally strongly convinced that they are right. "When doctors differ, who shall decide?"—A READER.

#### HINTS ON ORCHID CULTURE.

(Continued from page 215.)

**WATERING, SYRINGING, RESTING.**—Few plants that are not aquatics require so much water as Orchids both about their roots and in the atmosphere, and therefore the supply of moisture is an important operation. Healthy Orchids when growing freely can scarcely have too much water, and during the summer they will need attention

twice a day independent of damping the paths and stages, or syringing. In the winter and during the resting period of Orchids, whether terrestrial or epiphytal, the supply must be greatly reduced for all except *Odontoglossums*, *Masdevallias*, and others which continue active throughout the year. Non-pseudo-bulbous Orchids must also have a more liberal supply of water than those with pseudo-bulbs, which serve as storehouses of nutriment. In the summer and growing season the material on the shelves and the paths must be kept well moistened, and in cool houses shallow tanks should be provided at the sides of the paths. For supplying the plants and syringing rain water is the best, and it must always be used about the temperature of the house. Hard water should be avoided except for damping purposes, as though lime is not injurious to some Orchids it disfigures the foliage. Baskets and blocks can be dipped, but this must be carefully done with the former, or the drainage may be disturbed. There is some difference of opinion respecting the beneficial effects of syringing, but the majority of cultivators have proved its usefulness, and in some large trade establishments the plants are syringed most liberally, ordinary watering-cans being seldom used. Morning and evening syringings in the spring, summer, and autumn are beneficial to growing Orchids, but care must be exercised to keep the water off the flowers, and as much as possible off young tender growths, particularly those of *Læias* like *L. purpurata*; while in the winter it should be discontinued, especially when the weather is severe. At St. Albans a simple and labour-saving mode of damping the houses is adopted, which is, however, only suitable for large establishments. Under the stages and along the paths in every house are taken two or more pipes 1 inch in diameter, which are perforated at short intervals and connected with the main supply, so that by turning taps in convenient positions the whole house or any portion can be quickly damped with little trouble.

The atmosphere of Orchid houses must be constantly moist, and in hot weather this can only be effected by a frequent and liberal distribution of water upon the paths and stages. A useful instrument for determining the amount of moisture in the air is the hygrometer, consisting of two thermometers graduated exactly alike, with small projecting bulbs. These are affixed an inch or two apart to a porcelain or other frame, and the bulb of one is connected by a little syphon of cotton, or lamp-wick, with a small bowl kept constantly filled with water. The evaporation of water from the latter, termed the wet bulb, by the extraction of heat, causes the mercury to fall, and by comparing the temperature thus registered by that shown in the dry-bulb thermometer, which indicates the temperature of the house, it is seen at a glance whether the air is dry or moist. When saturated with moisture the mercury in the two tubes will stand at the same level, and the drier it is the greater will be the difference between them. This simple instrument can be easily constructed if two evenly balanced thermometers are obtained, but they can now be purchased very cheaply, and should be employed wherever Orchids are grown in quantity. In fig. 42 is represented a convenient hygrometer from Messrs. Negretti & Zambra, Holborn, but there are several other forms, some being constructed with a mechanical arrangement and dial to show the condition of the air.

Fig. 42.

Deciduous terrestrial Orchids require a decided period of rest, during which water is either entirely withheld or is given in very small quantities. Evergreen pseudo-bulbous Orchids must never be "dried off," but their rest consists in lessening the heat and moisture, though in the case of the *Odontoglossums* the supply must always depend upon their condition. Deciduous pseudo-bulbous Orchids also require a period of rest, but water must be given in sufficient quantities to prevent shrivelling.

**VENTILATING AND SHADING.**—In warm moist districts ventilation can be given much more liberally than in cold exposed or dry situations, and to these varying circumstances are due the different opinions on the advantages to be derived from free ventilation. Wherever the climate is suitable and when the weather is favourable there is no question that most successful results are obtained by admitting air freely not only to cool-house but to tropical Orchids, and I have seen the late Mr. Percival's fine *Cattleyas* being absolutely blown about by brisk sea breezes, and Dr. Paterson in warm Bridge of Allan has adopted a similar system with equal advantage. For cool Orchids a liberal supply of air during the greater portion of the year is essential, and in one of the largest trade establishments small wooden pegs are placed between the laps of the glass, so that there is a space of an eighth of an inch between each two panes, and a similar space at the bottom of the rafter. In the same place the walls are constructed so that there is a moveable half-brick at the end of each

whole brick just below the side shelf and opposite a hot-water pipe. These act as plugs, which are removed in spring immediately the frost has departed and are not put in again until autumn, thus affording a free admission of air both day and night. This is only noted as an example of what can be done, for in ordinary establishments a piece of board 8 or 9 inches wide, sliding in two grooves outside the house opposite the pipes, is sufficient for ventilation beneath the stages, though iron or wooden hinged shutters are also employed. In one place I have seen the following method adopted: a channel runs down the side of the path under the pipes, communicating with a small chamber outside the house covered with a grating. The channel opens into the house by several apertures, which can be opened or closed by small lids, and the cold air thus admitted ascends directly to the pipes, being partially warmed before it comes in contact with the plants. The outside grating can also be covered when necessary. Roof ventilation can be accomplished in various ways according to convenience, but for all warm houses, especially in cold bright weather, it is advisable to have pieces of tiffany stretched across the opening to break the force of the cold current. During the winter whenever the wind is keen or frost severe never ventilate, and in very hot dry weather it is better to shade well, employ no fire heat, damp liberally, and ventilate but little. Without artificial heat the temperature of all but the typical cool houses may be allowed to rise considerably above the maximum temperatures given in the table without danger if water be abundantly supplied. For this reason the houses may be closed at 3 to 5 P.M. according to the season and the weather, but a little all-night ventilation in the height of summer will not be hurtful to tropical Orchids, and for the others it should be the rule at that time of year.

The ordinary roller blinds are the most convenient for shading purposes, as they can be quickly run down or up according to the weather. A very convenient form of blind is the Parisian chain blind, which is formed of narrow strips of wood a short distance apart, so that, while effectually breaking the force of the sun's rays, they do not darken the house. These are giving satisfaction in several Orchid-growing establishments. For *Odontoglossum* houses in sunny positions permanent shading is sometimes applied to the glass, and the best I have found for the purpose is prepared in the following way: 1 lb. each of tallow and flour and  $\frac{1}{2}$  lb. of whiting are mixed together with cold water and sufficient Brunswick green to tint it as required, and the mixture is then warmed in a pail before applying it to the glass, which should be done when the sun is shining. This lasts well and does not render the house too dark if put on thinly. This will only be needed in the spring and summer, and houses with a north aspect will not require it. Some Orchids require more shade than others, and those like *Cypripedium* or *Phalænopsis* should be given the shadiest side of the house. Artificial shading should, however, only be employed in very bright weather and in the hottest part of the day to prevent the temperature rising too high, as too much shade weakens the plants and prevents their growths ripening.

**PROPAGATING.**—Few Orchids can be quickly increased by any artificial method of propagation, and it is to this fact that hybrids raised in this country so long maintain their value, whereas an introduced species may be scarce and high-priced for a time, and then perhaps a fortunate collector sends home a large shipment and the value falls immediately. Amateurs cannot depend upon propagation to add much to their stock, as in most cases it takes too long, and it is far better to purchase small established plants, which can be had much cheaper than formerly, or even to procure imported plants. It may happen, however, that a particular variety is possessed that it is desirable to increase, or perhaps it is wished to try a few experiments, and in either case some hints will be needed as to the modes to be adopted. In the first place do not commence experimenting with any valuable plant; gain a little experience first with some of little consequence, for Orchids are easily injured by any process of division unskillfully performed, and some seem to object to it altogether. Strong healthy examples only should be selected, and even these must be carefully treated afterwards. The latter remarks especially apply to the method adopted with many Orchids having short ovoid pseudo-bulbs of the *Cattleya* or *Odontoglossum* types—namely, cutting between the pseudo-bulbs and through the rhizome, so as to retain some roots with each. The safest plan is to leave these in the pot for some time until it is seen that fresh growths are coming from the divided portions, when they can be potted or otherwise as is most convenient. This plan is also adopted when it is desired to produce what are termed “back growths” to make a better specimen, as old pseudo-bulbs will often form growths when thus treated, greatly improving the appearance of a plant. *Lycaste Skinneri* is readily increased in this way, and old pseudo-bulbs can be separated and potted singly, giving them little water until a bud starts from the base. Most hardy tuber-bearing Orchids can be increased by division in autumn after their stems are dead, or preferably in early spring before growth starts.

For many exotic, deciduous, or evergreen Orchids with long cylindrical pseudo-bulbs another system may be tried, as, for example, with *Dendrobium nobile* and species of similar habit. Of these, any pseudo-bulbs that have flowered but are not old or shrivelled may be cut from the parent plant and laid lengthwise in moss, secured to a block or in a pan, or cut into lengths of about 6 inches and inserted in pots of moss kept constantly damp. *Dendrobium nobile* produces young plants from the nodes very readily when treated in this way, and I have reared a dozen from one pseudo-bulb; but usually the plants are chiefly formed in the upper portion, and are occasionally so produced without removing the pseudo-bulbs from the old plant, while some prefer pegging them down round the pot in which they are growing, though this is sometimes inconvenient. *Thunias* are propagated by cuttings in the same way as mentioned for *Dendrobiums*, but sand should be substituted for the moss. The best time for such operations is early in the spring, as it gives the young plants so obtained a better chance of becoming established before winter, which in our climate tries them severely even with the best care. When separated or potted singly water must be supplied in small quantities until some progress is observed, when they may be gradually accustomed to the treatment given to the other plants. *Vandas*, *Aerides*, and others of similar habit can be increased by taking off side breaks or the tops of the plants with a few roots attached and potting them in moss, and when the former become too tall they are occasionally reduced to more convenient size in this way; but they should receive very careful attention for some time afterwards in shading and keeping them close. *Cypripediums* are easily increased by division in the ordinary way, and skilful growers do not hesitate to practise this with the most valuable hybrids.

What may be termed natural methods of propagation can be taken advantage of with Orchids which produce young plants upon their stems or pseudo-bulbs, like several *Epidendrums*; others, as the *Phalænopses*, particularly *P. Lüddemanniana*, occasionally bear plants on their flower stems or on their roots, as with *P. Stuartiana*; while others, like *Calanthe vestita* or the *Pleiones*, produce young plants on their old pseudo-bulbs that can be separated and grown on as advised.

If the ordinary methods of propagation are slow, raising Orchids from seed is a still slower process, and it cannot be recommended except for those who are interested in obtaining hybrids. It requires much patient waiting, constant attention, and perhaps after years of this care some enemy may devour the plant; it may die some hot day from a little neglect in watering, or it may “damp off” in a dark cold winter. Independent of these difficulties seed-bearing is exceedingly weakening to Orchids; a weak plant may be killed and a strong one so injured that it will take several seasons to recover its usual condition. Even producing flowers alone is weakening, and young delicate plants should not be allowed to produce many or retain them long; in fact it is better not to permit any plant in doubtful health to flower at all. Then it is difficult to insure the proper maturation of the seed-pods, and even when these develop and ripen satisfactorily they are occasionally found to contain no seeds, or only imperfect rudimentary bodies that will not germinate. Mr. Harry J. Veitch in his paper read at the Orchid Conference gave some interesting particulars concerning the time the capsules take to ripen, from which the following are selected as examples: *Calanthe*, three to four months; *Masdevallia*, four months; *Zygopetalum Mackayi* crossed with *maxillare*, six months; *Phalænopsis Schilleriana*, six months; *Lælia purpurata*, nine months; *Cypripedium insigne*, ten months; *C. Spicerianum*, eleven to twelve months; *Cattleya labiata* and others, eleven to thirteen months; *Anguloa Clowesi*, *Chysis bractesceus*, *Dendrobium aureum*, *Maxillaria Harrisoniana*, and *Odontoglossum maculatum*, twelve months. Considerably longer periods are required to bring the plants from the germinating to the flowering stage, as the undermentioned facts will show from the same authority as the preceding. *Dendrobium aureum* crossed with *D. nobile*, three to four years; *Phaius* and *Calanthe* about the same time, the seed of the latter germinating in two to three months from the time of sowing; *Masdevallia* and *Chysis*, four to five years; *Cypripedium Schlimi* crossed with *longifolium*, four years; the reverse cross, six years; *Zygopetalum maxillare* crossed with *Mackayi*, five years; the reverse cross, nine years; *Lycaste*, seven to eight years; *Lælias* and *Cattleyas*, usually ten to twelve years, but some have taken much longer, as *Lælia callistoglossa*, which was sown in 1858 and flowered in 1877, the quickest being *Lælia triophthalma*, sown in 1875 and flowered in 1883.

Seed must be sown immediately it is ripe, but it should be done if possible in the spring or early summer, as it is much more likely to germinate then than in autumn or winter. It is usually sown upon living moss in pans where other Orchids are growing, or upon blocks of wood, Fern tree stems, the sides of pots, and various other ways; but the first named is the best, and the chief object is to keep the

moss constantly moist, disturbing it as little as possible, until the diminutive plants have made some progress and are forming their leaves. They may be then very cautiously removed and placed in thimble-pots of moss plunged in a larger size, the space between the two being filled with moss kept regularly moist. The utmost care will be needed in this respect, and the seedlings must not be exposed to the direct rays of the sun or draughts of cold air. After some years of trouble the cultivator may possibly be rewarded by seeing a novelty of great merit flower. Amateurs must not be discouraged by these difficulties, but all who have the time should try some experiments, for though wonderful progress has been made in hybridising by Messrs. J. Veitch & Sons, there is still an ample field for investigators, and many gentlemen have turned their attention to the matter in recent years. In any attempt of the kind care must be exercised to prevent the intended seed-bearer being fertilised from any other source, both before and after the desired cross has been made. This may be effected by tying a piece of gauze round the flower when it is expanded, also removing its own pollinia.—AN AMATEUR.

(To be continued.)

### SHRUB PLANTING IN SPRING.

NURSERY plants received at this time require very great care in order to assure the plants taking to their new quarters. In remarking on this question, it must be understood that the soil here is a very poor one, much of it gravelly and sandy, while dry east winds prevail during the spring months. If the plants arrive from a nursery, perhaps after a few days removal it will be found that wetting the roots and top with water and keeping them covered with mats or straw until required for planting will refresh them very much. It is better to do this than to lay the plants in soil. Planting must be taken in hand as quickly as possible. In our poor soil it is found of much advantage to plant in some light material. Leaf soil is very good for this purpose, and so is any compost formed from decayed vegetables and other refuse from the garden. It is in all cases better to plant deeper, and the more sandy the soil may be the deeper should the roots be placed. Especially is this necessary with members of the Pine tribe, Cypressess, &c. All the plants have basins left for necessary water as required, and in the case of shrubs of extra value a mulching of dung repays the outlay.

Then with regard to watering. Enough should be poured into each basin to soak through and through the contents of each pit; and this ought to be done as soon as the shrub is planted and secured to a stake. In an hour or two thereafter a little dry soil scattered over the surface acts as a good conservator of moisture. Both deep planting and watering of newly planted shrubs are condemned as being injurious to the plants, and I have no doubt that is so under certain conditions, but in our circumstances, and which are not peculiar, I have found that both are points that are necessary in open soil. In heavy soil deep planting would of course have a very different effect. During any period of drying weather a weekly application of water is an absolute necessity, and care must be taken that the plants do not suffer before water is given. I have transplanted shrubs and Conifers in autumn which had been received the spring of the same year in very poor condition, and under treatment as described they can be removed with good roots and require no further attention after. On the other hand, shrubs left to themselves, though they may and do struggle through, are often so severely damaged that it takes years before they are established.

Reverting to the question of laying in shrubs which come from a distance, my opinion is that the practice is not beneficial to the plant. The exact reason why shrubs should resent being planted in soil for a few days or weeks, and then lifted and planted out permanently, is not quite clear to me; but I have no doubt that they do resent it, as the effect has often been forced upon me. Anyone who has work of this kind in hand may easily prove to his own satisfaction the difference resulting from, on the one hand, covering shrubs completely with straw after moistening them, and, on the other hand, covering the roots with soil until they can be planted.

Shrubs which give way during the early summer may in many cases be saved from death by cutting over the plant a few inches above the surface of the soil. If any of the roots are fresh and the planting been sufficiently deep, shoots will be formed before the end of summer, and the foundation of what may be a good specimen in a few years will be laid. It may be noted that the present is a very good time to get large shrubs prepared for removal at some future time. This is done by marking off the size of ball that it is wanted to remove with the plant in the form of a square; then cut down a trench on each side of the square, leaving the corners untouched. If the roots are few and

large, it may be necessary to complete the work by cutting across the angles at each corner the next year, but generally the one root-pruning will do. If the plant be of value the trenches should be filled with light material pressed firmly down, and more young roots will be formed, and that more rapidly than in cases where the soil taken out is merely returned. It may be pointed out that square balls are most easily removed, as boarding can be fitted down each side, and the ball, as it were, enclosed in a box.

To those who have not tried summer planting, it will be of interest to know that blanks in conspicuous positions arising from deaths in spring-planted shrubs may be made up at any time in the summer months, provided the work is undertaken in dull weather and the plants removed with a ball of soil moistened and kept moist for awhile after replanting. For this purpose a few reserve plants put into a bed of light material in which they can make a ball of roots quickly is of much service. Failures of all kinds are best mastered and got rid of as quickly as possible, and the matter under review is certainly no exception to that rule.—B.

### SALVIA BICOLOR.

THE genus *Salvia* is best represented in our gardens by the tender and half-hardy species, of which *patens*, *splendens*, *involucrata*, and

Fig. 43.—*Salvia bicolor*.

*gesneræflora* may be taken as illustrations. The hardy section includes, however, many desirable species, of which the *S. bicolor* here figured is an example.

Its blossoms taken individually are, perhaps, less attractive than those of the now common *S. patens*; but, on the other hand, they are far more abundantly produced, and are much less fugacious, remaining expanded several days after their full development. In any moderately good soil the plant attains the height of 3 or 4 feet; and clothed as it is with very handsome foliage, an established specimen forms, when in flower, an exceedingly interesting object. Its blooming period extends over a period of two or three months if prevented from ripening seed.

It is, moreover, perfectly hardy, and requires, therefore, none of the attention necessary to preserve its more tender congeners from the rigours of our winters. So numerous, in fact, are the claims of the *Salvia bicolor* to attention, that it seems surprising that this species should be comparatively so little known. It was first introduced into this country as early as 1793, but appears to have been almost entirely lost until its re-introduction about 1845 from the north of India by Messrs. Standish and Noble, Bagshot.

*Salvia bicolor* may be readily increased either by division of the roots in spring or by seed, which generally ripens freely, but which must be gathered just before it is fully mature, or, like that of the *S. patens*, it falls from the nodding calyx.

It should be sown on a gentle hotbed early in spring, and the seedlings, when an inch or two high, must be transferred singly to small pots of light soil, and subsequently shifted into larger, until the plants are fit for turning into the borders in May. They will usually flower the first season, as is the case with nearly all the *Salvias*, though not, indeed, so early as older plants. In the absence of a hotbed we have no doubt that seeds would readily vegetate if sown in a warm border about the end of April, especially if assisted by a hand-glass, or protected at night from frost and snails by having a flower-pot turned over them.

Although *Salvia bicolor* has been found, as we have already intimated, in the north of India, it appears also to be a native of Barbary, from which country it was first introduced. This plant must not be confounded with the blue-and-white variety of *pratensis*, commonly sold under the name of *bicolor*.—W. T.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 23RD.

HYACINTHS, Daffodils, and Orchids were plentifully shown in the conservatory at South Kensington on Tuesday, and collectively they formed a very interesting exhibition, but the Hyacinths were not so numerous as usual, the Daffodils occupying much the greater space. Amongst these the members of the Narcissus Committee found much to occupy their time and attention, while the orchidists were similarly pleased with the display of their favourites. Of the latter Baron Schröder's magnificent *Dendrobium crassinode-Wardianum*, and handsome specimen of *Cattleya Lawrenceana*, with Messrs. W. Thompson's beautiful example of the hybrid *Dendrobium Leechianum*, were the chief attractions, though several other notable plants were exhibited by continental growers. Messrs. J. Veitch & Sons' and Messrs. J. Cutbush & Sons' Hyacinths included admirable specimens of those useful bulbs, the Daffodils being from Messrs. Barr & Son, T. S. Ware, and Collins Bros. & Gabriel. During the afternoon there was a good attendance of visitors, as the day proved very fine and exceedingly mild.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq., in the chair; and Messrs. Arthur W. Sutton, W. Warren, G. T. Miles, J. Willard, Charles Ross, G. Norman, P. Crowley, Harrison Weir, T. B. Haywood, William Denning, G. Bunyard, J. Woodbridge, R. D. Blackmore, H. J. Veitch, F. Mason, and Dr. Robert Hogg. This Committee had but little business to execute, as there were few contributions. Mr. Lye, Market Lavington, sent tubers of Potato King of the Russets, which has been tried at Cbiswick, and a seedling from a cross between Old Fortyfold and Schoolmaster, a round variety with purple eyes, which was referred to Cbiswick for trial. The same exhibitor also had samples of a seedling Onion from Golden Gittau and White Spanish, for which a letter of thanks was accorded. Mr. J. Walker, Pomona Farm, Withington, sent a seedling Apple that was passed. Messrs. Foster and Pearson sent samples of their ventilator previously noticed, and Mr. Horley, Toddington, Beds, had a specimen of a neat and simply constructed hand-light. A meeting of the Fruit Committee is to be held at Cbiswick on Tuesday, the 30th inst., for testing Potatoes.

FLORAL COMMITTEE.—Present: James O'Brien, Esq., in the chair, and Messrs. E. Hill, H. M. Pollett, John Dominy, Thomas Baines, R. Dean, W. Holmes, James Walker, H. Herbst, H. Bennett, W. Bealby, John Laing, W. H. Lowe, Amos Perry, H. F. Lendy, H. Turner, B. S. Williams, and Dr. M. T. Masters.

Orchids.—There was an interesting and beautiful group of these from numerous exhibitors, several novelties being certificated. *Dendrobium micans*, from Messrs. J. Veitch & Sons, is a hybrid between *D. Wardianum* and *D. lituiflorum*, the sepals white, the petals similar, tipped purple, and the lip deep crimson in the centre, a zone of white and a purple tip. Mr. O. Thomas, Chatsworth Gardens, had a plant of *Odontoglossum triumphans*, bearing a spike of fifteen large flowers. Mons. J. Heye, Ghent, sent a plant of *Cypripedium Sallieri*, a very distinct form, the lip and petals of a yellow tint, the dorsal sepal similar, but with small dark dots and a white margin. M. E. Vervae, Mont St. Amand, Ghent, showed plants of *Oncidium fuscum*, *Odontoglossum Pescatorei Vervaeianum*, white, with a few large crimson spots on sepals, petals, and lip; *Odontoglossum mulus*, with a fine spike of flowers, and a curious unnamed *Pleurothallis*, bearing drooping spikes of brown-striped flowers larger than they are usually seen in this genus (vote of thanks). Messrs. J. R. Pearson & Son, Cheshunt, had plants of distinct and pretty varieties of *Dendrobiums Wardianum* and *nobile*, for which votes of thanks were accorded. Mr. E. Hill, gardener to Lord Rothschild, Tring Park, had a plant of the hybrid *Laelia flammea*, with large deep orange-coloured flowers, the lip tipped with bright red (vote of thanks). From the same garden came a plant of *Aerides cylindrica* on a block in a pot, very healthy, and bearing two or three white flowers (cultural commendation). Comte Oswald de Kerchove, Ghent, exhibited a flower of *Lycaste Skinneri alba*, very large and pure white (vote of thanks), Messrs. J. Laing & Co. and B. S. Williams showing plants of *Cattleya Lawrenceana*. Messrs. Sander & Co. showed flowers of *Coleogyne cristata maxima* for comparison with the Chatsworth variety. De B. Crawshaw, Esq., Rosefield, Sevenoaks, exhibited plants of *Odontoglossums crispum*, *hystrix*, and *Ruckerianum*, *Cattleyas Trianae* *Crawshawana* and *Rosa*.

Miscellaneous.—Messrs. J. Laing & Co. had a remarkably strong plant of *Imantophyllum robustum* Mrs. Laing, bearing four trusses of fifteen flowers each, the latter deep orange and very large, with rounded petals (cultural commendation). Mr. R. Dean, Ealing, showed three Primroses—Beatrice, Lilac; Novelty, hose-in-hose, purple; and Brilliant, deep crimson, all beautiful varieties (vote of thanks). F. W. Collinson, Esq., Rookfield, Muswell

Hill, exhibited a plant of *Chrysanthemum* Mrs. Charles Carey, a Japanese variety with flat twisted white florets, and remarkably late (vote of thanks). Mr. Bealby, The Laurels, Roehampton, showed a plant of *Carnation* Madame A. Bernaix, salmon pink flaked with scarlet, large and full. Mr. W. Wood, Eastbourne, sent a variegated *Eupatorium*; and Mr. W. Clay, Kingston, had four highly coloured varieties of *Cyclamens*. Messrs. J. Veitch & Sons had several new Hyacinths besides those certificated, comprising the following:—Blush Perfection, double, white with a pink tinge; Rose Pompon, single, pale blush, fine spike, and large bell; The Bride, single, pure white, large bells and spike; Princess of Wales, single, pink, with strongly recurving petals. Some pretty white *Crocuses* named Mont Blanc, and a pan of *Primula pulcherrima* were also shown.

Groups.—These have been incidentally referred to, and we can only notice them briefly. Messrs. J. Veitch & Sons, Chelsea, had a grand collection of 100 Hyacinths, representing most of the best varieties in cultivation, the spikes large and the colours varied (silver-gilt Banksian medal). Messrs. J. Cutbush & Sons, Highgate, had about 120 Hyacinths, also of many varieties and well grown (silver Banksian medal). The St. George's Nursery Company, Hanwell (Mr. H. B. Smith, Manager), exhibited a superb group of *Cyclamens*, and were awarded a silver-gilt Banksian medal and a cultural commendation for a variety named The Major, with massive white flowers and a crimson throat. Mr. J. James, Woodside, Farnham Royal, contributed a handsome group of his fine *Cinerarias*, the blooms large, beautifully formed, and very rich in colour (silver Banksian medal); and W. Clay, Esq., Kingston, had a fine group of *Cyclamens* (bronze Banksian medal). Silver Banksian medals were awarded to Mr. T. S. Ware, Messrs. Barr & Son, and Messrs. Collins Brothers & Gabriel for groups of Daffodils and other flowers, Anemones of the fulgens type being freely used. A silver Banksian medal was also awarded to T. A. S. Dorian Smith, Esq., Tresco Abbey, Scilly Isles, for a large collection of Daffodils arranged in their several sections, and all gathered out of doors.

## PLANTS CERTIFICATED.

*Hyacinth Queen of the Pinks* (J. Veitch & Sons).—A single-flowered seedling from King of the Blues, the bells large, of good form, and deep pink in the centre of the petals, lighter at the margin. Spike compact and massive.

*Hyacinth Grand Fleur* (J. Veitch & Sons).—A pretty single variety, with purplish rose flowers, a very distinct shade, the bells large and spike compact.

*Dendrobium Leechianum* (W. Thomson & Son).—A fine hybrid, raised by Mr. W. Swann when gardener to W. Leech, Esq., Fallowfield, Manchester, from seed obtained from *D. nobile* fertilised with pollen from *D. aureum*. The crossing was effected in January, 1875, and in February of the following year the seedlings were first noticed, and flowers were first produced in January, 1881. The parents are the same as those of *D. Ainsworthi* and *D. splendidissimum*, but it is quite distinct from both, Messrs. Thomsons' plants being so good and the flowers so fine that a unanimous certificate was granted. The sepals and petals are white, tinged with purplish crimson, the lip over an inch in diameter, of a rich crimson hue, feathering into the pure white margin. Like *D. nobile*, it is very free, and small growths had over a dozen flowers each. An illustration of this hybrid was given in this Journal (page 233, March 23rd, 1882), with the raiser's description of its treatment.

*Dendrobium crassinode-Wardianum* (Baron Schröder).—A supposed natural hybrid, introduced with other *Dendrobiums*, and apparently intermediate between the species named both in flowers and pseudo-bulbs. The latter are 3 feet long, more slender than *D. Wardianum*, with swollen nodes, but less strongly marked than in *D. crassinode*, and the internodes are longer. In the specimen shown the pseudo-bulb had forty flowers, the petals about 1 inch in diameter and rounded, these, with the sepals, being white tipped with soft rosy crimson. The lip is broad and round, golden, with two small crimson dots at the base, a white band, and a pale rose tip. It is a charming Orchid and will probably become valuable.

*Cattleya Lawrenceana* (Baron Schröder).—This fine *Cattleya* has been shown several times without securing honours, and it seems to vary considerably, like others of the genus. The plant shown had twelve flowers, two or three on each growth, the petals  $1\frac{1}{2}$  inch in diameter, and with the sepals of a uniform purplish hue, the lip of an intensely rich crimson colour, and a white throat.

*Odontoglossum Pescatorei Vervaeianum* (M. E. Vervae, Ghent).—A beautiful variety, with well-formed flowers, white, with a few large crimson spots on the sepals, petals, and lip.

*Azalea mollis Lord Shaftesbury* (J. Cutbush & Sons).—A handsome variety, with round well-formed flowers, of a bright golden colour. Very free and useful.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair. Prof. A. H. Church drew the attention of the Committee to a new insecticide, the outcome of a long series of experiments. The preparation in question is essentially a complete and permanent emulsion, in which has been incorporated a large quantity of such oily liquids (including certain kinds of paraffin oil) as destroy the insect-pests of plants. Hitherto the rough methods in use for preparing such emulsions have failed to effect the perfect distribution of the oily matter in the wash, and, in consequence, oily drops of sensible size have spotted and injured the leaves and tender shoots of the plants. The sample exhibited contained two-thirds of its bulk of the above-named oils along with other useful ingredients. On dilution with water no separation of the oils takes place. For very tender and succulent plants half an ounce of the emulsion in a gallon of rain water forms a syringing wash, which proves fatal to green fly, red spider, brown scale, and even mealy bug, without inflicting any injury on the flowers or foliage of the plants to which it is applied. The proportion may be increased in the case of more robust plants—even 4 ozs. to 1 gallon may in some cases be used, though much weaker solutions are in the great majority of cases perfectly effective. The plants if at all delicate should be syringed with fresh water two hours after the insecticide has been applied. By appropriate chemical methods various substances may be introduced into the emulsion in order to meet special requirements of gardeners and Hop-growers. For instance, sulphur, in a free state and yet in a perfectly soluble form, has been added to some of the preparations, and proves to be an efficient pre-

ventive and cure of mildew in Roses. Mr. Church added that he had not hesitated to bring this insecticide before the Committee, since he had no interest, save a scientific one, in the invention.

Mr. Elwes drew attention to the importance of the discovery in its application to the Tea plant, which suffers from blight in the dry season; and on the question being raised as to the paraffin affecting the tea, Prof. Church replied that it had been used in greenhouses on scented plants, as Pelargoniums, &c., and though the smell was perceptible for forty-eight hours it is not permanent.

*Pleurothallus* sp.?—A curious species with striped petals was exhibited by M. E. Vervaeet from Mount St. Amand, Ghent. It was sent to Kew for identification.

*Scoliapus Bigelowi*.—The interesting Californian species was exhibited, the flowers being of rather paler hue than usual.

*Malformed Hawthorn*.—Dr. M. T. Masters exhibited branches which had been arrested in growth and formed short stunted spurs. Mr. MacLachlan remarked that a quickset hedge similarly injured was nearly destroyed. It was evidently due to insect agency.

*Crocuses and Sparrows*.—Mr. MacLachlan alluded to the periodical injury these birds do to Crocuses by biting off the contracted portion of the perianth tube. As the nectar is secreted there, it was probably due to the discovery of this fact by the birds. Mr. Henslow observed that he had not experienced the fact, though both Crocuses and sparrows were abundant in his garden.

*Odontoglossum Rossi*.—Mr. O'Brien exhibited sprays of different varieties of this species, one having white petals and the other mauve.

*Trimorphism in Narcissus triandrus*.—Mr. C. Wolley Dod exhibited specimens showing three different lengths in the pistils—a short, medium, and long-styled form, as in *Lythrum Salicaria*, the short-styled form occurring 20 per cent. of flowers examined; the mid-styled form 10 per cent., while the more usual condition is to be long-styled. In the var. *N. t. pulchellus* the style is always longer than the stamens, and the tube of the perianth is also longer than usual. The short-styled form was received from Oporto. In all cases the flowers appeared to be protandrous.

*N. Henriquesi*.—He also showed a specimen of this plant with no tube to the perianth, probably due to the arrest of the receptacular tube. In reply to Mr. Elwes, he remarked that the bulbs were scarcely hardy, and die if the plants be allowed to seed; and that they must therefore be raised from seed, when they will flower in the second year.

*Camellias and Frost*.—Hon. and Rev. J. T. Boscawen exhibited single Camellias which had lately blossomed in the open, and leafy branches, showing how the leaves of 1885 were perfectly green and untouched by the frost, while those of 1884 and 1883 were browned to various degrees; but those of 1882 on the same branch were perfectly green. The branch was from a bush that had never received direct sunlight.

## CHRYSANTHEMUMS.

### TRAINED SPECIMEN PLANTS.

NEVER before were the Chrysanthemums so well or widely cultivated as at the present time, and it would be almost impossible to write anything that is really new in their culture, yet I find many amateurs need information, hence I give a few brief remarks on a system I have practised with very good results.

Supposing that large trained plants are wanted for exhibition or home decoration, I advise those who have plants that were last year grown for specimen blooms—i.e., with an upright stem—to cut them down to within 6 inches of the surface, and place them where the temperature did not fall below 50° at night, and keep them syringed once or twice a day until they break into side shoots half an inch long. Then they require to be shaken out of their pots, the roots shortened, any suckers removed and placed into well drained 6-inch pots. Employ a mixture of light sandy soil composed of two parts loam, or the top spit of a pasture, to one of well-decayed manure, one part half-decayed leaf soil, and sufficient coarse sand to make the whole porous. They would then make rapid growth, and when the side shoots are a few inches long take out the points and peg out the shoots like *Verbenas* are treated; but this must be done very carefully or the shoots are liable to break off. At the end of March transfer them to a cold frame, paying particular attention to watering, and admitting air at all favourable times.

At the end of April they will require to be shifted into 8-inch pots, keeping the frame rather close for a few days, when air should again be admitted freely yet gradually, hardening them sufficiently to be placed out of doors by the end of May or the beginning of June. The plants should have the points stopped, so that they will form many shoots; but never pinch and pot at the same time, or they will break weakly. They would also require a few sticks to secure the plants against damage by winds.

About the first week in June they need the final shift into 10 or 11-inch pots, the drainage being carefully placed with small crocks to the depth of 1½ inch, and over this a layer of half-decayed turf, grass side downwards, which prevents the soil getting down amongst the crocks, and over this give a sprinkling of soot. The compost for this potting, also the shifting into the 8-inch pots before named, would be composed of two parts and a half good loam, one part decayed manure, and little half-decayed leaf soil and coarse sand. To this I would add a 6-inch potful of Clay's fertiliser, and the same quantity of soot to each barrow of the soil, the whole to be well mixed. Pot the plants very firmly, ramming the soil with a blunt stick as the work proceeds, leaving about 1½ inch from the rims for a future top-dressing. Place the plants on a thick bed of cinder ashes in some good open position, yet sufficiently screened from high winds during the season of growth. The final pinching should not be later than the last week in June; and if they have been regularly pinched they would now be forming from sixty to eighty shoots on each plant, each to

have one good flower. The watering will require regular attention, and weak liquid manure may be given all through August two or three times a week. Sheep droppings tied in an old sack and soaked in a tub of soft water form a good liquid. The plants are also benefited by syringing with very weak soot water made in the same way as the above every evening if very hot weather should intervene. Let the shoots run in a trailing manner amongst the sticks, and keep them tied in places, so as to protect them against any sudden gales.

At the beginning of September the crown buds appear—i.e., a bud would show with about three growths nestling round it. If this bud is plump and not damaged, or in any other way deformed, the growths round it can be removed, leaving the bud only for a future bloom on each. A similar bud to the one described appears earlier in the season; that is called a July bud, but that is useless, and better be promptly removed and let all the growths remain. As soon as the bud is fairly set top-dress the soil with half-decayed sheep droppings two parts, with one part loam, and a sprinkling of Clay's fertiliser, pressed firmly so as to leave sufficient space to hold the water when using it. From the 1st to the 10th of October the plants requiring housing, the most suitable place would be a good airy greenhouse, Peach house, or vinery, giving them all the air possible for a few days, and never apply fire heat unless to expel damp or frost. The plants would require a sprinkling of Clay's or Standen's manures about the middle of October, but soon as the flowers begin to show colour use nothing but clear soft water. By the end of October they would require their training; neat sticks about 2 feet long and evenly placed, the outer ones pitching onwards so as to form heads 3 feet or more through, according to the size of the plants, bringing each shoot round, so that the blooms may come to the right height. Should mildew appear well dust with flowers of sulphur; and while the blooms are expanding keep a free circulation of air amongst them upon all favourable occasions.

From the foregoing I would sum up the chief points in this way. Keep the plants growing as fast as possible, stopping the shoots at every third or fourth leaf, never allowing them to suffer for want of water; in fact, carrying out the full details herein described, and good results may be anticipated.

The following varieties I have found good for this mode of training:—Mrs. Rundle, Geo. Glenny, Mrs. Dixon, White and Pink Venus, Lord Derby, Princess Teck, Hero Stoke Newington, Lady Hardinge, Mrs. Shipman, Prince of Wales, and Mrs. Haliburton.—W. A. WALTER, *Lillingstone House*.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Colonel R. Trevor Clarke in the chair, the following candidates were unanimously elected Fellows—viz, Sir Philip Currie, K.C.B., H. R. Darlington, George Hansen, Mrs. R. L. Hatton, Henry Kruse Frank Miles, Miss D. Wemyss.

— THE attention of the Council of the Royal Horticultural Society having been called to the fact that in the Report of the Orchid Conference the name of MESSRS. W. THOMSON & SON of Clovenfords, N.B., as exhibitors of cut specimens of Orchids has inadvertently been omitted, the Council express their regret at this omission.

— EVERY year the display of AMARYLLISES AT CHELSEA appears to increase in magnitude, diversity, and richness. Messrs. Veitch and Sons have for years past devoted special attention to this gorgeous race of plants, and their annual exhibitions of them show the wonderful progress that has been made in the improvement of the flowers. The central bed in a spacious span-roofed house is now occupied with plants plunged closely together that are throwing up some 1500 flower stems. Many flowers are open, including some beautiful new varieties, and others are daily expanding. The Exhibition may be said to have fairly commenced, and for the next fortnight will form one of the most brilliant floral spectacles of the year. Visitors to the nursery will also enjoy a glance at the cool Orchids, of which hundreds are now flowering in charming contrast with the more massive and gorgeous Amaryllids. A series of exhibitions will be arranged by Messrs. Veitch during the season, and their nurseries are open free to visitors during the whole of each week day.

— ON Friday, the 26th inst., Mr. B. S. Williams will open an EXHIBITION OF SPRING FLOWERS AND ORCHIDS IN THE VICTORIA AND PARADISE NURSERY, UPPER HOLLOWAY, and a very beautiful display will be provided. There are over 200 well-grown Hyacinths of the best varieties, with Tulips, Narcissi, Lilies of the Valley, and similar forced plants. The superb plants of *Imantophyllums* will be employed in

groping with the other plants, and Orchids will include some fine Cattleyas, of which large numbers are advancing, Odontoglossums, and many valuable varieties.

— WE have been favoured with an advance copy of the first portion of the Earl of Onslow's work, "LANDLORDS AND ALLOTMENTS," published by Messrs. Longmans, Green & Co. We can only say now that it is a timely and useful publication, eminently worthy of perusal by all who are interested in the question on which it treats. The diligence of the author is very apparent, and he merits the success he has undoubtedly achieved in collecting a great amount of valuable information on an important subject that is now receiving a large share of public attention.

— WE have received a copy of the report and balance sheet of the HULL CHRYSANTHEMUM SOCIETY, which we are glad to observe is in a flourishing state. Nearly 7000 visitors attended the show last year, and £112 10s. was awarded in prizes. The balance at the bankers has been raised from £77 13s. 6d. last year to £173 1s. 9d. at the present time—an increase that justifies the policy that was pursued, and also the re-election of George Bohn, Esq., Chairman, with Messrs. Charles Judge and W. W. Cogan as Honorary Treasurers and R. Falconer Jameson and W. Hawksworth as Secretaries of the Society, which is recorded. The next show will be held on November 18th, and schedules are in preparation.

— MR. W. DANIELS, The Gardens, Hall Cross, Mirfield, sends us a flower of EUCHARIS GRANDIFLORA WITH TEN PETALS, and remarks:—"We grow a good many Eucharises, but never had a flower like the one enclosed. The bulb is planted out amongst others; the spike has seven other flowers to open." Eucharis flowers occasionally come with a greater number of petals than usual, and the instances have been rather numerous this season. Many cultivated plants vary in this way, approaching the condition of double flowers.

— A CHRYSANTHEMUM SOCIETY has been formed at Wells, Somerset, and the first exhibition will be held in the Town Hall on November 24th, 1886. For a first attempt the prizes are fairly liberal, and there is every prospect of the Society being well supported in the neighbourhood. Mr. A. G. Andrews is the Honorary Secretary, and several practical gardeners are on the Committee.

— ANY person in quest of a lovely hardy conservatory or greenhouse climber can readily find one in CLEMATIS INDIVISA LOBATA, which is so easy of cultivation. At the present time there is in the glass corridor of the Birmingham Botanical Gardens a fine plant loaded with its beautiful white star-shaped blossoms, with plenty of buds to open, and it is not only so valuable as a climbing decorative plant, but the flowers are so lovely and valuable for working up into sprays for ladies' shoulder-knots as well as for wreaths and crosses, and much can be done by the use of branches of flowers in decorations.

— THE 103rd exhibition of the products of horticulture of the ROYAL FLORAL SOCIETY OF BRUSSELS will be held in that city on April 25th, 26th, and 27th of the present year. The schedule comprises 134 classes, and about forty gold medals are provided, with a great number of silver-gilt and silver medals to be competed for on the occasion. M. Lubbers, 26, Rue de Berger, is the Secretary of the Society.

— "J. W.," Cookbridge Tower Gardens, Leeds, writes:—"On page 218 in Journal for last week I notice remarks on a CURIOUS CINERARIA. Enclosed you will find several similar blooms. All the blooms on the plant are alike, and I only have this one out of 150 plants. I cannot give any reason why the one should be distinct from the rest." An Uxbridge correspondent also sends examples of a similar freak.

— THE NEWCASTLE-UPON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY will hold their Show this year on the following dates—Wednesday and Thursday, April 7th and 8th, and Wednesday, Thursday, and Friday, July 21st, 22nd, and 23rd. Numerous classes are provided at each Show, and the prizes will be of the usual liberal character. The Secretary is Mr. T. J. Gillespie.

— GARDENING APPOINTMENT.—Mr. George Cook, foreman Eridge Castle Gardens, has been appointed gardener to Mrs. Wilson, Rauceby Hall, Sleaford, Lincolnshire.

— MR. BARDNEY writes:—"Since the winter has passed away we have had warm weather and bright sunshine in the Liverpool district, with occasional showers. Sunday was almost like summer, and Narcissus and

the buds of fruit and other trees could almost be seen growing under its influence. Crocuses have sprung into flower all at once, for on Saturday only odd ones were visible, but the following afternoon they were a glorious show. If the present weather continues, in two or three days our light soil will be in workable condition, planting and seed-sowing will be pushed forward as rapidly as possible."

— IN the years 1837, 1838, and 1839 a very interesting work, "The Floral Cabinet," emanated from the Botanical Gardens, Birmingham, edited by Mr. G. B. Knowles, then Professor of Botany in the Birmingham Royal School of Medicine, and in the volume for 1837 is a coloured plate of BEGONIA OCTOPETALA, which is described as a perennial. Root tuberous. Leaves large, kidney shaped, measuring 12 inches across and 6 inches in depth. Petals four (in the male flowers occasionally five), some of the flowers being 3 inches in diameter, and first cultivated in the Paris Garden from seeds sent from South America about the year 1778, by Mr. Joseph Dombey, the celebrated botanist and traveller. A plant is in the collection at the Birmingham Botanical Gardens, and Mr. Latham has not yet flowered it, although he has had it for four years, but he intends blooming it if possible this summer. It is, however, very rare now, but the size of the flowers is somewhat remarkable in a Tuberous Begonia of fifty years since.

— A LEEDS correspondent sends us some flower-heads of a remarkably fine WHITE CINERARIA, one of the best varieties that we have seen. The florets are broad, of great substance, and rounded in form, the outline of the bloom being sufficiently good to satisfy a florist, while the contrast of the bright purple centre is very striking. Our correspondent states that he has fifty florets from offsets, which he finds very useful for decoration, one plant in a 6-inch pot having eighty blooms. In some of the best strains it is strange that, though so many rich and bright colours are represented, white is scarce, or of a dull dirty hue.

— THE usual monthly meeting of the ROYAL METEOROLOGICAL SOCIETY was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, Mr. W. Ellis, F.R.A.S., President, in the chair. Mr. W. E. Addison, Mr. A. W. Claydon, M.A., F.G.S., Mr. T. B. Moody, R.N., and Dr. W. Schlich were balloted for and duly elected Fellows of the Society. The President gave an historical sketch of the barometer. After remarking on the accidental nature of the discovery of the instrument in the year 1643, in its best form, in ignorance for some time of its value for purposes of meteorological inquiry, he gave a brief account of many early kinds of barometers, the first endeavour being in consequence of difficulties experienced with the ordinary mercurial form to enlarge the scale of variation, attempts which, in general, introduced other errors and inconveniences. The desire to experiment on elevated positions induced the construction of an early form of portable barometer, one such with cistern completely closed leaving the air to communicate through the pores of the wood having been made above 200 years ago. The President further described various points in the arrangement of the Ramsden, Gay Lussac, and other barometers, including also mention of some modern patterns of long range barometers, standard barometers, and such barometers as are more commonly used. The practice of driving out air from the mercury by heating or boiling appears to have been in use early in the last century. Engraved plates indicating the weather to be expected with different heights of the mercury have been longer used, at least as early as 1688. As regards correction for temperature, De Luc in the last century adopted a temperature corresponding to 54.5° Fahr. as that to which to make reduction, because corresponding nearly to the average of observations, such reduction being now made to the natural zero, 32° F. Reference was made to the employment of water (as in the well-known Royal Society barometer) and other liquids instead of mercury; also to various kinds of floating and other barometers not at all or not entirely mercurial, and to metallic barometers. The President concluded his account with a sketch of the history of recording barometers or barographs, including a notice of the application of photography and electricity to recording purposes. At the conclusion of the President's address the meeting was adjourned to afford the Fellows and their friends an opportunity of inspecting the valuable and interesting exhibition of barometers.

#### ODONTOGLOSSUMS AND CATTLEYAS.

THIS year we have kept our Odontoglossum house several degrees warmer than we have ever done before, and the roots of the plants are in capital condition, better than has been the case in previous years. Our thermometer is in the centre of the house, and we have been in the habit

of preventing the temperature falling below 45°. Under these conditions the plants did well, especially at the warmest end of the house, which would be kept about 50°, but they did not succeed so well at the coolest end, which must have fallen to 40°. Last year I was induced to try the cool treatment for these plants, and in consequence lowered the temperature 5°—that is, to 40° during severe weather; but when mild it stood 45° or more, no fire heat being needed to maintain this temperature. This gave the low temperature system a fair trial, and in our case the plants went further back in three months than they made progress in one year. *O. cirrhosum* was the first to resent this treatment, and *Ada aurantiaca*; in fact plants of the latter were lost, while it is doubtful if those of the former can be thoroughly recruited in two years. We had previously grown these in the house during the winter, in which we now grow *Cattleyas*, and wonderfully well they had done. They had developed pseudo-bulbs of a large size, and the increased size of the plants had been wonderful. *O. triumphans* suffered least, and then *O. Pescatorei*. *O. Alexandræ* suffered considerably, and the plants are not so good as they were before being subjected to the cool treatment. During the past year they have made wonderful progress, and they never were in better condition at their roots.

This winter we arranged three thermometers in the house, one at each end and one in the middle, and have found that there is 8° difference between the warmest and coldest end. The one at the coolest end has not been allowed to fall below 45°, the one at the warmest end has stood at 53°. This has been during cold nights, or when the thermometer outside has been 35° and below. On mild occasions, when the temperature given could have been maintained without the use of fire heat, this was not attempted, but the pipes were kept gently warm whatever the temperature of the house might be. The plants by this treatment have done well, and in future the low temperature system will not be practised. My advice to all cultivators anxious to increase the size of their plants and the number of their pseudo-bulbs, is not to have the plants in a lower temperature than 45° to 55°, the first at the coolest end of the house during severe weather. To do *Ada aurantiaca* and *O. cirrhosum* well they should not be in a lower temperature at any time than 55° at night.

I have recently seen some *Cattleyas* that have been grown on the cool system that has found favour in several quarters during the past few years. Some of these plants have passed into the garden of a friend, and what is their condition by the side of his plants that have had warm treatment? These have been grown in a general plant stove, and have fine stout pseudo-bulbs with large bold foliage; they are in the best condition, and very healthy. The plants grown in a cool house have a yellow sickly cast, as if they have been starved, as no doubt they have. My friend has many fine pieces of *Cattleyas*, and intends erecting a house in which to cultivate them by themselves, and therefore is buying a few to assist in filling the structure when ready for them, and he says "They shall not have a lower temperature than 60°, and that during cold weather." "Will you give them much air?" was the next question; and the answer was "No, they will be ventilated on the same principle as my stove; this structure has had no air admitted through the ventilators since October last, and will get none for some weeks to come." This exactly coincides with my own experience of *Cattleyas*, for I grow them moderately warm, never having subjected the plants to a lower temperature than 60° to 65°, the former being the temperature given for cold weather, except perhaps on a solitary occasion when a night has proved very windy and cold and the temperature has been lowered rather than overheat the pipes. The whole of my plants were imported pieces obtained during the past three years, for I had but two or three plants previous to this time. They produced sheaths the first year, but they were not allowed to bloom; the second season they made good growth and flowered freely. This season again they are flowering well, and others have plenty of sheaths. The pseudo-bulbs of those imported three years ago are decidedly better, being larger and with bolder foliage than they possessed in their native homes.

I am of opinion that unless *Cattleyas* make finer growth under artificial treatment than in their native habitat they are not receiving the treatment they desire. It is unnatural for them to have a yellow sickly appearance, and this will not be the case if the plants are carefully watered during the winter and given the heat advised above. Carelessness in watering is the ruin of more *Cattleyas* than any other cause. If over-watered during the winter or their resting period they will fail to do satisfactorily.—S. W. D.

#### ACANTHEPHIPIUM BICOLOR.

AMONGST the floral treasures found by Blume was an Orchid discovered in the woods of Mount Salak, Java, and which proved to be so distinct from any then known, that a genus was founded upon it, and the plant was named *Acanthephippium javanicum*. The characters upon which that botanist relied were sufficiently important to deserve generic rank, and though there have been many alterations in the nomenclature of Orchids, this has been retained and was adopted by the late Mr. G. Bentham in his review of the family. Botanically the genus is nearly related to *Bletia*, and with that the author last named placed it in the sub-tribe of the *Epidendreae*, *Bletieae*. In appearance, however, the few species known are but little like the *Bletias*, the pseudo-bulbs being stout, conical, covered with the sheathy bases of leaves, and bearing at the summit

broad lanceolate leaves with strongly marked ribs. The young shoots rise from the base of the old pseudo-bulbs, and with them are produced the few-flowered racemes of somewhat tubular flowers, the sepals and petals closely surrounding the lip and column. The colours are curious—not so bright as many Orchids now in cultivation, but they are attractive, and a well-grown plant like that shown in the woodcut is worth a place in a collection.

*A. javanicum*, already noted, was the first known, but does not seem to have been introduced until 1844 or a little before that time, as in that year a plant flowered in Loddiges' nursery, and was figured in the "Botanical Register," t. 47, 1846. It subsequently flowered at Kew, and was figured in the "Botanical Magazine" in 1850. The varieties represented in these two plates differ in colouring considerably; the earlier one has yellowish flowers striped with purple outside the inner surface and the lips of sepals and petals being of a purplish lilac colour; in the other the yellow is much brighter, and the streaks are reddish, with a tinge of purple. The species is readily distinguished by the lip being deeply three-lobed, the centre lobe contracted in the centre, and toothed.

*A. bicolor*, of which a plant is represented in fig. 44, though not discovered until some time after *A. javanicum*, was first introduced to this country, as it was figured in the "Botanical Register" in 1835, t. 1730. It was found in Ceylon by Mr. Watson, then superintendent of the Government Garden at Peradenia, and by him was sent to the London Horticultural Society. The flowers are yellow, the petals streaked with red on the inner surface, and the sepals deeply tipped with a darker shade of the same colour. The engraving was prepared from a plant shown by Sir Trevor Lawrence, Bart., M.P., at the Orchid Conference in May last year.

*A. striatum* is another species that has been described by Lindley and Mr. Bateman as possessing "French white" flowers, and another has been described under the name of *A. sylhetense* with "white scentless flowers," but these are little known, and if they are in cultivation they are confined to collections of rarities. *A. bicolor* succeeds well in a pot with peat and light turfy loam in an intermediate or *Cattleya* house, giving plenty of water during growth, and having a well-marked season of rest.—L. C.

#### HORTICULTURAL SHOWS.

##### LIVERPOOL.

THE fourth Spring Show of this Society was held in St. George's Hall, on Thursday, March 18th. The Exhibition on the whole was not quite equal to those of previous years. The weather was most unfavourable, and deterred many competitors from staging their plants. The number of entries were never so numerous, and it was anticipated that the Exhibition would prove a remarkable one.

*Stove and Greenhouse Plants.*—The large *Crotons* and *Palms* that usually adorn the Exhibition from Wyncote Gardens were missed this year, but there were some remarkably fine plants. In the class for six plants, three flowering and three foliage, three competitors staged. Mr. A. Crosbie, gardener to B. Hall, Esq., was first with a grand plant of *Croton angustifolius* about 5 feet through and well coloured; *Lantana borbonica*, and a good *Croton Mooreanus*; a large plant of *Rhododendron Gibsoni* being noticeable. Mr. J. Jellico, gardener to F. H. Gossage, Esq., Camp Hill, Woolton, was a close second; and Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, was third, and staged *Cattleya intermedia* with about sixteen flowers. For one greenhouse plant Mr. G. Rhodes, gardener to Mrs. Horsfall, Aigburth, was placed first with a large well-flowered example of *Imantophyllum miniatum*. Mr. J. Lowndes, gardener to S. S. Parker, Esq., second with *Chorozema cordatum* splendens well grown and flowered. Mr. C. Copple, gardener to T. S. Rogerson, Esq., St. Michael's Hamlet, third, with a similar plant to the first named, but not quite so well flowered. For one stove plant Mr. A. R. Cox took the lead with *Phajus grandifolius* with five or six large spikes. Mr. A. Crosbie followed with the same variety. Mr. H. Went, Mere House, Newton-le-Willows, secured the remaining prize with a *Gardenia*. The best single foliage plant was from Mr. A. Crosbie, a large specimen of *Asparagus plumosus*; Mr. A. R. Cox, being second with *Dracena Baptisti*.

*Groups.*—In the class for a group of miscellaneous plants arranged for effect to occupy a space of 50 square feet in semicircular form, two competitors entered, and the groups were better than they have been before at the spring shows. Mr. A. R. Cox was first with a tasteful arrangement, the groundwork being formed with *Ferns*, *Orchids*, *Azaleas*, *Cinerarias*, *Primulas*, and *Narcissus*, with highly coloured *Crotons*, *Dracenas*, *Aralias*, and *Palms* rising above them, edged with *Panicum variegatum* and dwarf red *Tulips*. Mr. J. Jellico, Camp Hill Gardens, secured second honours with a very pretty but not such a light arrangement.

*Azaleas.*—These were fairly well represented, and the premier plants in the open class were well grown specimens. Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorsey Cop, Gateacre, was the most successful with *Criterion*, *Charmers*, *Striatum*, *Flag of Truce*, and *phoenicea*. Mr. A. Crosbie was second, but these plants were not fully out. In the amateurs' class for four plants in 8-inch pots Mr. P. Barber was placed first with healthy well-flowered plants. Mr. T. Gowan was second with rather smaller plants, and Mr. A. Crosbie third. With one plant Mr. J. Lowndes was first with a very large profusely flowered plant of *Virgin Queen*. Mr. J. Jellico was second, having also a fine plant of *Fielder's White*.

The Rhododendrons staged were large and well bloomed. Mr. W. Bustard was awarded the first prize for large plants of Vesuvius, The Queen, Victoria, and Mrs. Bradshaw. For one, Messrs. W. Bustard and J. Lowndes were the winners in the order named. For one greenhouse variety Mr. G. Rhodes was first with a grand specimen of R. Gibsoni.

**Miscellaneous Plants.**—With six forced plants Mr. W. Bustard was well ahead, showing *Deutzia gracilis* 3 feet through, *Azalea mollis* very fine, *Maréchal Niel* Rose, and a nearly white Ghent *Azalea*. Roses were only fair. For four plants Mr. A. R. Cox was first with *Niphetos*, *Homère*, *Souvenir d'Elise*, and *Reine Marie Henriette*. Mr. J. Jellico was second, his best plants being *Général Jacqueminot* and *Isabella Sprunt*. For one plant Mr. J. Agnew was first with a large well-bloomed plant of *Comtesse de Sembie*. *Primulas* were not so good as are generally exhibited. *Cinerarias* were better than they have generally been. *Lily of the Valley* was remarkably well shown, and the competition for the three prizes offered for six plants in pots was very keen. *Cyclamens* were not largely shown, but those staged in the class for six plants were remarkably good. Table plants were staged in the usual style, the plants being small, neat, and light. Ferns were in splendid condition although not numerous. Mr. T. Gowan's plants being extremely fine. Palms and Cycads were not quite so largely shown as usual, but Mr. Crosbie had some fine specimens.

**Hyacinths in Pots.**—These were not quite up to the same standard as in previous years, although some fine well-developed spikes were shown. Four collections of eighteen distinct varieties were staged. Mr. C. Wearing, gardener to Mrs. Aikin, Princess Park, was well to the front with well grown plants, some of the best being *Von Schiller*, *King of the Blues*, *Gigantea*, *Grandeur à Merveille*, *Czar Peter*, *Vuurbaak*, very fine; *Mont Blanc*, *Lord Derby*, *Baron Van Tuyll*, *Fabiola*, *Baroness Van Tuyll*, *Koh-i-noor*, *Alba Maxima*, *Marie*, *Blondin*, and *Grand Maître*. Mr. J. Kelly, gardener to R. Singlehurst, Esq., Aigburth, second, this collection having very good spikes, but the foliage was slightly drawn. Mr. E. Green, The Hollies, Mossley Hill, third. For twelve distinct varieties, Mr. J. V. Thompson, gardener to W. P. Sinclair, Esq., Princess Park, was first, and staged good examples of *King of the Blues*, *Princess Clotilda*, *Grand Maître*, *Blondin*, *Ida*, very fine; *La Franchise*, *Lord Derby*, *Koh-i-noor*, *La Grandesse*, *Grand Lilas*, *Macaulay*, and *Alba Maxima*. Mr. J. Bounds, gardener to A. S. Jones, Esq., Oaklands, Aigburth, second; and W. Kneale, gardener to Captain Gaskell, High Cliffe Lodge, third; four collections being staged. For six plants the fortunate competitors were Messrs. J. V. Thompson, C. Copple, and C. Wearing. In the corresponding class for six pots, three bulbs in each pot, some grand examples of culture were staged. Mr. J. Jellico took the lead with some very fine spikes of *Marie*, *Baroness Van Tuyll*, *Grand Lilas*, *Robert Steiger*, and *Baron Van Tuyll*; Mr. T. Stephenson, gardener to R. Cornelius, Esq., Waterloo, second; and Mr. Peter Barber, third.

**Tulips.**—Mr. Kneale took the foremost position in the class for two pots of single varieties, not less than six distinct varieties. This collection comprised good examples of *Proserpine*, *Keyzers Kroon*, *Alba Regalis*, *Couleur Cardinal*, and *Joost van Vondel*. Mr. A. Collins was placed second, having very fine *Fabiola*, *Chrysolora*, *Joost van Vondel*; Mr. J. Kelly being third with fully expanded examples. For six pots of single varieties Mr. C. Wearing was placed first, and staged *Vermilion Brilliant*, *White Pottebakker*, *Joost van Vondel*, *Wouverman*, *Standard Royal*, and *Chrysolora*. Second Mr. J. Lowndes, and third Mr. C. Copple. For six pots of doubles Mr. E. Green was first, Mr. Copple second, and Mr. J. Lowndes third.

*Narcissus* were good, and the prizes offered were well contested; for six pots, not less than three varieties, Mr. J. V. Thompson was first, having *Apollo*, *Sir Walter Scott*, and *La Parfaite* good. Mr. C. Wearing was second and Mr. J. Jellico third, eight or nine collections being staged.

The lateness of the season enabled *Crocuses* to be staged in fine condition. The competition in the class provided for six pots was remarkably good. The prizewinners were Messrs. J. V. Thomson, J. Bounds, and P. Barber, in the order named.

**Orchids.**—These were not staged in large numbers, but the exhibits throughout were of good quality. In the class for four plants Mr. T. Worth, gardener to E. Harvey, Esq., Riversdale, Aigburth, was first, followed by Mr. E. Green, Mr. W. Moss, gardener to W. Holland, Esq., Mossley Hill, and Mr. A. Smith, gardener to D. de Yborrondo, Esq., Sefton Park; the two last being equal thirds. The premier collection contained *Cattleya Trianae* *Osmani*, with five highly coloured flowers. A basket of *Dendrobium crassinode*, *Cymbidium Lowianum* with two fine spikes, and a remarkably fine variety of *Dendrobium Falconeri giganteum* with thirteen highly coloured flowers nearly 3 inches in diameter. The second collection contained a good *Vanda tricolor* and *Cattleya Trianae*. For one plant Mr. T. Worth again took the lead with *Dendrobium crassinode album*, a remarkably fine variety. The plant had one very strong pseudo-bulb well flowered, the colour being of the purest white, and the flowers large, being equal to those of good varieties of *D. Wardianum*. Mr. G. Rhodes was second with a large pan of *Cœlogyne cristata*.

**Bouquets and Cut Flowers** on the whole were very good, the flowers being choice and tastefully arranged, and their size moderate. Mr. A. Crosbie took the lead in the open class with an arrangement of *Eucharis*, *Dendrobiums*, *Lily of the Valley*, *Spiræa*, *White Lilac*, and *Erica melanthera* towards the outer edge. The principal colour was provided by *Dendrobium nobile* and *Euphorbia jacquiniæflora*. Messrs. S. Martin & Co., florists, Hope Street, Liverpool, were the second. Mr. G. Down's, Lodge Lane, obtained the remaining prize. In the corresponding class for amateurs the same exhibitor was again first with a very similar bouquet to the one staged in the previous class; the ground being nearly all white with a few flowers of *Sophronitis grandiflora* and scarlet *Bonvardia*.

Cut flowers were bright, the prizes being taken by Messrs. A. R. Cox, A. Collins, gardener to S. Smith, Esq., M.P., Princess Park; G. Rhodes; Mr. G. Park, gardener to R. A. Farrington, Esq., Wigan.

**GRAPES.**—Though not shown in large numbers the competition for the prizes offered for two bunches was good, as seven or eight exhibitors staged. The examples throughout were most creditable considering the season. Mr. W. Hannagan, gardener to R. N. Naylor, Esq., Hooton Hall, was placed first with *Alicante* Mr. T. Elsworth, gardener to R. A. Gladstone, Esq., Court Hey, second with larger bunches and plumper fruit, and Mr. G. Middleton third with *Muscat of Alexandria*. The last exhibit deserves

special notice, for the examples staged were of perfect colour and had been kept remarkably well.

**MISCELLANEOUS EXHIBITS.**—These were perhaps more numerous than usual, and contributed in a large degree to the beauty of the Exhibition. Messrs. J. Dickson & Sons, Chester, had a collection of border *Narcissus*, Alpine, and herbaceous plants in flower, for which a first-class certificate was awarded. Messrs. R. P. Ker & Sons received the same award for a splendid bank of *Azaleas* in 5 and 6 inch pots. Messrs. Cutbush & Sons, Highgate, London, contributed a large bank of *Cyclamen* very fine, *Azaleas*, *Oranges* in small pots, Palms, and a collection of *Hyacinths*. Amongst the last were the finest spikes in the Exhibition, the bells being larger than was the case in other exhibits. Most of the well-known varieties were good, but pink *Baroness Van Tuyll* deserves special note. Messrs. Fisher, Son, & Sibray, Handsworth Nurseries, Sheffield, staged boxes of cut blooms of greenhouse *Rhododendrons* and a number of fine plants in pots covered with bloom. The plants in pots were 3 feet through them, well furnished and flowered. Mr. W. Nicholson, gardener to A. M. Smith, Esq., Raby, staged a case of skeleton leaves that was highly commended. A first-class certificate was awarded to T. Davies & Co. for a collection of *Hyacinths*, *Tulips*, and *Lily of the Valley*. The Horticultural Company (John Cowan), Garston, also contributed largely to the Exhibition by having some hundreds of *Hyacinths*, *Tulips*, *Narcissus*, *Azaleas*, *Spiræas*, Ferns, and Orchids. Amongst the last *Cattleya Percivaliana* and *Odontoglossum Andersoni* were conspicuous.

The arrangement of this fine Exhibition was all that could be desired, and everything was carried out in a satisfactory manner; great credit being due to the Committee of Management and the able Secretary, Mr. E. Bridge.

#### PRESTON AND FULWOOD SHOW.

THIS Society held its eighth annual spring Show in the new Public Hall, Preston, on the 17th and 18th inst. The schedule comprised eighty-three classes divided into four divisions—namely, five open for nurserymen and florists, sixty-four for gentlemen's gardeners and amateurs, one for amateurs not possessing more than 500 feet of glass, and thirteen for cottagers' productions. Some idea of the extent of the Exhibition may be gained when it is stated that the whole of these classes were represented with the exception of two. The plants are all staged on the evening previous to the Exhibition, so that the Judges can commence their duties the following morning, which gives ample time without being hurried in. But the Committee would do well to have the cut flowers arranged on the morning of the Show instead of the previous evening.

*Hyacinths* were the leading feature of the Exhibition, and were well grown, the spikes being evenly developed. In the open class for twenty-four single varieties, distinct, Mr. E. Payne, nurseryman, Fulwood, was well ahead of Mr. H. Winwood, Ashton, the other only competitor, who was awarded the second prize. In the corresponding class for the same number of double varieties the same two exhibitors staged plants and obtained the awards in the order named. In the amateurs' class for twenty-four single varieties, distinct, J. B. Dixon, Esq., Treasurer of the Society, was the only exhibitor, and was deservedly awarded the first prize for a well-grown collection. For twenty-four double varieties the same exhibitor again took the lead with capital examples. In other classes the prizetakers were Mr. J. B. Dixon and Mr. R. Learell, gardener to R. Smith, Esq.

Six classes were devoted to Tulips, and most of those that took the leading places were in splendid condition. The prizetakers were Mr. J. B. Dixon and Mr. T. Moss, who had well-grown specimens. *Narcissus* were staged in grand condition, both *Polyanthus* and border varieties. Five classes were devoted to them, and Mr. J. B. Dixon took the lead in all.

For twenty pots of bulbs, corms, tubers, or rhizomes in flower in 6-inch pots three collections were staged. Mr. T. Moss secured the premier position, followed by Mr. J. B. Dixon. The first collection was good, and some of the plants very effective; it comprised fine examples of *Allium neapolitanum*, *Eucharis amazonica*, *Cyclamen* red and white, *Narcissus Horsfieldi*, *Lilium longiflorum*, and *Lachenalia*.

*Primulas* were exhibited in fine condition. For six plants of any variety Mr. A. Waters, gardener to J. Eccles, Esq., Farington House, was well to the front with the most profusely flowered plants we have seen for some years. *Cyclamens* were not largely represented, only five collections being staged for the six prizes offered in the two classes, Messrs. Whittle and T. Moss being the prizewinners. *Lily of the Valley*, *Deutzias*, table plants, and others were also well shown by the exhibitors already named.

In the class for a miscellaneous collection of plants arranged for effect, not to exceed 100 square feet or 10 feet of frontage, three competitors entered. Mr. T. Moss was first with the brightest and most effective arrangement. This collection contained a large number of flowering plants. Mr. J. B. Dixon was second, but many of the plants were not very choice. Mr. Frisby was third, a large number of Ferns being employed. The back of this group was very effective with *Lomaria gibba* and *Blechnum corcovadense*, with *Nicotiana affinis* peeping out. If this group had had two or three brighter plants towards the front, rising lightly from the Mosses and Ferns, which was rather flat, it would have been the best.

For three foliage plants Mr. J. B. Dixon took the lead with a good plant of *Cycas revoluta*, *Phoenix rupicola*, and *Pritchardia filamentosa*; Mr. F. Clark being second with *Pandanus utilis*, *Cycas revoluta*, and *Latania borbonica*; and third Mr. Frisby. For six miscellaneous plants the prizewinners were Messrs. Frisby, J. B. Dixon, and J. Clarke, gardener to Mrs. Birchell. With six *Azaleas* Mr. J. Dixon took the lead, showing fair-sized plants profusely flowered. Mr. Wright had the best three Orchids—*Dendrobium Wardianum*, *Cypripedium Boxalli*, and *C. villosum*. For one plant the same exhibitor was again first with *Cattleya Trianae* well bloomed, some of the spikes carrying four large blooms.

Cut flowers and bouquets were not largely represented, and those shown had suffered through being staged on the previous evening. For one basket of flowers Mr. Wright, gardener to J. S. Slater, Esq., was first with a choice assortment, Mr. C. Parker being second, and Mr. T. Moss third. For one vase of flowers Mr. T. Moss was the only exhibitor, and was awarded the first prize. For one bride's bouquet Mr. Widdling, gardener to Colonel Wilson, was first.

Three prizes were offered for six varieties of vegetables, but only two collections were staged. Mr. Frisby was deservedly first, staging good

dishes of Seakale, French Beans, Mushrooms, new Potatoes rather small, a dish of small Tomatoes, and a good dish of Asparagus.

**Miscellaneous Exhibits.**—Mr. Troughton, nurseryman, 4, Church Street, Preston, and Walton-le-dale, had a very effective bank of foliage and flowering plants, Lily of the Valley, Hyacinths, Azaleas, and Dracæna Lindenii being especially noteworthy. The Society's first-class certificates were awarded to the following Azaleas:—Mons. Louis Obert, very bright double; Souvenir de Madame Vervaene, and Max-Von Froebell. This collection also contained specimens of a new Scolopendrium, named by Mr. Moore S. vulgare crispum ornatum Athertonii, after Mr. J. Atherton, who raised it. This was awarded a first-class certificate. Mr. J. Atherton was highly commended for a large group of succulent plants, which added to the interest of the Exhibition. Mr. Frisby received a similar award for a clump of Mushrooms and a splendid case of skeleton leaves. The Secretary, Mr. J. Atherton, Fern Bank, Cudley, deserves congratulation, for the success of the Exhibition in a very large measure depends upon his exertions. The whole of the staging and other arrangements entirely devolve upon him, and they were ably and successfully carried out.

#### BRISTOL.—MARCH 17TH AND 18TH.

THIS annual Exhibition was held in the Colston Hall, Bristol, and though it would not have been surprising if the very cold weather had spoilt the Show, there was no marked falling-off in the number of entries or the quality of the exhibits.

**Bulbs.**—These were not quite so well represented as usual, and the Judges were much less time in making their awards than is often the case. The principal class comprised eighteen Hyacinths, distinct varieties, and twelve pots of Tulips, and five collections were in competition. Mr. G.

gardeners to H. St. Vincent Ames, Esq., was third. Mr. Rye was also first with four plants, and Mr. F. Edwards, gardener to J. Lysaght, Esq., second. Mr. Bannister had the best six Ferns, these consisting of good-sized healthy plants of Adiantums farleyense, formosum, and trapeziforme, Microlepia hirta cristata, and two Gymnogrammas. Mr. E. Miller was a good second. Mr. Rye was first with four flowering plants, these consisting of a good white Azalea, Phajus grandifolius, Genetyllis tulipifera, and Phœnocomia prolifera. Mr. E. S. Cole, gardener to W. Pethick, Esq., was second, and Mr. Perry third. Fewer large Azaleas than usual were shown, but some of them were beautifully flowered. Mr. C. Taggett had the best four plants, and was awarded first prize and the silver medal of Royal Horticultural Society. They consisted of good pyramids of Mrs. Turner, Model, Iveryana, and Souvenir du Prince Albert. This exhibitor was also successful in the other classes, as also were Messrs. Perry and E. S. Cole. Table plants are always good at Bristol. Mr. R. Morse, gardener to S. Budgett, Esq., was first with elegant well-coloured plants of Pandanus Veitchii, Cocos Weddelliana, Croton Johannis, C. Warrenii, Dracæna nigro rubra, and D. Willsii. The best six table Ferns were shown by Mr. J. Loosemore, gardener to W. Cooper, Esq. Cinerarias were particularly well shown by Mr. F. Edwards. Cyclamens were also good, Mr. S. Blacker, gardener to Miss Charles, being first, and Mr. F. Edward second, the latter having much the best strain. Messrs. Bannister, R. Bow, and W. Webley were the prizewinners with single Primulas; J. H. Vallance, gardener to J. C. Wall, Esq., H. Sprey, and S. Pemfrey, gardener to D. Thatcher, Esq., with double Primulas; E. Miller, E. S. Cole, and F. Edwards with Violets, and H. Sprey with Mignonette, the exhibits being creditable throughout. Mr. Nicholl was first for a single Orchid, having Phalænopsis amabilis in fine condition, the same plant and spike of bloom being first last November.

Fig. 44.—ACANTHEPHIPIUM BICOLOR. (See page 233.)

Marsh, gardener to M. Dunlop, Esq., was rather easily first, having massive, well-developed spikes of Hyacinths and Tulips of the usual varieties. Mr. W. Lintern, gardener to W. Butler, Esq., was a fairly good second, his Tulips being very sturdy and fine; and Mr. F. Perry, gardener to H. Cruger Miles, Esq., was third, his collection comprising several good Hyacinths. Only Mr. R. Bow, gardener to F. W. George, Esq., competed in the class for twelve Hyacinths, and was awarded the first prize for a fairly good collection. The next class was for twelve Hyacinths in four colours, and this brought together several good exhibitors—Messrs M. Hookings, F. Perry, and C. Taggett. In a corresponding class confined to amateurs Mr. W. Lintern was first, Mr. Bow second, and Mr. C. Taggett third, each including fairly good examples of well-known sorts. Other exhibitors in smaller classes were Messrs. Marsh, Gilbert, Howes, C. Taggett, H. Spry (gardener to T. Gibson, Esq.), Hookings, and G. Shelton (gardener to W. K. Wait, Esq.). Hyacinths in glasses were particularly good, the best of them being equal to the majority shown in pots, especially those from Mr. M. Hookings. Tulips, like the Hyacinths, gave evidence of having been hurried into bloom, and were scarcely so good as usual.

**Fine-foliaged and Flowering Plants.**—There were two competitors with groups of plants arranged to occupy a space 12 feet by 7 feet, and both exhibits were remarkably good. They were formally arranged, but as only flowering plants were used this could scarcely be termed a fault. Mr. F. Perry was awarded the first prize, owing, probably, to the number of good Orchids shown in his group. The remainder of the group consisted of well-flowered Azaleas, Pimcleas, Deutzias, Cincarias, Lichenalias, and various forced bulbs. Mr. W. Rye obtained the second prize for the freest and most imposing display, which included large Camellias, Azaleas, and various other good hardwooded plants. With six fine-foliaged plants Mr. Rye easily secured the premier award, having grand specimens of Crotons pictus, Weismanni, and interruptus, Latania borbonica, Areca sapida, and Pandanus Veitchii. Mr. E. Miller was a good second, his best being fine healthy specimens of Cycas revoluta and Cibotium spectabile. Mr. W. H. Bannister,

**Cut Flowers.**—The classes for these were increased, and may be said to have been the most attractive in the Show. Four beautiful stands of twelve bunches of cut blooms, distinct varieties, were in competition, the first prize going to Mr. F. Perry, who had all Orchids; Mr. E. Miller was second and Mr. E. S. Cole third, both having good Orchids. Mr. E. S. Cole had the best twelve Roses, these consisting principally of Marshal Niel and Catherine Mermet. Mr. E. Miller had fresh blooms of Niphetos and Devonensis, and was awarded the second prize. Four competed for the prizes offered for a vase of cut flowers, and all were of nearly equal merit, the flowers being very choice. Orchids predominating. The first prize and bronze medal of the Royal Horticultural Society was awarded to Mr. A. Stapleton. Bouquets were plentifully shown, but were not so good as usual.

**Fruit and Vegetables.**—Some well-kept bunches of Grapes were shown, Mr. Nicholl, gardener to Mrs. Miller, being first with Lady Downe's in excellent condition; Mr. Loosemore was second with Muscat of Alexandria, and Mr. E. S. Cole third with Lady Downe's. Mr. J. Stapleton, gardener to H. Mardon, Esq., had the best Pears, a good dish of Catillac; Mr. E. T. Hill taking the second prize with Uvedale's St. Germain. Mr. Bannister was first with Apples, having a fine dish of Ribston Pippins; Mr. Hill following with Reinette de Canada; and Mr. J. Aplin, gardener to W. M. Baker, Esq., was third with a highly coloured dish of Northern Spy. The best basket of vegetables was brought by Mr. Bannister, these consisting of Snow's Broccoli, Welford Park Kidney Potatoes, Leeks, Brussels Sprouts, Mushrooms, Danvers's Yellow Onions, Seakale, Beet, and Carrots, or one dish too many, and had to be disqualified, an extra prize, however, being awarded. Mr. Aplin secured the first prize with a good basket, Asparagus being very fine, and Mr. J. Nicholl was a good second. The first prize for Cucumbers was awarded to Mr. J. H. Vallance for a good brace of Telegraph.

**Not for Competition.**—From J. Dorrien Smith, Esq., Trescoe Abbey, Scilly Isles, came a grand collection of cut blooms of Narcissi. Messrs. Garaway & Co, Durdham Down Nursery, Clifton, arranged a fine bank of well-grown Hyacinths and Tulips, among which were several new sorts, as

well as a good selection of the best of the older varieties, and they also contributed a useful variety of other stove and greenhouse plants, all of which added largely to the general effect.

The Secretary, Mr. Polkenhorn, and the practical Committee deserve much praise for the admirable Show provided.

### THE WEATHER AND VEGETATION.

WE have received a great number of communications respecting the weather and its effects on vegetation, and as the season has been a remarkable one the record is interesting. Happily, since the majority of these letters were written a surprising change has occurred in the weather. The temperature in the south of England has risen considerably, with mild winds and occasional showers, reminding us of April. Already this change has begun to affect vegetation, and the buds of fruit trees are rapidly advancing, while vegetables generally are beginning to freshen and renew growth. We thank our correspondents for the information they have conveyed in the following letters and others that remain to be published.

#### BERKSHIRE.

WE had many frosts up to February. We may say the weather was quite seasonable, but February itself was more severe than usual, with cold N.E. winds and frosts, very little snow or rain. March has been a continuation of severe frosts; wind, E. and N.E. Up to the present date 9° of frost is the lowest registered here this month; that was on the 1st. On the 7th we registered 19° of frost, other dates from 11° to 15°. The effect upon all vegetation is remarkable; nothing seems to have escaped the frost and cold east winds. The oldest inhabitants in this district never remember such a February and March.

One thing I have noticed most particularly—i.e., the number of white frosts we had both in February and March, and also the small quantity of snow and rain. Whilst other districts were having large quantities of snow we had scarcely any.—CHARLES HOWE, *Benham Park Gardens, Newbury.*

#### CAMBRIDGESHIRE.

OUR first frost came the first week in November, and destroyed all Dahlias, Heliotropes, and other tender bedding plants. It ranged from 3° to 7°, and lasted a week. The rest of the month was mild, but on December coming in frost and snow was the rule, 8° being the most registered. Outdoor Chrysanthemums, and other late-flowering plants, were cut off; but at Christmas time or for a day or two the weather was somewhat mild, then frost again set in, and from that time until March 16th the frost has been continuous, but more or less severe. Several times 8°, 10°, and 12° were registered, but on March 7th (Sunday) the glass stood at 15°, or 17° of frost. This has not been reached since by 3°—one occasion 14° and another 12°, but mostly ranging from 4° to 10°. Much snow has fallen at times, and has laid on the ground for weeks; but a partial thaw has occurred at times, and melted the snow sufficient to expose many things to the action of the frost, and much damage has been done to vegetables. Broccoli for spring use has all been frozen through, and the heads are rotting off. Cabbages, both old and young, are blackened and dead, as also are Winter Onions, Spinach, &c. Brussels Sprouts have stood the best, and among four sorts grown the Aigburth and one called Craig's Favourite are the least injured. Shrubs are cut about a good bit, but not, I think, permanently injured. On farm land I never saw the Wheat plant so much blackened; the same may be said of grass land. Many strange birds are visiting the neighbourhood in search of food; some are dying.—THOS. RECORD, *Brewery House Gardens, Royston.*

#### CUMBERLAND.

THE winter of 1885-86 will long be spoken of in this district as one of great severity. Sudden changes were characteristic of the weather from the middle of November, 1885, to the beginning February, 1886. During that time on several occasions we had all sorts of weather, except sunshine, in twenty-four hours, rain, snow, and frost alternated with each other for about six weeks. Since the beginning of February, however, the weather has been steady in character. North and north-east winds with heavy snowfalls and sharp frost have prevailed since February came in up to the present time, and to-day, 17th March, snow has fallen to a depth of 3 inches, and while I write, with a cold north-east wind blowing, there is every probability of a keen frost again to-night. The most severe frost that we had here in February occurred on the nights of the 1st, 2nd, 3rd, and 4th, when the thermometer indicated 22°, 23°, 21°, and 19° of frost respectively. We have had frost every night since March came in, the severest being on the nights of the 6th, 7th, 8th, and 10th, the thermometer marking 24°, 19°, 16°, and 20° of frost on the respective nights. The effects on vegetation of the weather indicated above cannot at present be defined with accuracy further than that the buds of deciduous trees and shrubs are not in a more advanced state now than they usually are in ordinary seasons the third week of February, and that, with the exception of Snowdrops, there is a total absence of spring flowers, except when they are located in sheltered cosy nooks. I expect Roses will have suffered, and several, I fear, will not recover. In the kitchen garden a clean sweep has been made of Cabbages. Brussels Sprouts have not been much injured, Broccoli are all killed, Lettuce and Winter Spinach the same. Celery has suffered where not specially protected, and autumn-sown Onions are nearly all destroyed. As a matter of course outdoor work is very much behind, and a general depression is the prevailing feeling amongst farmers and gardeners in this district.—J. HAMMOND, *Brayton Cumberland.*

#### DERBYSHIRE.

THE Derbyshire climate is always a mixture of winter and summer, but we have missed the spring this year. On the 21st of August, 1885, we had 7° of frost, which destroyed our Vegetable Marrows, Beans, and Dahlias. We experienced sharp frost again in September and October that quite destroyed Cauliflowers, Lettuce, and greatly injured our Chrysanthemums and many other plants outside, also spoilt late Plums and Cherries on walls. All kinds of berries last autumn have been abundant, and many of the old hands prophesied a hard winter, which has been the case. For the last three months we have had frosts nightly, with strong easterly cutting winds that have destroyed all kinds of green crops with few exceptions, such as a few Sutton's Late Queen Broccoli, and a variety of very hardy and delicious Welsh Kale, that we find most serviceable. This Kale would be a useful agricultural crop, withstanding any weather, and very productive, greedily eaten by sheep, &c. I find we have had frost on every night through March. On the 7th at 8 A.M. we had 22°, which I believe to be the most severe thus late in the season ever remembered. Strawberries are completely shrivelled, Apricot buds fall off, many Rhododendrons are much injured, also Hollies are shedding foliage in exposed situations, but we cannot tell yet the amount of damage.—J. H. GOODACRE, *Elvaston, Castle Gardens.*

THOUGH we had slight frosts previous to December 8th, I date our wintry weather from that time. On that and the three following days we registered consecutively 12° frost, with a thermometer 3 feet from ground in a sheltered place. The 12th and 13th of that month showed signs of thaw, having dense fogs, which we often get at this season on these hills. The ice house was filled on the 14th. Fogs continued till Christmas day, which was dry and frosty. 28th, Strong west wind blowing, so looking out for rain we set to work hard and fast, pushing on with digging, but the afternoon put a stop to all digging operations with a storm of snow and hail, settling down to rain, and we have not been able to have a square yard dug since. 29th, Registered 12° of frost with fall of snow. So ended the old year.

1st, 2nd, and 3rd January, 1886, mild; heavy rain during night of 3rd, clearing away most of snow: 6th, sharp frost set in again, heavy fall of snow on the 8th; 16° frost on the 9th; sun broke out on 11th; 12th and 13th, sleet and rain, taking away deal of snow; 17th, heavy snow; 18th and 19th, registered 19° and 20° of frost; 29th, 4 inches snow fell through the day; 31st, day of snow. February, opening with snow, bright and sunny, continued through the month frosty, increasing the last week. March, strong east wind blowing, heavy fall of snow in all directions whole of the day, with 6° frost. Shrubs weighed down with snow, but escaped here unhurt. Average fall 8 inches: 4th, registered 14° frost, heavy snow following day, continued sharp up to the 11th, since frost daily, 8° to 4°; had very heavy snowstorm from 3.30 to 4.10 on Monday 15th, snow falling whole of the day, 16th, with 7° frost.

I can form but a slight idea how vegetation has stood being so much under snow. All Broccoli killed except a flat of Sutton's Late Queen, which looks well just peeping out of snow. Curled Greens, Chou de Burghley, Chou de Russie, we can find a bit to cut at, but poor. Good stock of Lettuce and Parsley under the snow. I find a good lot of Christmas Roses yet for gathering under handlights, also Winter Aconite under the snow. Wallflowers all killed; large clumps of Heuchera look withered. All shrubs seem to have escaped, large Coronilla glauca, that has stood several years, was broken with snow; another plant looks scorched, but is not dead. Euonymus, Escallonia, &c., against wall have the foliage slightly injured. A large plant of Rêve d'Or Rose against a wall seems killed, but with the quantity of snow still lying can give no correct statement.—GEO. BOLAS, *Hopton Hall Gardens.*

#### DORSETSHIRE.

FOR warm Dorset, as it is often called, we have experienced a most severe winter and its effects on vegetation. Since last October we have registered frost almost every night; the most was 18° on the 27th February, and again on the 16th March. The green crops are scarce. Broccoli we have lost in hundreds. Snow's and Penzance varieties, which in other seasons we used to cut in abundance, were all killed by frost in January. We have to look forward to the late varieties; the two sorts which seem to have weathered the storm best are Veitch's Model and Sutton's Late Queen. Cabbage plants, which were put out in their quarters about the first or second week in September, are as forward as when put out, as very little growth has been since the middle of September. There has been but very little snow. We only had the ground covered once—the 5th of March, which lasted a few days. A cold dry March gives us a better chance of a warm moist May.—D. WILLIAMS, *Gardens, Canford Manor, Wimborne.*

THE present winter has been the longest we have ever experienced here, and second only in severity to that of 1854-5, whilst its effects on vegetation are without parallel in my recollection. We had very severe weather early in September, when a succession of frosts proved fatal to French Beans and Marrows, and checked the growth of all root crops to such an extent that they have never fairly recovered. The loss to local raisers of Cabbage plants was very heavy. A continuation of hard frosts and slight thaws throughout six months have been most trying; and such things as Brussels Sprouts, Broccoli, Borecole, Kale, and Spinach have suffered severely. Parsley is entirely killed out of doors, and the sharp frosts and keen east winds of the present month have played sad havoc with our plants for the spring, little snow having fallen to protect them. The hardest frosts we had in December was on the night of the 10th

when the thermometer registered 23°; in January, 22°, on the 7th; in February, 18°, on the 9th; whilst the readings every morning for the present month are as follows:—1st, 4°; 2nd, 4°; 3rd, 4°; 4th, 20°; 5th, 7°; 6th, 13°; 7th, 22°; 8th, 8°; 9th, 7°; 10th, 12°; 11th, 16°; 12th, 14°; 13th, 13°; 14th, 11°; 15th, 13°; 16th, 9°; 17th, 16°; after which a thaw set in, accompanied with rain, with every prospect of milder weather.—W. G. PRAGNELL, *The Gardens, Sherborne Castle*.

## DURHAM.

IN the county of Durham snow has fallen to the depth of several feet, the roads being entirely blocked, and that cutting and carting has had to take the place of the snow plough owing to the depth of the snow, and the latter was unworkable. Shrubs were crushed to the ground and partially broken. "On our cold damp ground vegetables are a perfect wreck, and at the present time are all under snow. Broccoli suffered from frost before the deep snow fell, and is now decaying or rotting away. Celery is in the same position, and Brussels Sprouts little better. The snow is still a foot deep over the garden, and the worst results are not seen. It is now snowing while writing, a heavy wet snow falling fast, with a north-east wind. Our frost, although not so severe as in 1879, 1880, and 1881, has been of a long duration, ranging from 5° to 23° of frost on most nights, and has done more harm to vegetables by its being accompanied by rain or snow than it otherwise would have done, outdoor work being at a standstill; seed-sowing, &c., is being carried out under glass.—J. HUNTER, *Lambton Castle Gardens*.

## FLINTSHIRE.

THE early part of the winter was not unusually severe with us, 16° of frost being the most registered; but we have had very severe weather since the end of February, and on the 1st of March a fall of 8 inches of snow accompanied by a high wind drifted it in some places to a depth of 6 feet. On the 7th the thermometer registered 22° of frost. As far as I can judge at present vegetation has not suffered much. I think the snow has protected it to a great extent.—JOHN FORSYTH, *Hawarden Castle Gardens, Chester*.

## GLOUCESTERSHIRE.

THE winter from the commencement of the present year has been severe and protracted, with but few days of anything like mildness. On the 6th of January we had a heavy fall of snow, and on the night of the 7th 22° of frost. On the 26th another heavy fall of snow took place, followed in a few days by cold rains. During February no rainfall occurred; cold easterly winds prevailed with keen frost. On the 1st of March we had a deep snow, much of which still remains (March 18th) on the north side of walls, roofs, and hedges. We had 20° of frost on the night of the 7th, and it has been severe and keen ever since. The effects of this upon vegetation is disastrous. Broccoli, Brussels Sprouts, Cabbage plants, &c., seem as if a fire had passed over them they present such a scorched and withered appearance; even Leeks, usually so hardy, seem almost in as bad a plight. A direct consequence, no doubt, will be a great scarcity of green food for a considerable time to come.—WILLIAM NASH, *Badminton Gardens, Chippenham*.

## HEREFORDSHIRE.

THE winter of 1885-86 must rank as the most severe of late years. On the 16th March snow was lying which fell fifteen days before, and more seems threatening. The frost which killed all bedding plants, &c., in September was the harbinger of a winter of unusual length. The autumn flowers were robbed of their beauty, and nipping frosts and piercing winds now retard the appearance of spring flowers. In 1884 the shrubberies, &c., here were a mass of Primroses, and Crocuses, Snowdrops, Hepaticas, and other spring flowers were in full beauty early in February, while now everything is nipped. The fruit trees remain quite dormant as yet, and vegetables as represented by the Brassicas are much injured. The drought of last summer prevented their making much growth then, and the frosts of spring have withered those that have struggled through the winter.—CHARLES DENNING, *Holme Lacy Gardens, Hereford*.

## HERTFORDSHIRE.

WE have had almost continuous sharp frost and snow since the 6th of January. The greatest number of degrees of frost have been—on January 7th, 15°; January 8th, 22°; January 9th, 12°; January 19th, 14°; and 20th, 14°. The greatest number in February 6th, 12°; February 7th, 12°; February 8th, 13°; February 9th, 18°; February 10th, 18°; and February 24th, 12°; and March 4th, 12°; March 7th, 16°; March 8th, 13°; and March 9th, 12°. So far this year we have had only seven nights without frost; the last was on the 14th February. The frost is deeper in the ground at this time than it has been any time this winter.

We had a heavy fall of snow on 6th January, about 8 inches; altogether we have had about 16 inches.

The January rainfall with the snow was 3 inch, 30°; February rainfall with the snow was only 60°; March rainfall with the snow to this date 20°, which was a snowstorm on the 1st. The ground has not been quite free from snow since the 6th of January; neither has a lake here been quite free from ice since the same date. Vegetables have suffered very much, Broccoli mostly killed, and I am afraid autumn-planted Cabbages are the same. Spring bedding has suffered very much too; trees and shrubs have stood the frost well. They were well ripened in the autumn. Fruit trees are in a backward state. All kinds promise well except Pears.—G. NORMAN, *The Gardens, Hatfield House, Herts*.

## HUNTINGDONSHIRE.

THE winter has been unusually prolonged this year, and at the present

time vegetation is no more forward than is often the case in the middle of January. Although 15° of frost is the most that has been recorded, yet the temperature the last three months has averaged unusually low, standing at, or a little below, a few degrees of frost day after day. This week there has been at least 6 inches of snowfall. The majority of trees and shrubs look uninjured. Coniferæ seem all right, likewise fruit trees, but until a general thaw and change of weather sets in, it is not possible to tell what mischief may be done to rockery and herbaceous plants. Vegetables are getting scarce, and many hundreds of Endive and Lettuce have been spoiled by the alternate frosts and thaws. Broccoli look safe, but are smaller than usual. The reason of that is the previous summer being so hot and dry at planting time, and for some time afterwards.—A. HARDING, *Orton Hall Gardens, Hunts*.

## KENT.

THE following is an extract from weather observations kept in these gardens from October, 1885, to the present time, March 17th, 1886. In October we had fifteen fine days. On sixteen days we had very changeable weather, rough wind, fogs, rain and sleet. Highest temperature during the month, on the 2nd, 50°; coldest night was the 11th-12th, the glass went down to 23°. Frost on twelve nights during the month. Total of frost for the month, 37°. On the morning of the 24th we registered 1.40 inch of rain. Raining the whole of the day on 23rd, and very heavy rain at night, the greatest rainfall for any twenty-four hours in the year 1885. Total rainfall for October, 4.34 inch.

During November, 1885, we had ten fine days, nine foggy days, variable weather other days of the month. Very rough on the night of the 27th. Highest temperature on any day during the month was 54°, 29th; coldest night, 17th, the glass went down to 21°. During the month there was 84° of frost. The glass went below 32° on fourteen nights. Rain fell more or less on fifteen days. Total rainfall for the month, 2.70 inch.

December, 1885.—Number of fine days for the month, seventeen. Foggy, more or less, on twelve days, two very foggy. Very little sun during the month. Snow on the 27th and 29th. Very rough wind and rain storm on the evening of the 28th. Highest temperature on any day during the month, 48° on the 2nd; coldest night the 10th, the glass went down to 15°. The glass went below 32° on twenty-one nights. Total of frost for the month, 151°. Rain for the month, 1.04 inch.

January, 1886.—Fine days during the month, fifteen. Heavy fall of snow on the 5th, little snow on the 6th, 10th, 12th, 20th, and 22nd, and very rough wind and rain on the night of the 16th. A very rough month of weather. Highest temperature on any day was 48° on the 2nd; coldest night the 7th, when the glass went down to 12°. Number of frosty nights for the month, twenty-nine. Degrees of frost during the month, 215. Rainfall and melted snow for January, 1.54 inch.

February, 1886.—Old men working here say this has been the coldest February known in Kent since 1856. Nine fine days, very little sun; a month of cold, snow, sleet, hailstorms, and dense fogs. The highest temperature on any day during the month, 39° on the 2nd; coldest night was the 8th, when the glass went down to 15°. The only two nights without frost were the 14th and 15th, when the glass stood at 32°. Total of frost for the month, 175°. A very dry month, rainfall only 0.54 inch.

March, up to 17th.—Eight fine days, with bright sun, but very dry; rain very much wanted; we get a little sleet and snow and foggy mornings; the ground at the present time frozen as hard as a stone, general outside work at a standstill. It will be seen by the foregoing remarks vegetation is worse than at a standstill; everything outside getting less and less, Brussels Sprouts, Curled Greens, and I would like to say, Chou de Burghley, but it was all used last week. I must say one word in favour of the last-named vegetable. What I grew of it stood the winter well, and is an excellent vegetable eaten as a Cabbage last month. Veitch's Model Broccoli is standing the winter best; of Cabbage Ellam's Dwarf Early. The following is a total of frost registered here during February from 1879. February, 1879, total of frost for the month, 45°; 1880, 67°; 1881, 70°; 1882, 46°; 1883, 21°; 1884, 31°; 1885, 78°; 1886, 175°.—C. DAVIES, *Moat Park Gardens, Maidstone*.

## MIDDLESEX.

THIS has been the longest and most trying winter I ever experienced not that the frosts have been so intense as in some winters, but they have been more continuous. Up to the time the snow left us about the middle of February vegetation did not seem to be unusually cut, but since then the bitterly cold and drying east winds and the long-continued frosts have cut things up most severely. There is not a green crop that has not suffered, and some of them are killed.—J. WOODBRIDGE, *Syon*.

## NORTHUMBERLAND.

THIS winter will be remembered for the quantity of snow which has fallen, and the time which it has covered the surface of the country. From January 5th to this 16th day of March, snow has fallen on thirty days, and during that period the country has been covered with snow, with the exception of fourteen to sixteen days.

On March the 1st and 2nd the climax was reached, when it snowed incessantly more than fifty hours, with a heavy gale of east wind, which caused immense drifts, blocking all roads and railways and snowing up several trains from two to three days. Much of this still remains on the surface, and yet it comes as though we had had none, and the atmosphere is charged with snow, with no signs of abating except that the barometer is falling.

The frost has not been very severe in this neighbourhood (three miles

from the sea), 18° of frost being the lowest registered, but a few miles west further inland from 24° to 28° has been frequently experienced. Green vegetables, where exposed, are quite shrivelled. Wallflowers, and other spring bedding, where planted in the autumn and exposed, have collapsed. Fruit trees will be benefited by being kept hack—always an advantage in this climate, where late springs prevail. Roses have weathered the storm well. Evergreen trees and shrubs appear so far uninjured, having been sheltered by snow and a moist atmosphere, whereas when dry frosty winds prevail at this season great damage is done to the leaves. All labour on the soil has been suspended for three weeks, and the only seed sown outside are a few Peas and Broad Beans, and it will be a week or ten days now before anything can be done.—GEORGE HARRIS, *Alnwick Castle Gardens*.

## OXFORDSHIRE.

THE winter here has been a very trying one, not that the temperature has fallen so low as is often the case, but the cold has continued for such an unusual long time, and we have had E. and N.E. winds, which we feel much, being nearly 300 feet above sea level. Lettuce, Broccoli, Spinach, &c., are punished; many Broccoli are quite killed, and looking as bad as in 1881. Some Eucalyptus in sheltered places are looking as well as I have seen them, except in Cornwall. Many of our specimen trees are disfigured through having branches broken by the weight of snow on January 7th, and stone walls, gates, doors, &c., are showing the effects of weather more than usual. The soil was so dry last season that nothing could grow. Brussels Sprouts, Broccoli, and Kales are only one-third of their usual size. Of course, everything is very late and much behind, but the buds on Lilacs and other early shrubs look strong and well; so do all the bulbs.

We had 17° of frost on the 17th inst., and have been having from 5° to 13° every night during the past several weeks. We registered 27° one night in January. Springs did not reach their usual level till December. They were very high in January, and now we are getting dusty dry again on this bed of sand.—WM. HOVELL, *The Gardens, Headington Hill, Oxford*.

## SHROPSHIRE.

THIS has been one of the most sunless seasons that I remember for many years. There has been very few hours sunshine since the end of January, and very bad for those who have to get Grapes ready early in May. There has been sharp frost and snow, more or less, since 1886 commenced; but it has been more hindrance for work than destructive to plant life, and so far as I can see there is very little damage done to shrubs, Roses, and other plants, the lowest point reached being 22° of frost, which occurred on the night of the 6th and morning of the 7th of the present month. Our greatest fall of snow was in February, when there was 1 foot depth. Vegetation is quite dormant. The buds on Apple trees look more like December than the middle of March.

Our only consolation lies in the hope that when once it goes, we shall have spring upon us with a rush. The general crops of Peas and Onions, &c., are sure to be later than usual, owing to the lateness in getting in the seeds.—JAMES LOUDEN, *The Gardens, The Quinta, Chirk*.

## SUFFOLK.

FROM the commencement of the year the weather in this district has been almost continuously dull and frosty. The fall of snow has been slight. According to our register the temperature fell below freezing point on twenty-nine nights in January, 14° of frost being the lowest. The rainfall, including melted snow, is 2.73 inches. February was a drier month, only 0.28 inch of rain. The temperature still low; on twenty-two nights the thermometers showed frost, 14° being the lowest. As yet March opened with no improvement in any respect. Frost has occurred every night, 11° being the most. The rainfall to present date is 0.69 inch. Day temperatures from the beginning of the year have been correspondingly low, only on two occasions have the thermometers in the shade reached 50°. The wind has mostly prevailed from N.W. to S.E., and at times has been hitingly keen. The effect of the weather on green vegetables at this season has, without exception, been most disastrous, and as regards supply the mischief is felt all the more in consequence of the drought of last year that prevailed during June, July, and August, which on our light soils greatly retarded the preparation and growth of winter greens generally. Moreover, this drought was suddenly broken up in September by 6.28 inches of rain; this, with the weather that followed, seemed to check all further growth, and left a very sparse supply both in gardens and farms, a scarcity that is a good deal felt especially amongst farmers. Fruit bushes and trees are safe, being in a very backward stage. Ground work, tree-planting, &c., has been, and is still, retarded by the frost.—J. WALLIS, *Orwell Park, near Ipswich*.

WE have had the longest winter in my recollection, the frost has never been very severe. It has registered 18° several times, and once or twice 19° of frost. There has been several falls of snow, but none of them so heavy as has been experienced in different parts of the country. Very few nights have been without frost since January. Trees and shrubs have stood the winter almost uninjured, this I attribute in a great measure to the absence of sun while the trees were frozen. Vegetables of all kinds have suffered severely, especially Celery, Broccoli, Cabbages, Lettuces. Borecole and Cottagers' Kale are as fresh and sound as possible, and for a severe winter are the most useful vegetable we have. I believe this is the general condition of vegetables in this district. Fruit trees of all kinds are as backward as in January.—THOS. BLAIR, *Shrubland Park Gardens*.

## SURREY.

I BEG to submit the following items on the weather and its effects:—Height of Holmury above sea level, 550 feet. Eucalyptus, killed; Sweet Bays, Laurustinus, Euonymus, &c., severely damaged, and it may be in some cases killed to the ground. Stocks, Wallflowers, Pentstemons, Antirrhinums, and other tender herbaceous plants nearly all killed. Winter Broccoli nearly all killed, and main crop of spring Cabbages quite gone. With regard to frost, I find we have only had six nights in the year without frost—viz., the first three days in January, and again on the 11th, 12th, and 13th of February. Thermometer ranging from 32° to 11°; wind direction since June 24th mostly from N.E. or S.E.; average frost since January 8° nightly. Rainfall for January, 4.52, of which 1.92 fell in snow; February, 0.74, of which 0.07 fell in snow; up to 18th March, 0.51, of which 0.06 fell in snow.—E. BAYMAN, *The Gardens, Holm-bury*.

## SUSSEX.

THE weather since Christmas has been the most remarkable that I ever remember. We have had frost and snow for a few days, then rain; one might have fancied we were in for a spell of good weather. Before twelve hours hard frost would set in, the wind having veered round to N. or N.E., then as suddenly rain again; for six weeks the weather was most changeable. For the past fortnight it has been very cold; wind mostly E. or N.E.; frost every night, varying from 8° to 17°, with occasional snow storms. I never saw vegetation cut up so much. Turnips, Swedes, Broccoli, Cabbage, Lettuce, Endive, and all kinds of greens look as if a fire had passed over them.

Spring flowers, of course, are very backward and look miserable—such as Pansies, Wallflowers, Daisies, Polyanthus, Myosotis, and many others, appear to be dead; in fact, everything looks seared, and I fear a great number of plants are past recovery. I do not think fruit buds are hurt yet; they are not forward enough.—GEO. W. BREESE, *Petworth Park Gardens*.

## WORCESTERSHIRE.

FROM the 1st of January until now scarcely a night has passed without frost, varying from 2° or 3° to 21°. Since the 1st of March the cold has been more intense, and accompanied at intervals by heavy snow-storms and strong easterly winds. Our evergreens, shrubs, and Conifers, such as Bays, Laurels, Laurustinus, Portugals, Magnolias, Euonymus, &c., appear none the worse, and I do not think will be. All fruit trees in this district promise well for a good bloom, and will be quite a month later in flowering than usual. Our Apricots last year were in full bloom at this date, now you are unable to discern the colour of the flower. In the kitchen garden winter-sown Beans and Peas have suffered very much, also young Cabbage, Lettuce, Cauliflower, and everything in a small or young stage. Broccoli, however, I think will, as a rule, prove to be unharmed.—JOHN AUSTEN, *Witley Court Gardens*.

## YORKSHIRE.

THE winter with us has been exceptionally cold and long continued. Early in January we had a very heavy fall of snow, and from that time until now we have never been entirely without snow upon the ground. Cold east and north-east winds have preponderated over nearly the whole time. One most severe frost was on the morning of March 7th, when one thermometer registered 10°, or 22° of frost. At the present date, March 17th, we have about 3 inches of snow, with cold easterly winds, still no signs of any change to warmer weather. Winter vegetables have almost disappeared from the open garden. Brussels Sprouts and Savoys have decayed almost to their core, and spring Cabbage plants, which at Christmas were large and strong, are now very small and almost lifeless, plants which were then small have now entirely vanished. Cabbage sprouts are quite killed, and spring Broccoli quite ruined. Hardy shrubs will not, I think, have suffered materially, although they now cut but a sorry figure. The wood of last year was, however, well ripened, and has consequently borne the long-continued cold exceptionally well. The buds of all kinds of hardy trees are yet quite dormant. Vegetation of all kinds will necessarily be very late indeed with us, and in all gardens around Sheffield green vegetables of any kind will be scarce for the next two months.—W. K. W., *The Gardens, Oakbrook, Sheffield*.

IN this part of Cleveland the past winter has been a remarkable one. Up to the end of the year the weather was mild and open. The new year was ushered in with frost and snow, and from its advent until March 18th it might be said to have been three months of frost and snowstorms. On referring to our weather record I find during this period that snow has fallen on no less than twenty-nine days, but the climax was reached on the 3rd of this month, when snow had fallen continuously for two nights and two days, the wind all the time blowing a gale from the North Sea. When we first went out on that morning snow was found to be from 1 to 3 feet deep, and in some places drifted to 8 and 10 feet. On the morning of the 7th we had 17° of frost, and for several days the maximum temperature did not exceed 35°.

It is too soon to say precisely what effect this severe weather will have upon vegetation. Already the young shoots of Laurustinus and Portugal Laurels are much browned, and some things, such as New Zealand Veronicas, Euonymus, and Japanese Privet, are killed outright, but most kinds of Conifers and evergreens are little or no worse. All green vegetables are much injured. Broccoli, with the exception of Veitch's Model, look as if they will never recover.

No outdoor work has been done since Christmas, and of course no seeds put into the ground, but we have sown large quantities of Peas and

Broad Beans in pots, also pans of Cauliflowers, Brussels Sprouts, Onions, Leeks, Parsley, and Lettuce. These have been duly pricked out in pots or boxes, and stood in cool Orchard houses and frames in order to fit them for planting out when genial weather comes. On the disappearance of the snow this day, March 20th, I find Snowdrops coming into flower; they are just five weeks later than last year.—J. MCINDOE, *Hutton Hall Gardens, Guisbrough.*

## ROYAL BOTANIC SOCIETY.

MARCH 24TH.

THE Society's first spring Show of the year was held on Wednesday last in the corridor and large conservatory, Regent's Park, and a pretty display was produced, many of the groups being the same as those at South Kensington on the previous day. The weather was fine, and there was a good attendance of visitors.

Amaryllises were well shown by Mr. James Douglas, gardener to F. Whitbourn, Esq., Great Gearies, Ilford, who was first with twelve plants, and was also awarded the Veitch Memorial medal and £5 prize for a dozen varieties. They were all very fine, the Memorial Amaryllises including Vesuvius, Calypso, Empress of India, Lady Hulse, Great Gearies, Red Gauntlet, Dr. Masters, Clarinda, Sultan, Sir Garnet Wolseley, Napoli, and Madonna. Some had two spikes of four flowers each.

Roses were staged by Messrs. Paul & Son, Chesham, and W. Rumsey, Waltham Cross, who gained the prizes for six specimens, the first being well grown and freely flowered, examples of such varieties as Madonna, Lacharme, Souvenir d'un Ami, and Souvenir d'Elise.

Deutzias were good, those shown by Mr. James Douglas, who was first with his six fine specimens, Mr. Eason and Mr. Wheeler following with smaller examples. Azaleas were neat, Mr. Eason having the best six half-globular specimens, well flowered, Roi Leopold, Roi d'Holland, and Van der Craysson being notable varieties. Mr. G. Wheeler and Mr. R. Butler took the other prizes, the last named showing very poor plants.

With twelve Hyacinths and twelve Tulips in pots Mr. James Douglas took the premier prize, showing good plants, but not quite in his best style. Mr. Eason was second in both classes. The nurserymen's prizes were awarded to Messrs. H. Williams & Son and H. R. Wright. Mr. Douglas and Mr. Eason were the prizetakers for Crocuses, the first-named having large pots full of bulbs. He also had the only nine hardy Primulas, being awarded the first prize. The prizes for Narcissi were secured by Messrs. H. R. Wright, H. Williams & Son, and James Douglas, all showing good specimens. Cyclamens were well exhibited by the St. George's Nursery Company, Mr. Wiggins, and Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, who were awarded the prizes as named. Hardy herbaceous plants were shown by Mr. James Douglas, who was placed first with nine good specimens, the second-prize plants being the worst we have seen gain a prize. Lilies of the Valley were admirably shown by Messrs. H. Williams & Son, Finchley, who were first with grand potsful, Mr. H. R. Wright, Lee, and Mr. James Douglas following. For twelve pots of bulbous plants Mr. T. S. Ware was first with a pretty collection, Chinese Primulas being shown by Messrs. J. James, H. Williams & Son, and J. Wiggins.

MISCELLANEOUS.—Mr. B. S. Williams, Upper Holloway, exhibited a handsome group of 150 Hyacinths, a large number of Tulips, Daffodils, and Lilies of the Valley (silver medal). Messrs. W. Cuthush & Sons, Highgate, staged an imposing group of Hyacinths and Azalea mollis. Messrs. J. Veitch and Sons, Chelsea, exhibited a magnificent collection of Hyacinths, with some new Amaryllises and other plants (small silver medal). Messrs. Barr & Sons, Covent Garden, showed a fine collection of Daffodils, Anemones, Snowdrops, Palms, &c. (small silver medal). Mr. T. S. Ware, Tottenham, contributed an extensive collection of Daffodils and other flowers (small silver medal). Messrs. Collins, Bros., & Gabriel, 39, Waterloo Rd., had a large collection of Daffodils and Anemones. Mr. W. Rumsey contributed three boxes of Rose blooms and several plants in pots (large bronze medal). Mr. J. Wiggins, gardener to W. Clay, Esq., Kingston, had a group of Cyclamens. Mr. J. James, Farnham Royal, had a group of handsome Cinerarias. The St. George's Nursery Company, Hanwell, had a group of Cyclamens (large bronze medal). Frederick Jacob, Esq., Stamford Hill, showed a group of Odontoglossums arranged with Ferns (bronze medal). Mr. Stephen Castle, West Lynn, Norfolk, was awarded a certificate of merit for baskets of Gros Colman, Lady Downe's Seedling, and Alicante Grapes, all very fine and well kept.

Certificates were awarded to the following:—Dendrobium Leechianum, from Messrs. W. Thomson & Son, Clovenfords; Cattleya Lawrenceana, from Mr. B. S. Williams and Messrs. Laing & Co., Forest Hill; Imantophyllum robustum Mrs. Laing, from Messrs. J. Laing & Co.; Narcissus General Gordon, from Mr. J. Douglas; Amaryllis Plato and Lascelles from Messrs. J. Veitch & Sons; Odontoglossum Pescatorei Vervaeianum, from Mr. E. Vervaeet, Mont St. Amant, Ghent; Amaryllis Clarinda, from Mr. J. Douglas.

## HARDY FRUIT GARDEN.

As buds soften and begin to swell much mischief is frequently done by bullfinches, which must be shot in orchards of large trees. Garden trees kept trim and small by pruning should be syringed with a liquor of soft-soap dissolved in hot water and some soot well stirred in it. This can be thrown over the whole of the trees by means of a syringe with a coarse

rose, so that every bud may have a coating of it, and so be rendered distasteful to the birds. If the weather is wet and stormy this dressing may be washed off, and it must be at once renewed, as the buds are never safe at this season of the year. We invite particular attention to this really important matter, for upon it may rest the success or failure of a fruit crop. Let all fruit trees planted last autumn be examined now to see if the soil about the roots is firm and fastenings to supports are secure. If mulching was applied to the trees at the time of planting, as it always should be, the soil will be undisturbed now, but without mulching there is risk of its being loosened by frost, and a newly planted tree cannot grow in loose soil. See that the stems of young trees in orchards under grass are protected from sheep and cattle by bushes or tree guards. We prefer a compact screen of fine bushes bound about the stems so closely that no harm can be done by hares and rabbits. These pests may be excluded from fruit plantations enclosed by fences by putting wire netting to the fence, but this is seldom done in the right way. To fasten a piece of netting of the ordinary width along the fence with the bottom just touching the ground, is a mere waste of time and money, for rabbits have no difficulty in getting both under and over it. To render such a fence really rabbit-proof, peg wire netting upon the surface of the soil at the foot of, and outside the fence, and continue the netting up the fence. If we thus cover a strip of soil 9 inches wide the puzzled rabbits cannot scratch a hole under the fence, and if the fence is covered to a height of 2 or 3 feet with netting, neither hares nor rabbits can jump over it. With a small ditch outside the fence we can do much to prevent jumping, and so avoid having the netting so high up the fence. If any of our readers suppose our note on this matter is somewhat elaborate, we may remind them that it is the exception, and not the rule, to find even so simple a thing as putting up wire netting done in the right way.

## FRUIT FORCING.

FIGS.—*Earliest-forced Houses.*—The early varieties, as Early Violet and Prolific, that were started in gentle bottom heat in November, will soon show signs of their last swelling for ripening; and this being the most critical stage in Fig culture checks of every kind must be carefully guarded against. To insure flavour a drier atmosphere and higher temperature with increased ventilation on fine days will be necessary, but withholding water must be gradual, and anything approaching dryness at the roots must be avoided. It is a good plan to give established trees in pots a thorough soaking with water a few degrees warmer than the bed, and then cover them with light mulching, as it absorbs moisture when the trees are syringed and gives off genial vapour for some time afterwards. Brown Turkey, the best Fig for any purpose, will not be quite so forward, though not far behind, and to these give good supplies of tepid liquid manure twice a week, syringing twice on fine days and once when the weather is dull. Give the second syringing in time for the foliage to get fairly dry before night. In mild weather keep the night temperature at 65°, 70° to 75° by day, with a heat ranging between 75° and 85° with sun, as Figs enjoy an abundance of heat and light and full exposure to sunshine. Stop and thin the side shoots, training terminals forward where space remains unfilled, and it can be done without shading the fruit.

*Succession Houses.*—Trees growing in inside borders will now require generous treatment in the way of liberal mulchings with good manure, copious supplies of water, and thorough syringing twice a day. Damp the paths and walls frequently, and keep the mulching constantly moist. Ventilate freely through the early part of the day, and close with a brisk heat about three o'clock in the afternoon.

*Late Houses.*—In most localities outdoor Fig culture is a precarious crop, but excellent crops of the finest varieties may be grown in unheated houses having a full exposure to the south. Plant the trees in well-drained narrow borders, either training the trees against the back wall and then down the roof a foot from the glass, or they may be planted in front and trained to trellises not more than 16 inches from the glass. The principal points in their culture are to keep them dormant as late as possible in spring, but when they begin growing the treatment should be generous. The growths must be kept thin and neatly tied up through the summer, with more freedom in the autumn, when the points will draw to the glass and be ripened by the warmth. In winter the border should have a mulch of some kind to protect the roots, and the branches must have a protection of mats or other material, as they are liable to suffer in times of intense frost.

VINES.—*Early-forced Vines in Pots.*—These having been well supplied with liquid manure and attended to with rich surface mulchings, will have the Grapes swelled to a good size and changing colour. It will be well to lessen the supplies of liquid manure, but it must be done gradually so as not to give a check; and though a drier atmosphere is essential, it will be best secured by allowing a gentle circulation of air constantly in preference to withholding moisture from the atmosphere, moisture not being nearly so inimical to early as to late Grapes, and it is necessary that the temperature be maintained at 60° to 65° at night, and 70° to 75° by day, keeping at between 75° and 85° through the day with sun, losing no opportunity of ventilating freely.

*Early Houses.*—Keep the borders inside supplied with tepid liquid manure, and mulch the surface with short manure, which should be constantly moist, sprinkling it as well as other surfaces at closing time, but open the house a little at the apex before dark to allow of the moisture escaping, and ventilate early, and increase it with the advancing temperature, reducing in like manner for the day at 80°, and in time to run up to 85° or 90°. Still allow moderate lateral extension as the best means of avoiding shanking through the encouragement given to the roots by the spread of foliage.

**Muscats.**—Those now in flower will require a light temperature and moderately dry atmosphere, and daily attention to fertilisation to hasten their setting. With fine weather there is no difficulty in running the house up to 90° with ventilation by day, and the roots being inside or warm, consequently active, the night temperature may fall to 65°, or 5° lower on cold nights. We have had Muscats set well in a night temperature of less than 60°, but the roots were in a corresponding temperature, and when these are warm Muscats set much better than when the roots are in an unfavourable medium. Where Vines are languid they may be relieved by the removal of a portion of the surplus bunches before they reach the flowering stage.

**Late Houses.**—Vines started in good time are making rapid progress, and will require daily attention in disbudding, stopping, and tying before the points of the shoots reach the glass. Where the semi-extension system is practised, stop at the second or third joint beyond the bunch, and then allow the laterals to extend until every part of the trellis is evenly covered with foliage. Train the shoots, however, sufficiently wide apart to allow the full development of the foliage; the leading growth may be allowed to ramble along the back wall. Inside borders must have copious supplies of tepid water. Shut off fire heat early on bright mornings, and use the syringe freely during bright weather. Outside borders that were uncovered when the Grapes were cut and bottled, or since January, will now require some protection from drying winds to prevent the roots striking down in quest of moisture. Fresh stable litter is the best for the purpose, as it will not shut off solar heat so completely as heavy mulchings, and unless the borders are poor heavy mulchings of short manure will be best deferred until after the Grapes are set and swelling.

**Ripe Grapes.**—The unfavourable keeping weather has been against the keeping of Grapes, but in properly ventilated rooms they have kept satisfactorily. Examine them twice a week for decayed berries, and when some of the bunches have been cut the bottles should be removed and a general overlook effected. Lady Downe's is keeping well, also Gros Colman, the latter little if at all inferior to a Black Hamburgh. Gros Colman is about the best abused Grape grown, on account of its poor quality, but started early or at the same time as mid-season varieties, and grown so as to ripen by the beginning of September and allowed to hang until January, by which time the berries will have lost their disagreeable earthy taste so characteristic of the otherwise fine Grape in imperfectly ripened and prematurely used specimens. All late Grapes require time to mature after ripening, but for Gros Colman it is absolutely essential.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

**Roses.**—The weather has been very unfavourable for spring planting, and those planted early in the winter present a very unhealthy appearance. Those laid in are in the best condition, and if the first favourable opportunity is taken of finally planting them, pruning at the same time, they will soon commence active growth. Care should be taken to preserve as many of the delicate newly formed fibres as possible, and any newly planted Roses will be benefited by the addition of fresh loamy compost to the old soil. Where they are planted in dry positions, such as against sunny walls or near shrubberies, plenty of short manure may be worked in deeply, and a surface mulching be given to these and all other newly planted Roses. Teas are generally supplied in pots, and now is a good time to plant them. See that the soil is thoroughly moistened prior to planting, and they will take more readily to their fresh quarters if some of the roots are carefully unloosened and laid into the fresh surrounding soil. Plants that are to produce extra fine blooms should, after pruning is completed, receive a liberal mulching of manure, and this will better retain its moisture and be less unsightly if the surface soil is first carefully raked or forked back and then redistributed on the top of the mulching.

**Pruning Roses.**—This operation will be later than usual, but as no active growth has taken place, when the Roses do start the shoots will, in all probability, be extra strong and clean. The long well matured shoots on the Maréchal Niel may be laid in to their full length, the spray only being cut back, and it may be a few of the shoots if crowded or badly placed. Gloire de Dijon may be pruned similarly to the Hybrid Perpetuals, having the leading growths shortened according to their vigour by about one-half of their length, cutting back all straggling side shoots to within four joints of their base. It is the neglect of this pruning and poverty at the roots that spoils so many valuable trees of this popular Rose. The Teas should also be freely thinned out and shortened back, or otherwise the young growths will become weaker every season and the bloom correspondingly smaller. Banksians bloom the most freely when the growth is not very vigorous, and hard pruning ought, therefore, to be avoided. Lay in the leading growths, thin out the spray and that remaining with the fairly strong well ripened growth, and which may be lightly shortened, will probably produce abundance of trusses. The white variety is the best, being also sweet scented, while the yellow variety is the most robust. It is also time to prune the dwarfs and standards in the open. In every case the centres should be well hollowed out and all useless spray be removed. The more weakly the growth of the trees the more need of severe pruning, and *vice versa*. Shoots of the thickness of a slate pencil may well be shortened to about the three buds, but stouter growth ought to be left from 6 inches to 15 inches in length, according to their vigour, while in order to secure or maintain a well balanced head, long, badly placed, or straggling growth should be cut with old wood attached back to well placed growth nearer the centre of the tree. The foregoing applies equally well to dwarfs as to standards, but if preferred the former may have the long shoots which frequently spring up from their base

lightly shortened, brought down, and firmly fixed near the ground with the aid of strong pegs. Thus treated they would bloom at nearly every joint. During the summer more strong shoots would spring up, and these should take the place of those previously pegged down.

**Clematises.**—Many thousands of these most showy climbers are annually planted, but yet we seldom meet with them in good condition, or at any rate after the first two or three years. They fail owing either to being starved at the roots or neglected altogether. They ought to be planted in a compost consisting of three parts good loam to one of old Mushroom-bed manure or a good substitute for the latter. Then if properly pruned and trained they rarely fail to bloom splendidly whether over archways, up pillars and walls, or rambling over the tops of shrubs much as the wild sort does in our hedgerows. All are supplied well established in pots, and now is a good time to plant them. It is not advisable to wholly shake the roots clear of the soil, but as many of them as possible should be carefully uncoiled and laid in the fresh soil. The soil should be well rammed about them, and if dry weather prevail a good watering should be given before the old balls of soil become very dry. The pruning of both young and old plants must vary according to the sections to which they respectively belong. Jackmanni is perhaps the best known; this and others of the same type, such as Magnifica, Flammula, Prince of Wales, Rubella, Star of India, and Tunbridgensis flowering on the young growth formed the same season. Consequently these should be freely cut back at the present time to near where the growths last started, and in this manner the requisite number of strong young shoots will be obtained, and which may be trained to where the bloom is needed—say in a mass over a window on the trellising of a balcony. The Viticella type, which includes Lady Bovill, Mrs. J. Bateman, and Thomas Moore, requires similar treatment, as these, as well as Lanuginosa candida, Lady Caroline Neville, Gem, and W. Kennet, flower during the summer and autumn principally on the newly formed growths. The Patens type, which includes Lady Londesborough, Lord Londesborough, Lord Derby, Miss Bateman, Sir Garnet Wolseley, Fair Rosamond, and Standishii; and the Florida type, this including Countess of Lovelace, Lucie Lemoine, and Duchess of Edinburgh, flower on the ripened growth formed the previous season. Consequently such should have all dead wood cut away, and the remainder thinned out where at all crowded.

## THE BEE-KEEPER.

#### USEFUL HIVES.

THERE is a great and totally unnecessary expenditure in the purchase of hives, which, good in themselves, of exquisite workmanship, ornate in design and perfect in every detail, present it is true a great contrast to many of the rough boxes if beauty alone is taken into consideration, which, however, care being taken to have the inside measurements correct, are quite as useful and much less expensive than their more meretricious relations. Beauty in design and work is not, it must be understood, despised, but as the manufacture of a perfectly finished hive takes much longer and requires a greater degree of skill in the workman than one more roughly completed, so much higher will the price of the former be than of the latter. Hive makers do not, in the majority of cases, taking into consideration the risks they run and the great outlay often necessitated, charge exorbitant prices for their appliances. Their prices are, it may even be said, moderate when we consider the time and skill bestowed upon the little palaces they turn out. What I desire to impress upon all readers interested in apiculture is, however, that we poor bee-keepers do not require palaces, but are quite content to use a hive of far less pretensions, and only require careful attention to detail in respect of measurement and fittings, and, this being given, can easily dispense with all useless ornamentation or tricky devices, which, when the hive is untenanted seem likely to assist the bee-keeper, but when the attempt is made by their aid to manipulate a stock are a source of trouble and annoyance. In these days of keen competition cheap yet serviceable hive are a *sine qua non* in every apiary, and a few shillings extra outlay on a hive may make all the difference between a balance-sheet showing success and one showing failure.

It has always appeared that one shilling for each standard frame is a fair price to give for a wooden hive. It is sufficient to ensure good workmanship and sound material, and these are perhaps the two essential points to which the greatest

attention must be paid by a purchaser. I am able to buy hives with double walls all round, floorboard, section crate ready for use, and roof of depth sufficient, it is true, for one crate of sections only, but the remedy for this defect can most easily be supplied at home; at this price and after testing such a hive for the last three years, with no attention bestowed upon it except an annual coat of paint, I am perfectly satisfied that such a hive is all that is required, and will last equally as long as any that it has been my fortune to come across in my visits to neighbouring apiaries.

There are numerous "best" hives in existence, so many that it is impossible to award the palm with certainty to any individual one; but of this I am convinced, that too much stress is laid upon the hive and too little upon the skill of the owner. What more can be desired beyond an ordinary hive of sufficient capacity? Do frames parallel with or at right angles to the entrance make so great a difference to the health of the bees? One credulous observer even ventures to hazard the idea that foul brood may be induced by the position of the combs, while others say that one position is more natural than another. But of such fanciful ideas no notice need be taken, except to hope that common sense will come to the rescue and lead those who hold such ideas from their untenable position. Perhaps the most crucial question in connection with hives is the merits of deep and shallow frames. It is said that bees on deep combs lie more quiet in winter than colonies on the shallow frames, and if this is true it is a decided advantage. But it is a matter of common observation that two stocks in hives of identical description, will, the one be restless and active, the other quiet and still; and of this more than one case has come under my notice this winter, which has been a trying one to bees, and in not a few cases fatal. If it was my intention to keep up a large apiary I should not hesitate to adopt the standard frame, not because of any particular virtue it is supposed to possess, but simply on the score of convenience, but whichever size is made use of every frame ought to be of the same dimensions and so interchangeable.

This year I am for the first time using a Stewarton of the improved type, and I have little doubt that it is a hive of great practicality; but the one doubt which has hitherto prevented my using it is the possibility of selling the supers at a fair price. As for using sections on it, it appears to be ill fitted for such a purpose, while on the other hand it is surpassingly perfect in its construction, if ordinary supers are used. But notwithstanding all that has been said and written about various kinds of hives it is still my opinion that a large straw Pettigrew is one of the most efficient of hives. If swarms are desired it gives the earliest and the largest; if supers are desired, sections or other supers can be obtained with great ease and in quantity; for wintering they cannot be excelled; for the cottager who has but little time to devote to bees they are the easiest to manage, the surest to give a profit, necessitating least outlay, a minimum of trouble, and the greatest satisfaction and pleasure.

It seems a forlorn hope to expect to persuade bee-keepers that a hive with fixed combs can be a profitable one. They like to play with their bees, examine them and pry into the secrets of the hive, and think they are increasing their profits. If they are content to follow where some unwisely lead, I can only lift up a solitary voice in opposition, and wait until a return is made to the old methods, and a fresh revolution in apiculture is announced. Already the American bee-keeper, with his accustomed shrewdness, sees the fallacy of moving single frames, and is introducing a hive by which with one movement only a whole set of frames may be manipulated, and this if I am not mistaken is a small cloud on the horizon, betokening a speedy change in the position taken up by advanced bee-keepers since the moveable-frame hive was first prominently brought into notice. Time alone can prove the right, and, if by a few words of advice the return of a wanderer is hastened to the more certain way to success my end has been attained.—FELIX.

## HONEY PRESS WANTED.

ALTHOUGH generally setting ourselves against the multiplication of bee-keeping appliances, we cannot help expressing the want we have often felt of a handy honey press. Small producers who cannot afford a honey extractor, and those who only use straw hives, know with what difficulty anything like a good article of strained honey is procurable. The usual plan of breaking up the comb and leaving it to drain through cheese cloth is only a degree better than squeezing it by hand. In either case, in spite of precautions, the pollen will get broken up and impart its unwelcome flavour to the honey; and the case is still worse when, as is the case of heather honey, the honey is too thick and heavy either to drain of itself or to be squeezed out without being heated.

In the case of heather honey, in fact, nothing but squeezing will separate it from the comb, the extractor being perfectly useless.

The Caledonian Apian Society for years offered a prize for an "extractor" for heather honey; but, so far as we know, no award was ever made. The only exhibit we ever saw for this prize was not an extractor, but a presser or ejector, consisting of a cylinder and piston—a screw press, in fact—which took a very small piece of comb each time, and was besides offered at a price practically prohibitive. No doubt it would work in its own way, but a first glance showed a radical error in construction—the comb had to be placed flatways in the bottom, and the piston on descending had to burst the whole of the cells at once, the honey from those in the centre having to find its way through all the ruptured cells to the circumference. No wonder a powerful screw was required.

We would suggest to our ingenious subscribers our own ideas of what a honey presser should be like, hoping that a serviceable article may be evolved ere long. In the first place it should be made to receive the comb so that the pressure may act on it edgewise—that is, in the plane of the midrib. Thus the cells would receive the pressure consecutively, and a gradual easy pressure would do. The cells would then burst as they ought, only at their cappings, and the honey escape without having to pass through other cells, some of them, it may be, containing pollen.

We would make it to take pieces of comb about the size of that contained in a 1 lb. section—that is, the sixth part of a standard frame of comb. For this purpose a strong receiver with perforated sides would be requisite, and measuring, say,  $5\frac{1}{2}$  by 4 by  $1\frac{1}{2}$  inches, and a piston or plunger of solid hard wood, only a shade less. The plunger should, we think, be easily worked by means of a lever like a small pump-handle, only having its fulcrum at its extreme end.

The other requirements are an arrangement for removing the crushed comb, convenience for receiving the honey as it is pressed out, and a simple framework to hold all in a convenient position. We have our own ideas as to how these details may be carried out, but doubtless these will suggest themselves to any who really understand what is wanted. We only add that the whole apparatus should be so cheap as to be within the reach of our average bee-keepers. From experiments already made we are satisfied that with such a press the honey would be of the purest quality. The single squeeze given to the comb in the position we suggest does not break up the pollen so as to mix it with the honey. Who is going to give us a cheap and reliable honey press?—W. R. (in *British Bee Record*).

[HONEY PRESSER.—SHOWS AND JUDGING.—That there has been a great amount of knowledge in bee-keeping diffused through bee and honey shows cannot be doubted, but on the other hand there has been a considerable amount of injustice at them no person but those interested will attempt to deny. At the first Crystal Palace Show held in London gross injustices were not only attempted, but carried out to the very letter by the managers. At the first Caledonian Apian Society held in Glasgow the Judges were allowed to adjudicate and award the prizes to their own exhibits, which is not only unjust but misleading. At that Show a prize was offered for the cheapest storifying hive; two competed for the prize, the one was entered at 12s. 6d., while the other was entered at 34s. 6d.; the latter was in no way superior to the former, yet it was awarded the first prize. We have seen much written and heard much spoken about adulterated honey. Two gentlemen, members of the British Bee-keepers' Association, whose names I mercifully conceal, acted as Judges at a show where I was present, awarded every prize with one exception to pure sugar, in spite of my warning that it was sugar, and it was afterwards proved to be sugar.

In one case I saw two different hives compete in different classes, and the one that obtained the first prize in class A was beaten by the same hive in class B. There was no difference in make or price of any of these hives in either class, and the Judges were the same. There was an objection made to the losing hive in class A that it was "too dear for general use;" but it so happened that it was 10s. cheaper than the other, and appeared in printed letters underneath the ominous words, "too dear for general use." In class A three hives competed, but there were fourteen in class B. In class C awards were made even more glaring. Some of the best hives were not even opened. Along with two other persons I officiated as Judge at a show where we had great difficulty in awarding the prizes to the most deserving through the interference of one of the Committee in charge, and because we would not be influenced by him he disallowed the opinions of the Judges to appear in the press. I observed he took a special interest in bee furniture, and busied himself in recommending it to customers.

If shows are to be productive of good they must be conducted on equitable principles, and the judges appointed above suspicion, having a thorough knowledge of what they adjudicate on. "Honesty, justice, and truth" should be their motto, without which, and in the absence of any of

these properties, the shows will end in failure, and be a source of discontent, acrimony, and animosity, and will otherwise totally defeat their object.

In the report of the Caledonian Apian Society which appeared in this Journal, July, 1884, it was shown that the prize for a heather honey-extractor was withheld because it was not an extractor but a presser. I believed at the time, and my opinion is not altered, that the prize was withheld through prejudice or ignorance. Upon this subject the article prefixed to these notes, taken from the "British Bee-keepers' Record" for February 1st, is misleading and untruthful. Bee-keepers who are acquainted with the subject will agree with me that the consumers of hand-pressed honey will hail with delight the departure from hand-pressing to the more cleanly and more profitable system of extracting honey by mechanism of some sort.

But what is an extractor in its proper sense? There are hundreds of ways of extracting, but the most difficult thing to extract from a prejudiced person is truth. Now I consider that whatever the means used to extract may be, if it performs the work it is an extractor. It will be observed that "W. R." does not hesitate to call the presser an ejector, which is a name more appropriate for the centrifugal machine than extractor, which "W. R." admits is right, but which is in reality neither more nor less than an ejector, which he admits the presser has a claim to. I know some little about the laws of motion and the effect it has on loose atoms, by throwing them off in a straight line until they are altered in their course by some intervening body, but I fail to see where centrifugal force has the claim of being an extractor, even so much as the presser has; the greatest difference being that the former preserves the combs from being totally crushed, as is the case with the latter. "W. R." says the price was "practically prohibitive." Why does he not state what the price was? and how does he know whether the price is prohibitive or not? seeing he has no experience with such useful instruments, which hundreds can testify by taking nearly the whole of the honey from the combs in a pure state free from pollen, and not, as "W. R." unjustly says in his third paragraph, "No wonder a powerful screw was required." When "W. R." gains experience in the pressing of honeycomb he will learn that to extract the honey a powerful screw is required, and that but in a short time hence he will be singing its praises, in the same fashion he is doing with tiering hives, which he not so very long since did all he could to disparage. When the honey press was adjudicated on it had written instructions attached. There are also instructions in my "Essay on Bees," as well as in back numbers of this Journal. Now why "W. R." tries to disparage the press by making the false statement after the publication of those instructions is best known to himself. For him to say "that it would work in its own way, but a first glance showed a radical error in construction, the combs had to be placed flatways in the bottom," is as great an error as can well be.

The fifth paragraph's suggestions have nothing to recommend them by the way of novelty or utility. The "pump handle" was suggested by Mr. Pettigrew many years since, and forty years ago I had such a machine, but had to add the screw before it would work satisfactorily. When any improvement is attempted in instruments or machines these must be built upon what was gone before, and not to go back fifty or more years, as "W. R." has done. Then teachers should stick to the truth and be in full knowledge of what they attempt to teach, and, above all, do not make misrepresentations and misstatements. The quality of the honey extracted by the press is of fine quality, free from pollen or its flavour, and where there are only 100 lbs. of honey to press will clear the price of the press.

Last year, after A had extracted all the honey he could from some three or four hives by the old process, Mr. B called at his house, saw the combs about to be consigned to the melting pot, requested him to be allowed to try his press on the drained combs of A, who consented. Mr. B set to work, and in a short time pressed out 50 lbs. of good honey, which would have been lost but for the "powerful screw." Any attempt to extract honey by the proposed plan to press out the honey with a "single squeeze," will be found on trial to be very defective. The Lanarkshire honey press is complete in every detail, possessing everything and more "W. R." suggests, which he knows, at least should know. I send herewith a letter from one of the most successful bee-keepers in England, showing how well he is pleased with it, which is but one of many similar, all of whom speak in the highest terms of praise of the presser. I would indeed be very sorry were it otherwise after what I have written about it, and advised so many to purchase one. I therefore hope that any person who is in want of a good and cheap honey presser will not be deterred from purchasing one by "W. R.'s" unfair and untruthful article. Believing in the fact that there are men of more experience than "W. R." at work, and better adapted to improve on the presser than he can be expected to be, or he surely would not have concealed his ideas. Before a man condemns anything he should first show his improvements, thereafter he has a right to criticise and condemn anything inferior.

In the last trial I made with my presser, after all was in readiness 12 lbs. of pure honey free from taint of pollen was canned in fifteen minutes, suggestive that the presser as it stands is a very efficient instrument, and will not be readily improved upon, neither will it be thrown out of repute by any such misrepresentations as made by "W. R." In the interest of all concerned, I advise them not to use sections when drained honey is the object, as "W. R." advises; but either frames or supers, as sections reduce the yield of honey greatly. I shall be glad to advise all bee-keeping readers of this Journal, as well as "W. R.," how to get along in extracting honey and all other matter relating to the apary, and

take this opportunity of doing so by telling them that a presser wrought with rack and pinion, which I have had, is cheap and much superior to a pump handle for extracting thick honey from combs, at least it appeared so to—A LANARKSHIRE BEE-KEEPER.

[LETTER.]

"The weather is very bad for the bees; yesterday especially was a very bad day, and many bees were lost. To-day again is very bright and warm in the sun, and I fear lots will find a frosty grave. I scarcely like to interfere for fear of making matters worse, but I have thoughts of trying to hang cloths of some sort in front of the hives to keep off the sun's rays. I think my stocks are so far very strong. Have you ever weighed your hives from time to time during winter to see exactly how much food they consume? I weighed some hives on October 1st and again on January 1st, and the reduction in weight was as under:—1, 4½ lbs.; 2, 7½ lbs.; 3, 5 lbs.; 4, 4½ lbs.; 5, 6 lbs.; 6, 4½ lbs. This shows an average consumption of about 5½ lbs. per hive for the three months of October, November, and December, or rather less than 2 lbs. per hive per month. This seems very little, but of course less is consumed at this time than at any other, as no breeding is going on and the bees are quiet. I have not yet weighed them for January, but intend doing so, and shall weigh them every month. I expect the consumption will increase very rapidly, for breeding will soon be general. When we get milder weather I shall be tempted to look into some of them, but I am a great advocate for leaving them alone. Will you some day let me know where I can get the best honey presser, like the one you kindly lent me, and the price?—FRANK TAYLOR."

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

Chrysanthemums (*F. W.*).—There is no better information on Chrysanthemum culture than has appeared in our columns. Possibly Mr. Iggulden's pamphlet might be of service to you, and it can be had from this office, price 9½d. post free.

Lifting Vines (*J. C., Somerset*).—As we have repeatedly stated, Wednesday's letters can only be answered very briefly if at all in the current issue. It is not necessary to dig up your Vines to see if the border needs draining. Dig a few "trial holes" 3 feet deep, and if the soil is not very wet at that depth the site will be naturally drained. If you dig up the Vines the roots must be laid in moist soil immediately, as if allowed to get dry by exposure to the air, either during the process of lifting or afterwards, much damage will be done that will not be easily remedied. If you lift the Vines you must act at once, every day's delay being dangerous at this season of the year.

White Cineraria (*W. G.*).—Your variety is a very beautiful one, and we should advise you to increase your stock. The safest way will be by offsets as you have done hitherto, but if the plants are grown quite away from other Cinerarias you might succeed in getting seed to reproduce the strain. Exhibit a plant at one of the leading horticultural exhibitions, or send a specimen of the flowers to one of the meetings of the Royal Horticultural Society's Floral Committee.

Twin Cyclamen Flower (*J. D., Thirsk*).—The flower is very peculiar, and seems to be the result of the cohesion of two blooms, a kind of fasciation which is frequently seen in other plants. The plant is certainly worth preserving for its singularity, and it will be interesting if the character becomes permanent.

Budding Apples (*Inquirer*).—Buds are inserted in the sides of the upright stems of the young stocks in summer, when the buds are formed in the axils and the wood a little firm, yet not so much so that the bark does not rise freely, both to enable the buds to be removed and inserted. This generally occurs in August, but more depends on the condition of the growths than on any mere date for performing the operation. The work

is done the same as in budding Roses, the insertions being mostly made on the shaded side of the stocks.

**Removing Roses (Fourteen-years Subscriber).**—If there is no stipulation in the lease relative to the removal of plants and trees it is questionable if your employer can legally disturb the Roses. It is not customary, however, for owners of property to enforce the law in respect to the removal of flowering plants that a tenant may have inserted, and an amicable arrangement can generally be made on an equitable basis. In the absence of any written agreement to the contrary, however, everything a tenant, not being a nurseryman or florist, may plant belongs to the freehold, and he has no right to remove even a row of Box edging.

**Camellia Leaves Curled (Cineraria).**—There is nothing whatever the matter with the green leaf you have sent, which is fairly good in substance and colour, while the marbling on the other is an accidental occurrence that cannot be accounted for. We have very little doubt that the variety to which you refer is imbricata, the leaves of which are usually more or less twisted, and we have often seen a few marbled on the most healthy plants, some of the blooms being occasionally marbled also. If the tub is quite full of roots top-dressings of soot and a sprinkling of bonemeal well watered in will be beneficial. When the drainage is effective, as it should be, and roots active, Camellias require much water. If you can remove a portion of the top soil without materially injuring the roots and add fresh compost, this would encourage the production of fresh roots. Turfy loam not containing lime, with a sixth of dried cow manure and a sprinkling of wood ashes and bonemeal, will be suitable for top-dressing, pressing it down firmly.

**Disbudding Vines (F. J.).**—When the laterals are firmly established in position and no longer liable to be broken in securing them to the wires, these laterals being about 18 inches apart, no fresh growths will be required between them, and it will be better for the Vines if there is none. Much harm is done by having too many growths from the main rods of Vines, this preventing the due expansion of the foliage, and when the leaves cannot develop under the full influence of light they cannot elaborate the crude sap supplied by the roots and store nutriment for the support of the Vines. Future growths are produced from the buds at the base of existing laterals after these are pruned in the ordinary course. We told you before to make sure of the safety of the permanent laterals before removing all the superfluous growths. You may pinch some of them if you wish provided the foliage of the others is not shaded or crowded. With good soil and attention Liliums with bulbs  $4\frac{1}{2}$  inches in diameter may be well grown in 7-inch pots, but as you are absent a good deal your plants would be less liable to suffer by want of water in summer in 8-inch pots. You may let all the stems flower, affording the plants adequate support.

**Decorative Fuchsias and Pelargoniums for Winter (An Inquirer).**—Your question is too vague to permit of a definite answer. Some varieties of Fuchsias are specially suitable for decoration as small plants; others as large specimens. Then there are double and single varieties, and so much dissimilarity in colour that half a dozen varieties that would suit one person would not be admired by another. In the trial of old and new Fuchsias at Chiswick last year the following were certificated as the best decorative varieties:—Single, light sepalled—Prince Alfred, Lady Heytesbury, Ellen Lye, Erecta Von Novelt, and Miss Bright. White corollas—Artaban and Berliner Kind, double; and Flocon de Neige, single; Salmon, Madame Aubin, Mrs. Rundell, and M. Dufanre. Single dark corollas—Dr. Sankey, Crimson Globe, Charming, President, and Minerva. Double dark corollas—Avalanche and Phenomenal. Possibly you have some of those, and you cannot err in obtaining the others. The following are six good single and six double winter-flowering Zonal Pelargoniums:—Ajax and Plutarch, scarlet; Octavia, crimson; Imogene and Swanley Gem, salmon; Kate Greenaway and Enrydice, pink. Doubles—Col. Flatters and Boule Noir, crimson; Mrs. Cardon, cerise; Lord Derby, pink; F. V. Raspail, scarlet; and Lord Mayor, purplish crimson.

**Shamrock (R. H.).**—The botanical name of this is *Oxalis acetosella*, the common Wood Sorrel, or Shamrock. The plant is a native of the moist shady woods of this country, Europe, and North America, and is one of the most elegant of wild flowers. It delights in retired shady woods, groves, and hedges, and flowers in April or May. It was called by the old herbalists Allelnja and Cuckoo's Meat, because, as Gerard says, "when it springeth forth, the cuckoo singeth most; at which time also Allelnja was wont to be sung in our churches." But Allelnja is merely a corruption of the Calabrian name Jnliola. The whole plant has a grateful acid taste, much more so than the common Sorrel, and is on that account used in salads and in sauces. In Lapland it is plentiful that Linnaeus says the inhabitants of that country take scarcely any other vegetable food than Sorrel and Angelica. The expressed juice of the plant is employed to remove spots and iron moulds from linen; and this it does by the great quantity of binoxalate of potassa which it contains. Twenty pounds of the fresh leaves have been found to yield six pounds of juice, from which two ounces two drachms and one scruple of salt, besides two ounces and six drachms of an impure saline mass are obtained, and is sold under the name of salt of Sorrel and essential salt of Lemons.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (P. C.).—The Daffodil is *Narcissus incomparabilis*, the Eupatorium is *E. riparium*. (G. R.).—The numbers were not secured to the flowers, so that we cannot give them with the names. The white flower with red in the throat is *Dendrobium Draconis*, also known as *D. eburneum*. The yellow and brown spotted flower is apparently a small variety of *Odontoglossum luteo-purpureum*, and the other is *Coeogyne ocellata*.

COVENT GARDEN MARKET.—MARCH 24TH.

Trade very quiet. Grapes easier; also Strawberries. Cucumbers well cleared at low prices.

## MANGOLDS.

NEVER was there a spring in which the value of root crops could be more fully realised than that upon which we have just entered, and perhaps there never was a greater scarcity of roots since Mangolds came into general cultivation. We have had a long cold winter, and frost, snow, and keen nor'easters still linger with an icy grasp upon the land, so that all growth has been kept back, and we have had to maintain our flocks and herds with home-stored or purchased food, with very little help from pastures or other green crops. March and April are the months when our plans of a year ago for a provision of winter and spring food are put to the test. Let us therefore now look closely into results, carefully marking all faults and shortcomings, in view of doing all we can now to avoid failure in the future. Granted the truth of the assertion that we cannot command success full and ample in a calling so subject to and dependant upon the influence of the weather as farming undoubtedly is, yet it must be owned that by high and timely culture we may in no inconsiderable measure do much to avoid the injurious effects of unkind seasons.

Here, then, are one or two lessons which were again enforced by the disastrous drought which again prevailed so generally last summer. If you wish to do what is possible to insure a useful crop of Mangold sow the seed early in April in carefully prepared soil. The land must have sufficient drainage either naturally or artificially; it should be ploughed early and be free from foul weeds. The first week in April sow broadcast upon each acre of it a carefully prepared mixture:  $\frac{3}{4}$  cwt. nitrate of potash,  $1\frac{1}{4}$  cwt. nitrate of soda, 2 cwt. steamed bone flour, 1 cwt. ground coprolite, 1 cwt. common salt. Stir this well into the surface with harrows or expanding horse hoes, and then make furrows 2 feet apart with double-breasted ploughs for farmyard manure, of which 14 tons per acre is the quantity given by a high authority. Farmyard manure is such a greedy absorbent of water that we consider the measurement of any quantity of it by weight a mistake, and in this instance it is better for practical purposes to say that the furrows should be about half filled with it. Following the manure carts come the double-breasted ploughs under the middle of each ridge, throwing the soil into the furrows over the manure on each side of it; the seed drill follows, inserting the seed along the top of each ridge, the soil on the tops of the ridges being immediately afterwards pressed by a light roller. The seed is thus left to germinate in deep soil well stored with fertility. A free strong growth follows germination, and it is well sustained as the plants gain size, for the roots soon go downwards into the farmyard manure, finding there gaseous food to promote growth, and moisture to sustain it in unchecked vigour through all the vicissitudes of heat and drought.

Compare this well-tried system of ridge culture with sowing on the flat, and surely the advantage must be seen at once to be so clearly in favour of the ridge that general preference must be given it. We have had objection taken to the cultivation of Long Red Mangolds on the score of shallowness of soil, and that the huge roots absorb so much nutriment from the soil. We have proved in our own practice repeatedly that ridge culture meets the shallow soil difficulty, and it must be owned that the Long Red gives as well as takes, its great bulk affording us an ample return for what extra nutriment it may absorb from the soil, if indeed it does so. It is quite possible, or rather it is absolutely certain, that the numerous large leaves of this particular sort of Mangold derive much nutriment from the air; and we again remind our readers of the important fact that 93 per cent. of plant food is derived from the air. Let it also never be forgotten that the soil is a medium for conveying food to plants. It absorbs nutriment to be taken up by the roots, and we have only to replace that nutriment in it for the next crop very much in the manner already described in this paper.

If, however, objection be taken to Long Red Mangolds on the score of size, what are we to say to that favourite sort of Eastern County farmers, Yellow Globe? In Messrs. Webb's new catalogue they figure huge globular roots labelled with weights ranging from 41 to 47 lbs. each; they also tell us of roots of Long Red reaching the extraordinary weight of 62 lbs. Well done! say we; and instead of shrinking from the cultivation of either sort, let us see in the coming season if by high-class ridge culture we cannot approach these sensational results. Depend upon it, the roots of every sort of Mangold will be of a size proportionate to the condition of the soil and the system of cultivation to which they are subjected. There are plenty of inferior crops of both Yellow Globe and Long Red to be met with every season, and in its way a crop of Mangolds affords as fair an indication of a farmer's ability as does a crop of Oats. Sow Oats in poverty-stricken soil, and you may have a crop in miniature 6 inches high at harvest time; sow Oats in fertile soil, and you may have the straw full 6 feet high laden with huge panicles of grain. This reasoning by the light of results holds equally true of Mangolds, and depend upon it good culture goes very far to insure a crop of good roots even in

the most unfavourable seasons. Let us have large roots, say we, and plenty of them, and we care not for a little exhaustion of soil in the production of them; nor do we care to be hypercritical about the exact per-centage of water in such roots, for we only use them as a wholesome and fairly nutritious article of our mixed dietary for all the animals of the farm.

#### WORK ON THE HOME FARM.

Since writing our last note corn-sowing and spring work generally has been kept in abeyance by the extraordinary duration of winter weather. No growth of meadow grass or Rye yet gives promise of food, even for the flock, and the strain upon our stored food continues heavy. We fortunately have ample supplies—so ample, that we have some fine hayricks for sale, but we have not been eager to sell, as notwithstanding the heavy hay crop of last year, prices must have an upward tendency now. We hear of such keen competition for any roots brought into the market that Mangolds have risen to 25s. per ton. Both ewes and lambs are looking remarkably well, notwithstanding the coldness of the weather. Careful tending and plenty of good nourishing food tells among them, and the forward lambs already give fair promise of early and profitable maturity. We expect no large profit, for assuredly we should not get it if we did, but we do strive to obtain quick returns upon capital expended, and are content if we can only secure a modest margin of profit. Our expenditure upon artificial manures mounts up in the aggregate to a considerable sum, but knowing as we do such an outlay to be both safe and necessary, we have no hesitation in making it. Only before doing so a careful inspection of accounts, and a calculation of our prospective receipts and expenditure till next harvest was made. The last batches of winter pigs will be sold in the course of the next week or two. These pigs were not sold as porkers, owing to their large frames and tendency to grow fast rather than to fatten quickly into the nice compact chubby little pigs termed "Londoners" in the south-eastern counties, from the eagerness with which they are bought up for the great metropolitan meat markets. The larger pigs keep over, for bacon pigs sell for about £4 apiece, and are profitable, though slower in ripening for market. We desire to part with all of them now, as we have so many batches of spring pigs requiring the sty. As we have before said, it is a profitable and wise course to keep pigs to eat inferior corn, but the idea is no new one, for what says old Tusser?

"If vent of the market place serve thee not well,  
Let hogs up a-fattening, to drover to sell."

Among farm buildings recently erected we have had a nice snug range of stys built for breeding purposes. Advantage was taken of an angle on the south and west side of two old buildings, and so the expense of a back wall was avoided. A roof of corrugated galvanised iron, boarded sides, fronts, doors, and partitions, floors of burnt clay rammed hard, and all the woodwork dressed with hot tar, comprise the chief details of a cheap and useful range of buildings. We have on one of our farms a large commodious lodge, divided into convenient pounds, with a passage between them and an open yard in front of it. No doubt it is all very nice, but we regard such a building for pigs as both wasteful and unnecessary, and we certainly cannot afford to indulge in any such waste of money upon mere appearance.

SPRATTS PATENT.—We are desired to state that this firm has opened a sale room at 4, Great Tower Street, City, E.C. The room is in direct telephonic communication with the works, and contains samples of the various foods, medicines, and appliances.

#### REMARKS.

14th.—Cloudy, with a little sleet about noon.  
15th.—Cloudy morning, bright afternoon, snow in evening.  
16th.—Cloudy morning, with flakes of snow till about 11 A.M., then fine with some sun.  
17th.—Fine, with sunshine in morning.  
18th.—Overcast early, bright till noon, slight rain later.  
19th.—Fog till 11 A.M.; fine, bright, and warm till 2 P.M., then cloudy with rain from 4 P.M.  
20th.—Overcast till about 10.30 A.M., fine after.  
On March 19th the minimum temperature was, for the first time for exactly a month, above freezing point, and on the 20th the earth 1 foot below the surface began to warm up, having fallen almost uninterruptedly from January 5th, when it was 41° 8', to March 12th–19th, when it was 33° 3' or 33° 4'.

### HIPPEASTRUMS.

**I**F old Donald Beaton was right—and it is questionable if any person living can prove him wrong in the matter—all the so-called Amaryllises that flower at this season of the year are Hippeastrums. Thirty years ago in describing a seedling exhibited by Mr. Snow, gardener to the Earl de Grey, at one of the Horticultural Society's meetings, the "Grand Old Gardener" observed, "It is a soft shade between scarlet and crimson, the midrib of each petal being banded with white, denoting a descent from *H. rutilum* and some variety of Johnsoni. Every Amaryllis-like flower with a white band in the middle of the petal is some variety of Johnsoni, the oldest of all these crosses being the issue of *H. regium* and *H. vitellinum*." Mr. Snow's variety was pronounced desirable on two grounds—first, because it was "deliciously sweet in a scentless family;" and secondly, because of the habit—"the leaves coming up half-height simultaneously with the flowers—a not very usual occurrence with this group." He who recorded that "true Amaryllises only grow in the late autumn and through the winter in Europe, while Hippeastrums are under the gardener's control and may be managed to grow at different periods."

A great deal has happened since Mr. Beaton concentrated his attention on this order of plants, and what was regarded as unusual in 1855 is apparent enough now, for a few days ago the forest of spikes in the gorgeous collection at Chelsea were springing from what cannot be better described than an undergrowth of leaves coming up "half-height" with the flowers. Until within the last year or two the bulbs were leafless, and had been leafless for months. They did not "grow in the winter," but were in a state of complete rest, while they were quite under the "gardener's control," and could have been forced into growth at the will of the cultivator.

As it is certainly very desirable that flowers should have the accompaniment of the foliage of plants producing them, an advance has been made in Hippeastrums, for as a rule in the case of plants well managed the flower stems are only in advance of the leaves about a week or so, and when the former are fully developed and the blooms expanded the foliage is about half-height. A grand advance has also been made in size, substance, and symmetry, with richness and diversity of colour; but the other noteworthy virtue above alluded to, "scent," is lacking. If to the magnificent varieties of the present day could be added a "delicious sweetness," hybridisers who have accomplished so much would crown their efforts, for it would almost appear as if there was little room for improvement in other respects. As regards size, a flower 9 inches in diameter, stout in proportion, dazzling in colour, and admirable in form, ought to satisfy even persons of an exacting turn of mind. Still, experts will strive for something better. If they cannot add perfume nor materially enlarge the size of the blooms they will not improbably increase their number. A few years ago

many of the then fine varieties only had two flowers on a stem. It is true that with larger bulbs and good culture some of those varieties subsequently produced three and four flowers from one scape; but there are scarcely any varieties that have not more than two flowers now, not a few having from four to six, many bulbs throwing up two stems supporting ten and twelve handsome blooms. One plant in the collection referred to had fourteen expanded flowers on two stems, not so large as some others—indeed, rather small in comparison; but that is of little consequence, for once a new "character" is fixed the skilled hybridist is not long in making up other deficiencies, such as size and colour. The materials are provided, and he may be trusted to turn them to the best account; yet when 800 plants are massed, the pots plunged closely together in tan in the central bed of a span-roofed house, and most of the plants having two stems, it cannot be said there is any lack of flowers; in truth, there scarcely appears to be room for more, and no one not having seen from 4000 to 5000 of the newest and most handsome Hippeastrum blooms grouped together as if forming a vast bouquet can form a conception of the extraordinary effect produced.

As an example of the colours and character of the flowers a baker's dozen of varieties may be glanced at as typical, not arranged in order of merit, but taken as they stood, in passing round the house. *Titania*, scarlet, deepening to crimson, and barred with white; flowers 6 to 7 inches in diameter, and models of symmetry: *Romula*, crimson, with a suffusion of violet; 8 to 9 inches, a magnificent variety: *Cymba*, maroon, shaded purple, barred white, rich and striking: *Triumphans*, dazzling crimson scarlet, immense blooms of great substance: *Etna*, fiery scarlet, with recurving segments; flowers 7 to 8 inches in diameter: *Juliette*, stately and splendid, ground white, flaked with crimson and scarlet; flowers of great size and substance, probably the finest of its type yet raised: *Garonne*, a fine flower, cerise, mingled with rose, rayed white; unique in its way: *Diomedes*, very dark crimson, of velvety richness; blooms 8 to 9 inches across: *A. F. Barron*, unsurpassed for the intensity of its crimson scarlet, and of excellent form and substance: *Ancona*, distinct, crimson, deeply shaded with violet, white rays: *Emita*, white and cerise, flaked; neat and attractive: *Dunholme*, a wonderful flower, 9 inches across; rich scarlet, veined with crimson, barred with white: and, as completing the long dozen, one of the smallest, yet richest, dark, free, and beautiful, *Lord of the Isles*, dense, reddish scarlet, shading to crimson, and delicately veined. Those will suffice to indicate the nature of the display, which extorted from a visitor whose long residence in America had enabled him to see all that is "great" there, and whose travels made him familiar with tropical vegetation, "Well, well! I thought I had seen most things worth seeing, but I never dreamt of seeing anything like this."

After flowering the pots are covered with tan, heat and moisture being applied to promote a strong growth of roots and foliage, then a warm dry atmosphere is maintained for the ripening process, and in the autumn the growth is gradually dried, the bulbs resting in a temperature of 50° in winter. In the spring they are shaken out, all the old soil being removed, repotted in turfy loam in 5 inch to 7-inch pots, plunged in a very gentle warmth, and brought steadily on in a temperature by artificial means of 55° to 60°. That is the treatment in a nutshell, and they are a credit to the grower, nursery, and nation.—EXPERIENTIA DOCET.

### THE CULTIVATION OF MELONS.

(Concluded from page 203.)

THE restrictive system is the one by which ripe fruits can be obtained in less time than with either of the others. It is also the easiest and best by which a constant supply can be maintained without a break during the Melon-growing months,

with only limited house room at disposal. This takes more plants than the others, as they must be placed about 16 or 18 inches apart. These are trained upright until they reach to near the top of the trellis and then stopped. The laterals as they appear are removed from the axils of the leaves below the first wire of the trellis. Those above this position are stopped at one leaf until the top ones are produced, and upon these the crop of fruit is set. It will thus be seen that the fruit is set on the first laterals towards the top of the plant. The shoots carrying the fruit are stopped one leaf beyond it, and all sub-laterals are removed as they appear. The lower laterals are not allowed to extend beyond the one leaf, so that all foliage the plants carry is fully exposed to light and sunshine, and thus the strength of the plants concentrated into the swelling fruits. With the earliest plants the first female flowers that show are fertilised, so that no time is lost. These are generally set towards the base of the trellis, and very frequently the same plants ripen them and then carry two other fruits on the top. The other plants have to bear a full crop, and the fruits ripen in capital succession if two or three different varieties are planted at the same time. We require a regular supply of fruit, and, therefore, place out about six plants each time at intervals of three weeks or a month, generally the former. From this number there is no difficulty in producing fourteen or fifteen fruits, some carrying two, others three, according to the size of the fruits. The house is a rather wide half-span with seven lights, and contains two rows of plants, one to the front and the other down the centre. This space is occupied with six different batches trained on the system first detailed, except the end plant in each row, which is trained over the walk under the seventh light on the modified extension system. From the number required there is no difficulty in obtaining about ninety fruits, while we have not been able to obtain the same number by about twenty on the modified extension system. On the restrictive principle we never attempt a second crop of fruit from any of the plants without it is the first one or two that bear the early fruits, but generally these are removed, others being planted. This is continued as each batch is removed until we are certain of continuing the supply as long as fruits are needed.

Melons may be grown in pots for an early supply of fruits, and under this system can be produced earlier than by any other means. The plants when ready may be placed in pots 14 inches in diameter and plunged in a hotbed of fermenting material. In this case the bed in the house would be better without the central wall previously advised. The pots should be placed upon bricks or some other similar firm bottom to prevent their sinking after the training upon the trellis commences. The cultivator will do well to adhere closely to the restrictive system.

The soil most suitable for growing Melons is fibry loam of a heavy nature that has been stacked for a few months to destroy the grass. If the loam is from a rich pasture it will not need any addition; otherwise a little decayed manure or horse droppings may be used with it, and about one 8-inch potful of soot to each barrowload of the soil. The last is very good in any case, and may with advantage be used whether the soil is rich or poor. Melons can be well grown in much lighter loam, but with this mix cow manure instead of horse droppings, also a per-centage of clay according to the texture of the loam. The best means of thoroughly incorporating the clay is to dry it and then reduce it to powder. The soil must be thoroughly warm and moist before planting. Either the whole of the soil the plants require may be placed in the bed or border before planting, or the piecemeal system may be adopted. The soil must be made as firm as possible, so that a sturdy growth instead of a quick soft one will result. I do not advocate top-dressing further than placing on the surface a thin layer of cow manure after the fruit has commenced swelling, and then the stems of the plants are never buried. In case a system of top-dressing is practised the collar of the plant should be slightly elevated above the

surface of the soil. The mulching of cow manure will be found of great advantage when Melons are grown in large pots.

Melons require liberal supplies of water; in fact, from the time the seed germinates to the time the fruit commences ripening they should never be allowed to suffer by an insufficient quantity. The system of keeping the plants dry at their roots while the fruit is being set may be considered obsolete. I have never found any benefit result from so doing, but on the contrary have had an attack of red spider. Water is not withheld when the fruits commence ripening, but with varieties liable to crack the fruit is cut and finished on a dry shelf. They are none the worse for such treatment for a few days—in fact, I think they are improved in flavour. While the fruits are swelling liquid manure may freely be given. Syringe twice daily to keep the foliage clean and the atmosphere moist until the fruit is ripe; in fact, no difference is made in the atmosphere even in that stage, or else some of the other batches of plants are liable to suffer. Do not syringe, however, for a few days while flowers are being set.

Ventilate daily after the season has fairly advanced whenever the weather is favourable, but avoid cold draughts. When a close system of culture is practised the foliage is thin and flabby and will not bear the force of the sun's rays, therefore shade of some description becomes necessary. On the other hand, when freely ventilated the foliage is thick, stout and leathery, and not only capable of bearing full sunshine, but will resist the attacks of red spider and other insect pests. We ventilate liberally during the day and maintain a temperature by sun heat of from 80° to 85°. The house should be closed early in the afternoon when the plants are syringed, and the temperature allowed to run up after closing 10° or 15° higher.

When plants are grown in houses trained up wires under the roof, it is necessary to support the fruits by the time they are half swelled, or they will break the shoot from which they are suspended. Nothing is better for this purpose than shallow baskets made in the shape of a saucer, or square pieces of half-inch board with two or three holes bored through them to prevent water resting between the board and the fruit. These are easily secured to the wires by means of thin cord or wire sufficiently low that the fruit can just rest upon them.

Melons are subjected to the attacks of aphides, thrips, and red spider. The two former are easily destroyed by fumigating with tobacco, two or three applications being preferable to one very strong. When this is done the foliage should be perfectly dry, but the floor and lower portions of the house moist. It is a good plan to apply a little shade for a few hours during bright sunshine the next day, and to keep the house moderately close. Red spider will not be very troublesome if the plants are freely supplied with water and liberally syringed; but should it appear it can be quickly eradicated by syringing the plants with a solution of softsoap and water, one ounce of the former to one gallon of the latter in which a handful of sulphur has been stirred. This should remain upon the plants for two or three days and then be washed off.

Perhaps the worst form of disease to which the Melon is subject is canker. This is brought about to a very large extent by the culture the plants receive. Burying the collar of the plant beneath the soil when potting, or by top-dressing, is in some instances the cause, other conditions not being exactly right. There is another disease which for some years gave me endless trouble, and which may be called "rot." This seemed to make its appearance so mysteriously that for a time I was puzzled to determine the cause. At closing time the plants appeared all right, but when the sun shone next day the foliage flagged, and upon examination the stem of the plant was found rotten between two joints, not near the collar but frequently 2 or 3 feet from it. The plants disappeared in nearly all stages of development by this terrible disease, and everything we could think of, as well as the

suggestions of others, were tried, but proved of no avail. At last the cause was discovered to be too low a temperature, although we grew them successfully in another small house with the same temperature, but the house was naturally drier, lighter, and in a much better position. However, the difficulty has been overcome by raising the night temperature 5°, and this disease at once disappeared.

There are so many good Melons that selecting the best is by no means an easy task. Perhaps the best flavoured of all Melons is Dickson's Exquisite, but it is rather shy and liable to crack. It is worth a place and cannot be well excluded. Other good green-fleshed kinds are Colston Basset, William Tillery, Eastnor Castle, Bayley's, and the old Beechwood. White-fleshed kinds, Conqueror of Europe, Best of All, and Cox's Golden Gem, the last being rather thick in the rind, but a splendid keeper; scarlet-fleshed kinds, Read's, and Blenheim Orange. For early work we prefer Best of All, which is succeeded by Conqueror of Europe. For frames the two named, Eastnor Castle and Scarlet Gem, are free hardy varieties.

### HYACINTHS.

[A Paper by Mr. Polman Mooy, read before the Horticultural Club, March 23rd.]

THE Honorary Secretary of the Horticultural Club has invited me to say a few words upon bulbs and bulb-growing in Holland, and feeling anxious to oblige the members I will endeavour to meet your wishes, but the subject has been treated upon so much before that I must request your kind indulgence.

Bulbs or flower roots have for over 250 years been grown and cultivated in the vicinity of Haarlem, and their cultivation has gradually increased in importance until it has reached its present position. Among the admirers and lovers of plants and flowers, bulbous plants have always found many ardent protectors. No doubt the great and constant advance which civilisation has made in nearly all quarters of the world has greatly aided to extend the cultivation of flower roots and increase the demand, even in countries where fifty years ago there was not a single bulb, and where Hyacinths and Tulips were nearly unknown.

An advantage which bulbs have over plants in general is, that they have nearly all a yearly period of rest, when they can without much fear of injury be packed and exported to the most distant places. An advantage worth mentioning is that after they have done blooming and have grown to their full maturity they require only to be placed in a dry locality, and for a considerable time require no labour or attention. A further important advantage of such bulbs as Hyacinths, Tulips, &c., is that by artificial treatment they can be brought to grow and flower several months earlier than they would do when kept out of doors and left to their natural development, which for winter-blooming makes them unequalled by any other family among living plants.

I must mention first of all the much-beloved Hyacinth, as being not only one of the most esteemed among bulbs, but also one of the most beautiful, although at the same time the most difficult in cultivation and the most expensive to bring to perfection. The name of this genus originated with the writers of antiquity. Hyacinthus, a beautiful boy, was the son of a Spartan king and the favourite of Apollo. Zephyrus, being envious of the attachment of Apollo and Hyacinthus, so turned the direction of a quoit which Apollo had pitched while at play that it struck the head of Hyacinthus and slew him. The fable concludes by making Apollo transform the body of his favourite into a flower that bears his name.

The Hyacinth is a native of the Levant, and was first introduced into England in the year 1596; but it was known to Dioscorides, who wrote about the time of Vespasian. Gerard, in his Herbal published at the close of the sixteenth century, enumerates four varieties—the single and double blue, the purple, and the violet. In that valuable book on gardening, "Paradisus in Sole, Paradisus Terrestris," published by John Parkinson in 1629, eight different varieties are mentioned and described. He tells us, "Some are pure white, another is nearly white with a bluish shade, especially at the brims and bottoms of the flowers. Others, again, are of a very faint blush; some are of a deep purple near violet, others of a purple tending to redness, and some of a paler purple. Some, again, are of a fair blue, others more watchet, and some of a very pale blue. After the flowers are past the stem bears a round black seed, great and shining, from which, after sowing and protecting, the new varieties can be obtained." During the 250 years that

have passed since the above was published there has been a steady improvement in the size, form, and colour of the flowers of this plant.

From the eight varieties of 1629 more than 4000 varieties have been produced, of which, however, the greatest number have become extinct or out of cultivation. Many have been thrown out to make room for the latest improved sorts, of which about 200 only are at present subject to extensive commerce.

The Hyacinth is a general favourite in the most extensive application of the word, and the varieties in colours of different shades from the purest white to the deepest shades of scarlet, purple, black, yellow, and violet, are fully equal to that of any other florists' flower. The Hyacinths are usually grown for forcing into flower in the dull cheerless months of winter and early spring, when their delicately coloured flowers and rich fragrance lend a charm not otherwise to be obtained. They are equally desirable for planting in beds or in the garden border.

When looking over the cultivation of Hyacinths in Holland, which I have studied practically all my life, I must say that very great changes have taken place during that period in the taste and opinions of what a good Hyacinth should be; and, as a matter of course, this change has considerably influenced the varieties which have been propagated and grown. About sixty to seventy years ago there was a taste in general for the double-flowering varieties, and more particularly for the flowers with dark or other coloured bold eyes or centres, and I remember the time that a few beds sold by public auction realised very high prices indeed, while the varieties thus sold are not to be found now. These double varieties were mostly very small bulb-producers, which fact contributed very much to their being neglected and to their loss of favour in public estimation; while the considerable increase of trade and (in consequence of this) also increased competition among nursery and seedsmen abroad, stimulated by the feeling of revival in all branches of trade at the fall of Napoleon, brought on a gradual alteration in the Hyacinth fancy, as every tradesman—excited by the competition of his neighbours—was looking out for the largest-sized bulbs among Hyacinths, basing their trade recommendation upon the general but erroneous belief of the general public that naturally the largest bulbs must also produce the largest flower spikes.

The small bulb-producing varieties, however beautiful they might be, could not at that time find buyers, and growers were then compelled to meet the alteration in public taste as quickly as possible, and as this alteration in taste came rather suddenly and much quicker than the slow growth and propagation of the desired sorts could meet prices at that time rose wonderfully high.

In this run after large bulbs among Hyacinths many sorts with very inferior flowers were brought out in quantity; but although these large bulbs did increase the general trade, and so far gratified the tradesmen abroad by a greater sale and more profit, still they did not satisfy the amateurs, and better large flowers were looked after. After large-sized bulbs with large spike of flowers became the demand the single-flowering varieties have been found more capable of giving satisfaction than doubles, and when we compare the large spikes of the present day with the sorts we had sixty years ago we can only be well satisfied at the great progress we have been able to make. Although the double-blooming varieties are at present so much neglected, mostly because of their small-sized bulbs, there are some few double sorts which have pretty well maintained their position in public estimation, but their number is small compared with the large number of single ones in cultivation, and their very great beauty shall certainly keep them very long to remain the great favourites with lovers of very fine large flower spikes.

Among the esteemed double sorts I may mention Lord Wellington and Grootvorst, rose; Prince of Waterloo, La Tour d'Auvergne, and Florence Nightingale, white; Louis Philippe and Garriek, dark blue; Bloksberg and Rembrandt, light blue. Of the double yellow flowers Goethe is about the best, but most in this colour are rather of small spike. Of dark red among the double flowers there are only very few varieties, of which Louis Napoleon and Waterloo are about the best, but the latter sort is not so full as might be wished.

Among the single varieties we at present possess the greatest variety of colours, and among them we can now show superb large and handsome flowers, such as are Garibaldi, Pellissier, Scarlet Light, brilliant scarlet; Fiancée Royale, Gertrude, Koh-i-noor, Prima Donna, Von Schiller, red; Carlyle, Charles Dickens, Dr. Livingstone, Gigantea, Macauley, rose; La Grandesse, Alba Superbissima, Crown Princess, Madame Vander Hoop, pure white; Grandeur à Merveille, Baroness Van Tuyll, Mammoth, Seraphine, blush white; General Havelock, Baron Von Humboldt, Masterpiece, Mimosa, William I., black blue; Baron Van Tuyll, Charles Dickens, King of the Blues, Bleu Mourant, dark blue; Blondin,

Czar Peter, Grand Maître, Leonidas, Grand Lilas, Lord Raglan, light blue: L'Honneur d'Overveen, Sir Henry Havclock, Charles Dickens, Haydn, violet; Ida, King of the Yellows, La Citronière, Obelisk, Anna Carolina, pure yellow; Beauty of Waltham, Clio, Lamplighter, Lord Palmerston, Argus, flowers with striking eyes or centres.

All the varieties have been obtained from seed selected from thousands of seedlings and by artificial crossing and impregnations, which is an occupation of very long duration, as a little bulb grown from seed requires six or seven years before it is of sufficient size to produce a good flower; and when considering that this bulb if found worthy to be grown on requires twelve to fifteen or twenty years' careful artificial propagation before a moderate stock can be had, it may not create astonishment when many times new varieties have realised large sums of money. New varieties in almost every shade of colour have been saved from year to year, showing improvements in size of spike, in size of bulb, size of bells, &c.; but it may be worth remarking that in all the different colours we have obtained improvement in size of bells with the exception of the bright scarlet-coloured sorts, which until now have always turned out with small narrow bells. If we could obtain a Hyacinth flower of a bright scarlet colour like Queen of the Hyacinths or Garibaldi, with bells as large as La Grandesse or Cloche Magnifique, what a splendid improvement it would be, and probably in the course of time we may obtain this treasure.

Between the time when double Hyacinths were most esteemed and the time when single varieties came into favour, a period of perhaps ten years, the always increasing demand was greater than the general stock could furnish, and consequently the prices of Hyacinths grew higher every year, and it was at that time to be a rather profitable culture. This induced a great number of farmers in the neighbourhood of Haarlem to try growing Hyacinths, which many have done with more or less success. At that time land was worth only half the price that it is at present, and the most easy-growing Hyacinths were then artificially propagated to such a large extent that the stock overgrew the demand, and during the last three years forced the market price of such sorts down to such low prices, that during the last two years thousands of Hyacinths have been exported at prices below the actual cost of production, bringing great losses to the growers of this beautiful flower, while it overstocked the markets in several foreign countries where these bulbs were most used, to which poor circumstances the general depression in trade has of course contributed.

Respecting the use made of Hyacinths, I may say that the greater portion of the bulbs are being forced, and for this purpose the bulbs should be potted about the middle or end of September in 5-inch pots in rich light soil, and placed in a cold frame or under a wall, where they can be covered with wooden shutters or some similar contrivance to keep off heavy rains. In either case they should be covered a foot thick with newly fallen leaves, and being once well watered after potting they may be left for months to form their roots, when the most forward should be brought out (some repot into somewhat larger pots according to the apparent strength), and the bulbs should be placed in a gentle heat as near the glass and light as possible to prevent the flower stems rising to an unnatural height. Some care is necessary in the application of this, or the flowers will be abortive. It should not exceed 50° for the first three weeks, but afterwards may be increased gradually to 60°; and if the pots are plunged in bottom heat the same care should be observed, or the points of the roots will certainly be killed. One-third the depth of the pot is fully sufficient at first, and if the heat is brisk they should not be plunged more than a few inches at any time.

When the flower stems have risen to nearly their full height, and the lower bells of the spike are beginning to expand, the plants should be removed to a lower temperature usually afforded by the greenhouse, and when the bells are fairly expanded the plants can be taken to the sitting room or wherever their presence is desired, observing to protect them from sudden changes or cold draughts of air, and the water given to them should be moderately warm.

Instead of the usual practice of drying Hyacinths at once in the sun, I would rather recommend the method adopted in this country—namely, to place them side by side on a sunny piece of ground, and cover them with about an inch of loose earth to thoroughly ripen the bulbs by the subdued heat imparted to the earth which surrounds them. Left in this position for a fortnight they will become dry and firm, and an hour or two's sunshine will finish them properly for storing.

The propagation of Hyacinths can be artificially performed in two ways. (1) By the bulbs being cut crosswise and sprinkled with sand to absorb any superfluous moisture that may exude from the incisions. After a time they are planted in the earth in the usual way, when the mother bulb divides itself into small bulbs.

(2) By scooping out the base of the large bulbs after they have been taken out in July. After this operation it requires great attention in watching carefully the process of properly drying the wounded bulbs, because not proper attending to this the whole bulb may become mouldy and be lost completely. The bulbs thus treated are planted in October, at which time the small offsets at the base of the bulb are partly visible already, and are then planted in the usual way, only with a slight covering of earth in a warm situation as much exposed to the heat of the sun as possible, where the small bulbs gradually develop in the warm sandy soil, with the proper degree of moisture, aided by the climate, which about Haarlem appears to be so very suitable to the growth and development of this flower. (3) In the natural way by offsets from the parent bulb, which is, however, rather slow to meet the present large demand.

The Tulips used for forcing require about similar treatment as the Hyacinths. When placed in heat they should be placed as near to the glass as possible, in order to prevent the flowers drawing up too high, and the flower stems should occasionally be assisted when by their quick growth they get entangled in the foliage. During recent years Tulips have become great favourites for planting out in beds, for which thousands are annually employed, making by their very brilliant colours a very showy effect indeed. I could dwell for a considerable time upon the history of the Tulip and the very unusual speculation, or rather gambling, at some past period these have been made subject to; but if my present paper has given some little pleasure, it may induce me to try another on these and other sorts of flower roots at some future occasion.

I have no doubt that in several ways my present paper may be found wanting, but I may be allowed to remind you that as a foreigner I write in a language altogether strange to me. As an ardent admirer of horticulture in every branch, and stimulated by the earnest desire to do something to oblige the members of the Club, who may all be considered as lovers of horticulture, floriculture, and botany in every branch, I have ventured to write this short paper.

## ESTIMATES OF VEGETABLES.

**POTATOES.**—This is one of the most important if not the most valuable of all vegetable crops, and the most extensively cultivated; indeed, it ranks second only to cereals in economic value. The great value of the Potato as a crop to the grower for market and to those cultivating their own vegetables is its admitting of two crops of useful products being taken from the same ground in a season, which, however, only holds good of the early and second early varieties, and the most eligible are those with short sturdy haulm, being productive of an even-sized saleable crop of tubers, having few small, or chats, and good in table quality.

**KIDNEY POTATOES.**—Foremost as an early must be placed Veitch's Improved Early Ashleaf, which is by some considered identical with Kentish Ashleaf, and Rivers' Royal Ashleaf; but I have no experience of Kentish Ashleaf, and Rivers' Royal Ashleaf I find marked by a much stronger and longer haulm, and the crop is fully a week or ten days in attaining a profitable or marketable size. This means a higher value, and I have no hesitation in deciding in favour of Veitch's Ashleaf as the best early kidney. It crops heavily, the tubers are a good even size, with very few small, and brings a good per-centage higher value from the salesmen through its early maturing qualities, the young tubers even having a cooking quality that some others do not possess in a matured condition. Myatt's Prolific Ashleaf is, perhaps, the most extensively grown as an early crop. It crops well, but the crop is marked by a quantity of small tubers, which militate considerably against the paying qualities of the crop. Myatt's is much confounded with Veitch's, and in growth and shape of tuber they are similar, yet Veitch's has a more erect and slightly sturdier haulm, the tubers being more regular in size, more bulky, and the plant is distinguished by fewer haulms per plant, which accounts no doubt for the improved size and enhanced value. Amongst other early kidney Potatoes mention ought to be made of the Old Ashleaf or Early Dwarf-top, which though useful for frames and warm borders, as furnishing very early dishes, is of small value in comparison with others. Cosmopolitan is fine in form, productive, and excellent in quality. Mid-summer Kidney promises to be one of the very best first earlies, as the tubers are large, handsome, and good quality, combining great cropping with other valuable properties.

Of second early kidney Potatoes, Covent Garden Perfection I found a heavy cropper, the tubers being handsome in shape and a size that takes well with consumers, the quality good, and the plant healthy, being remarkably free from disease for an early, and the haulm, though somewhat more profuse than the

Ashleaf varieties, not very luxuriant, and on that account admitting of intercropping. Beauty of Hebron though a heavy cropper is not to be classed with a good cooking Potato, though it takes with rough-and-ready culture, and its corresponding consumers, similar remarks applying to Early Rose. In light and not rich soils the two last are much better in quality than in rich soil, and the bulk given in some measure compensates for loss of quality, and the returns from the salesmen are relatively good.

In late kidney Potatoes *Magnum Bonum* must take first position. It crops heavily, and is a good disease resister. Its quality is poor at best, but its cooking qualities are dependant in a great measure upon the soil. In light comparatively poor soils it attains a much better quality, and in many instances on hot sandy soils it is grown extensively and sent to market in succession to the early and second early varieties. A desirable main crop kidney Potato long wanted appears likely to be forthcoming in Welford Park, but I think much more highly of *Miss Fowler* and *Chancellor*, the two last evidently good disease resisters, but I have not sufficient experience of any main or late kidney, those I have grown failing in some essential characteristic. I have omitted *Lapstone* and its variety *Yorkshire Hero*, though for quality they are unsurpassed, also in cropping, but they are the worst of any for super-tubering and in liability to disease.

**ROUND VARIETIES.**—Early varieties in this section must be set down as nil, for though we have *Early Coldstream* there is not one round early at all comparable with the early kidney varieties in cropping or any other quality, though *Early Oxford* finds some favour with growers. In second earlies there is not much to be said in favour of the round, as for some reason these do not mature so quickly as the kidney varieties. *Sutton's Early Regent* is a capital succession to the early and second early kidneys; it crops heavily and is in every respect excellent, cooking firm and floury. *Dalmahoy* also is a capital sort for general use, and may be classed as a second early. To the latter type we are likely to have some grand additions in *Village Blacksmith*, a rough-skinned sort, sure indication of good cooking quality, and very productive; *M.P.* has a dwarf stout growth, crop heavy and very even in size—good useable fat fellows they are, as if they could not bear any small in their company, and the quality is good, improving with keeping, therefore is a main crop variety. *Chiswick Favourite*, with its strong haulm, ought to prove a great favourite alike with growers and consumers, but many novelties and certificated Potatoes, even trial ones, prove unsatisfactory when subjected to the treatment of ordinary varieties. Of the second early class *London Hero*, having a short haulm but spreading, and affording a large crop of flattish tubers, is promising, but for reasons above given I consider certificates for Potatoes most misleading.

Of main crop or late round varieties, *Schoolmaster* takes high place, but it does not succeed in all soils, it growing with me very coarse in rich light soil, and is very subject to disease. *Reading Russet* does better and is a good cropper of fair quality. *Victoria* also does badly with me through the land being rich, otherwise it is an excellent variety, and fine for the main crop. *Reading Hero* I find a great cropper, having large heavy tubers, which are of excellent quality, keeping in condition until the season is well advanced. *Vicar of Laleham* is a fine sort in the way of *Skerry Blue*, but is a seedling from *Victoria*, and though large in size and heavy in cropping is of first-rate quality. *Dunbar Regent* is unsurpassed as a late sort, cropping heavily, and suiting most soils. *Scotch Champion* need only be mentioned through its suitability for wet soils where other sorts would not succeed nearly so well, but its quality, like all others, is best in a good ripening soil, though much is accomplished by keeping. *Prime Minister* has large tubers, handsome, as good in quality as looks, and remarkably free from disease.

My selections are—early, *Veitch's Ashleaf* and *Cosmopolitan*; second early, *Covent Garden Perfection* and *Lapstone* (for quality); late, *Magnum Bonum* and *Chancellor*. Round—second early, *Early Regent* and *Village Blacksmith*; main crop, *Victoria* and *Chiswick Favourite*; late, *Vicar of Laleham* and *Dunbar Regent*.

N.B.—Where two are named the first-named should be selected if one only is wanted.—**UTILITARIAN.**

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 217.)

### PYRAMIDS.

CHRYSANTHEMUMS represented in the form of pyramids are highly effective when well grown, neatly trained, and profusely flowered. So-called pyramids are often spoiled by cultivators

attempting too much, and instead of their producing really creditable examples of culture we see tall attenuated columns not half furnished. Though small free-flowering incurved varieties, such as the *Rundle* family, are amenable to this method of training, *Pompons* are the best, and when produced as represented in the engraving, which is from a photograph, they are certain to be admired. The specimen in question (*Middle Marthe*) was grown and exhibited by Mr. A. Harding, and may be taken as an example of skilful culture.

For perfecting good pyramids strong cuttings are inserted in November. The best possible growth is encouraged, and the

Fig. 45.—Pompon Chrysanthemum.

plants placed into their flowering pots (8 or 9-inch) by the end of May. The leading shoot is topped at about 9 inches, the best shoot following being taken as a leader again, the side branches trained out regularly. A wire hoop about 18 inches in diameter is fixed at the base of each plant, supported by two crossed sticks affixed to the pot, a central stake of the requisite height being at the same time inserted. Smaller wires can be taken from the hoop to the top of the stake if desired; but good pyramids may be formed without by a judicious arrangement of the branches, securing them to the central stake and to each other. They must be topped as required for insuring a sufficiency of growths, the last time about the end of June in the case of the late-flowering varieties, the earlier sorts a fortnight or so later if all are desired to bloom at the same time.

As above indicated it is a mistake to attempt to grow the plants too large, it being far better to confine them to a fair size, say

3 feet high and 2 feet through at the base above the top of the pot. Continue to tie the branches loosely as they grow, as neatness in this form is necessary, and stakes cannot be used. When the flower buds show in September retain only the best on each shoot, and when these are swelling freely dispose them regularly, completing the tying as far as possible about the second week in October; then, if the plants are in the best of health, scarcely a twisted stem and no ligatures will be visible when the blooms are expanded, while the foliage will be dark, naturally disposed, and so dense that it will be impossible to see into the interior of the plant. If a pyramid can be seen through it is certainly imperfect.—E. MOLYNEUX.

#### NE PLUS ULTRA OR NORTHAW PRIZE BRUSSELS SPROUT.

MR. IGGULDEN, at page 227, remarks that these two Sprouts are exactly similar, and he is quite right. It would serve no useful purpose to go into details, but the public should know that the Sprout in question originated in these gardens, and that it was the desire of my employer and my own that it should be sent to Messrs. Veitch's grounds for trial. I also gave a pinch to a gardener, and I know how it found its way to Northaw, but why it should be sent out "direct from the grower" under the name of "Northaw Prize" is a question I leave your readers to determine.—G. MERRITT, *Gardener to Lord Daer, Kimpton Hoo, Welwyn, Herts.*

#### THEORY VERSUS PRACTICE.

IN a contemporary British gardeners have been held up to public ridicule on the grounds of their theoretical education not being equal to that of the foreigner. Some of our leading (so-called) scientists have a great liking for comparing us to our theoretical foreign neighbours; but in spite of our supposed ignorance I think we need not fear comparison as regards the results of our practice with the very best of these foreigners. If our critics would but condescend to visit some of our leading horticultural exhibitions and private gardens, and honestly compare them with continental horticultural exhibitions and gardens, I think that possibly they might not have much reason to be "pained" at our ignorance.

I have had the misfortune to work with foreigners, and have found that as a rule that they are quite up to your contemporary's standard—i.e., they are so well educated that, amongst other necessary acquirements (?) directly connected with gardening, they can "sketch flowers" and "speak and write more or less well some other language than their native tongue;" but then comes the poser—viz., that they come to this country "to work hard at the lowest pittance, disdaining neither the humblest occupation nor the lowest pay." Well, it may be my bad taste, but with all their "superior qualifications" I very much prefer an intelligent British novice to the best of them when our work is concerned. I may add that those with whom my lot has been cast have come from a foreign "National School of Horticulture," and are considered, I presume, "picked foreign gardeners." I am quite willing to admit that they have a "superior theoretical" knowledge of gardening, but in practice they are only fit to work with our beginners, and even then would not distinguish themselves for their industry. If foreign horticulturists are so superior to the Britishers, how comes it that the head gardener at one of the most noted places in France always employs English or Scotch as foremen in his principal departments, and, further, will not employ young men from the National School of Horticulture at Versailles? Then if botany and kindred sciences are so indispensable to practical gardeners, why is it that when a gardener—be he young or old—is being engaged he is never asked whether he has a knowledge of these sciences? The only inquiries made in nine cases out of ten are simply with reference to his "practical" experience and personal character.

In the article to which I have before alluded we find it stated that "matters of purely practical routine may very well be left to take care of themselves;" and yet this is what is chiefly required of us. A man who can do his work quickly, neatly, and well is the man who gets the best recommendation in this country, and deservedly so. It can hardly be disputed that the young man who cultivates an undue love of books and theoretical knowledge of his profession loses to some extent his liking for work—in fact, gets to think himself too good for work of a practical nature, and loses proportionately the character which is so much sought after—viz., "an active industrious man."

The old saying, "A little knowledge is a dangerous thing" applies very well here, as, to gain a knowledge of what we are told we are deficient in, we should be liable to neglect our real calling. We have to earn our living by the "sweat of our brow"—at least,

that is the lot of the majority of us, and therefore we must work accordingly.

Besides, what incentive is there for us to acquire all the knowledge spoken of? As I have before observed, our employers do not require it at our hands, and is it likely that we are ever to be bound to gain all this learning in order to obtain the salary of, say, £100 per annum, a sum that is generally considered good wages for a gardener? The fact is, a good practical man with comparatively little scientific knowledge is quite as able to satisfy the demands usually made on a gardener by his employer as one who "has a good knowledge of botany and physiology, chemistry, and can draw plans, sketch flowers, knows a little Latin, and speaks and writes more or less well some other language than his native tongue."—YOUNG PRACTICALIST.

#### A GERMAN ROSE SOCIETY.

A FEW particulars concerning our Rose Society may be of interest to some readers of the *Journal of Horticulture*.

During the Pomological Exhibition at Hamburg in September, 1883, a Society was formed for the encouragement of Rose culture in this country, when M. Schneider of Wittstock was elected President, who is well known here as the first proposer of the Rose election and as editor of a rosarian year book. For two years very little was heard about this movement, until last year the members met at Darmstadt and elected M. von Lade as President, M. Schultheiss Vice-President, and M. Strassheim of Frankfort Secretary. Since the 1st January the Society has published its own journal ("*Die Rosenzeitung*"), edited by the Secretary and sent out every second month. The first two numbers contain well written articles by the first growers, such as Gel Kettters, Schultheiss, Lambert and Reiter, Wesselhoeft, Warms, Jacobs, Koelle, and others; also two coloured plates of new Roses—viz., W. F. Bennett, and Her Majesty, and the names of over 700 members and thirty garden societies of late admitted. The success has during the short time been very rapid, and it is to be trusted that the encouragement will continue in such a good cause. The subscription is only 3s. per annum, for which small amount the members receive all papers published by the Society free, and also have free admission to all exhibitions arranged by the same; the latter are held at least once a year in different towns of Germany. The first Exhibition will be held in connection with the Horticultural Society's Show of Hamburg at the Zoological Gardens, from the 9th to 12th July. The programme is already published, in which 163 prizes are offered; of these seventy-two alone are for Roses. Among the prizes for Roses we may mention those for cut blooms of named sorts; for fifty and twenty-five each of Maréchal Niel, Souvenir de Malmaison, La France, Baronne de Rothschild, Horace Vernet, and Marie Baumann; for twenty-five of Catherine Mermet, Marie Van Houtte, Perle des Jardins, Etoile de Lyon, Madame Bravy, Madame Mel. Villermoz, Louis Van Houtte, A. K. Williams, Madame Victor Verdier, Captain Christy, Fisher Holmes, Jean Liabaud, Duke of Edinburgh, and Merveille de Lyon; for twenty of Lady Mary Fitzwilliam; for ten of Earl of Pembroke, Princess of Wales, Madame de Watteville, and W. F. Bennett. With great interest we look forward to the show of W. F. Bennett.

Another paper about Roses was started in July last; it is edited by E. Metz of Zwickau, Saxony, and published once a month at 6s. per annum. It contains some very able articles, and is illustrated with woodcuts.—ANDREW SPIERING, *Bergedorf*.

#### NEW v. OLD VARIETIES.

INSTEAD of misunderstanding Mr. Molyneux's advice, I think "S. B." and "Lathyrus" misunderstand mine. I am not so conservative as to imagine nothing will ever be introduced to surpass existing varieties.

I believe it is better for persons with limited means to wait for a year or two before growing the present season's novelties. By that time the worst will have disappeared from the catalogues, only the best remain, and these can be purchased at a reasonable price.

Of course in the case of a specialist, or a head gardener of long standing, where his employer does not object, nothing can be said against trying new varieties; but for a young gardener, or a man with insufficient means and labour, and where exhibiting is not the object, varieties that have been in commerce some time will answer the purpose as well as those costing four times the money.

The following is my vegetable seed order:—Broad Beans, Green Long Pod; Kidney, Light Dun; Beet, Dell's Crimson; Cabbage, Red Dutch; Kale, Dwarf Green Curled; Broccoli, Veitch's Self-protecting, Snow's Winter White, Adams' Early, Broccoli, Wilcove, Hill's June, and Purple Sprouting; Brussels Sprouts, Aigburth; Savoys, Dwarf Green, Curled and Early Ulm; Carrot, French Forcing Horn, and James' Intermediate; Cauliflower, Early London and Veitch's Autumn Giant; Endive,

Green Batavian and Green Curled ; Leek, Musselburgh ; Cabbage Lettuce, All the Year Round ; Onions, James' Keeping, Queen, Giant Rocca ; Parsnip, Hollow Crowned ; Radish, French Breakfast ; Mixed Turnip ; Peas, William the First, Laxton's Supreme, Champion of England, Ne Plus Ultra, and a few of Veitch's Perfection ; Spinach, Prickly and Round (this is optional, as the Round will stand the winter) ; Tomato, Hathaway's Excelsior ; Turnips, White Stone and Chirk Castle ; Vegetable Marrow, Long White.

I am sure if "S. B." had seen my Aigburth Sprouts this winter he would have said they were fit to exhibit, in spite of the dry summer and the fact that they were only watered twice. I have found the Peas named produce good crops of excellent quality ; and if I raised the seed bill to three times its present amount, I should most likely be told that the seed cost more than the Peas are worth. The seeds named can all be purchased at a reasonable price, and the varieties will suit a beginner till he finds out his employer's tastes and disposition, and fixes on a hobby for himself.—A. L. G.

## HINTS ON ORCHID CULTURE.

(Continued from page 229.)

### CULTIVATORS' ENEMIES.

ORCHIDISTS have abundance of enemies to contend with, for the plants are subject to the attacks of many insects ; but in this, as in other cases, prevention is better than cure, and a continual watchfulness for the first appearance of these pests and the adoption of prompt measures will save endless trouble. It is important to insure that the plants purchased are thoroughly clean, and if there be any doubt on the matter they should be well washed with tepid water and a small quantity of softsoap, sufficient to discolour the water, this being especially necessary for imported plants, the roots of which should also be washed in clean water. Orchids are subject to the attacks of most insects which infest other plants, such as green fly, red spider, thrips and scale of several sorts, and mealy bug ; while snails, slugs, woodlice, ants, and cockroaches also cause much trouble if allowed to become numerous. It is not difficult to keep a small collection clean, but where large numbers of plants are grown it requires constant care ; and in some establishments it is the rule to thoroughly clean the whole stock periodically, for delicate plants once a month. The frequent use of tepid water, softsoap in very small quantities, or weak tobacco water is the best means of keeping the foliage clean, applying the liquids with a sponge or camel's-hair brush. Green fly and the thrips may be destroyed by fumigation with tobacco or tobacco paper. Though this is commonly recommended it is a dangerous expedient in the hands of beginners, for a strong fumigation will often prove far more injurious than beneficial. It should only be resorted to in extreme cases, and then it should be given very moderately on several alternate nights ; choose a quiet evening, have the house drier than usual, and if moveable blinds are employed pull these down. Be careful to place the fumigator where the hot smoke does not ascend directly under any plants, and do not employ burning coal or coke, as the gases arising from these are very injurious. Slugs and snails must be looked after closely, a little bran being a good bait for them. A few cabbage leaves can also be laid about on the stages, and frequently examined ; hollowed potatoes, a little moss, and various other things serve as traps for woodlice. Ants may be caught in glasses of sugar or treacle and water sunk in the stages level with the material, or old bones can be placed about and occasionally plunged in hot water ; while for cockroaches I have never seen anything better than Chase's phosphor paste, which can be spread on pieces of paper, wood, slate, or any substance and placed at night where they are most frequent, removing it again in the morning. Isolating stages by means of metal saucers soldered round the supports and filled with water is an excellent plan, and the Orchid pan already noticed answers a similar purpose. There are several insects which are peculiar to Orchids, and one of the worst of these is that which attacks Cattleyas, causing the pseudo-bulbs to swell, and for which the only remedy seems to be cutting the growth away immediately it is seen to be swelling unusually. A useful little friend in the Orchid house is the green frog, which is a most persevering and voracious destroyer of insects, and two or three of them in a collection will save the cultivator a great amount of trouble.

The diseases of Orchids are few, and are principally due to excessive moisture in the air or at the roots, accompanied by unduly low temperatures. Many Orchids will continue healthy with very little heat, but the supply of water must be correspondingly diminished or decay of some kind will commence. That form termed "rot" chiefly attacks the pseudo-bulbs, but sometimes the leaves, and in any case the decayed portion must be cut clean out, dusting the surface freely with sulphur. "Spot," which appears on the leaves, has a similar origin, and the best plan is to alter the treatment as to heat and moisture, cutting away the worst leaves, or dusting them with sulphur. It is important to keep all material in a fresh clean state, providing a wholesome atmosphere by suitable ventilation.

—AN AMATEUR.

(To be continued.)

WE are informed that the annual POTATO SHOW AT THE CRYSTAL PALACE will be held as usual this year, but it will form part of the Company's programme for the season, the direction and arrangement being entrusted to the Superintendent, Mr. W. G. Head. Schedules are in course of preparation and will be issued as soon as possible.

— THE TREE FERNS AT CHISWICK which are being prepared for the Indian and Colonial Exhibition at South Kensington are making excellent progress. The large orchard house is devoted to the Dicksonias, Cyatheas, and Todeas, which present an array of these plants such as can be seldom seen. There are some particularly grand specimens of Todea barbara (T. africana), and one has been received at Kensington weighing two tons. A large example of this which has been grown several years at Kew weighed 15 cwt. when it was received, and another sent to Ham-burgh weighed 23 cwt., but that above recorded is probably the heaviest that has ever been imported to this country. Filmy Ferns, including numerous Todeas and Trichomanes, are also plentiful, and it appears that the representations of Colonial flora to be shown at the Exhibition this year will constitute an important and highly interesting feature.

— WE learn that Mr. R. I. Lynch of the Cambridge Botanic Gardens has translated "LES PLANTES DES ALPES" by M. Correvon, Director of the Jardin Alpin d'Acclimatation, Geneva, but that publishers do not care to risk its production. If those who would buy the translation will forward Mr. Lynch a postcard to that effect, he will publish it himself in the event of his receiving information of a sufficient number of purchasers to cover the cost. The price would be less than 5s. The original work has been a success, as might be expected from the author's experience as a cultivator, from his familiarity with the conditions under which Alpine plants grow wild. The value of the work rests in this unusual combination of knowledge. It has been written as a guide to culture, assuming that intelligent and successful cultivation must depend upon a knowledge of alpine nature. For this translation the author has written an additional chapter on botanising on the Alps, and it contains all that is found in the second French edition.

— THE summer Show of the CROYDON HORTICULTURAL SOCIETY will be held on June 30th, and the autumn Show on November 10th and 11th. The schedule of the first-named Show embraces 100 classes, the autumn Show 48 classes, and very good prizes are offered. His Grace the Archbishop of Canterbury is the President, and Mr. A. C. Roffey the Secretary of the Society.

— "L. G." sends us some remarkably well-grown samples of TABERNÆMONTANA CORONARIA FLORE PLENO, with the following remarks—"This is a plant that is not nearly so much grown as it deserves to be, especially where there is a demand for white flowers. I have a plant growing in the back of a Croton house. It is in a 14-inch pot, is about 4 feet high, and as much through. It is in flower quite nine months out of twelve, and during that time hundreds of flowers are gathered from it. They are much valued by ladies on account of their fragrance, which also makes them very valuable for buttonhole and bouquet making ; the only defect is their having such short stems that they have to be mounted on wire. The flowers should be gathered as soon as open, when they will keep fresh for a week. The plant is easily propagated by cuttings taken from half-ripened shoots. They should be placed in a moist bottom heat under a stand, light, or bellglass. The best soil is good fibrous peat and loam in equal parts. After the pots are filled with roots give liquid manure at every alternate watering. The plants must not be allowed to get dry at the roots, or the buds will fall prematurely."

— WE are informed that Mr. JOHN SIMONITE died on March 26th at Rough Bank, Sheffield, in his eighty-sixth year. He caught a chill three weeks ago, which brought on a severe attack of bronchitis, from which he never recovered. He was father of Mr. Ben Simonite, so well known as a cultivator and raiser of florists' flowers. Mr. Simonite was also a raiser and cultivator more than half a century ago. Much

sympathy will be felt in florists' circles for Mr. Ben Simonite, who had the help of his aged father in his garden up to the time of the illness which resulted in his death.

— GARDENING APPOINTMENT.—Mr. George Bates, late foreman at Calcot Gardens, near Reading, has been appointed gardener to A. H. Wood, Esq., Arle Bury, Alresford, Hants.

— WE are informed that the LUDLOW HORTICULTURAL SOCIETY will hold their Show on Wednesday, August 25th.

— Mr. H. S. EASTY sends the following note on THE WROXTON ONION:—"Perhaps it is rather late to recommend any variety of Onion for sowing, for I think when practicable February is the right month for putting in seed, but to those who are rather behind in their work—as indeed, so many are this year—I strongly recommend this handsome globe-shaped Onion as mild in flavour and an excellent keeper. I think those who give this variety a trial will not regret it, and with fair culture will obtain bulbs quite fit for exhibition. It is a quick grower and decidedly distinct, which is more than I can say of many new varieties. May I ask the readers of our Journal if they can tell me who is the raiser of this sterling novelty? for decidedly his light ought not to be hidden under a bushel."

— HORTICULTURAL CLUB.—A special dinner and conversazione was held on Tuesday, 23rd March, for the twofold object of welcoming some of the Dutch florists who had come over to the exhibition of Hyacinths and also to hear a paper kindly contributed by Mr. J. Polman Mooy of Haarlem, a member of the Club, on the Hyacinth. Those who had accepted the invitation and were present were Messrs. Massurel (Vervae and Co.), Ghent; Mons. A. F. Byvöert (Messrs. Byvöert Bros), Haarlem; and Mr. E. Kersten (Kersten & Son), Haarlem. There were present, besides, Mr. John Lee, Chairman; the Hon. and Rev. J. T. Boscawen, Dr. Hogg, Messrs. H. J. Veitch, Cutbush, C. Pearson, Consens, Hore, Girdlestone, Wheatstone, Van Waveren (Hillegom, Holland), &c. Mr. Mooy's paper was read by the Secretary, and is published on another page; it was highly appreciated, and an unanimous vote of thanks moved by Mr. Veitch, was desired to be conveyed to Mr. Mooy, and the hope expressed that he might be able to come over next year and read his promised paper on the Tulip. An interesting discussion followed, and a very pleasant evening was passed.

— THE monthly meeting of BELGIAN HORTICULTURISTS was held on March 22nd, when the following members were present:—MM. Vict. Cuvelier, Ph. Blanquaert, B. Spae, J. Hye, Desmet-Duvivier, Edm. Vervae, Em. Decock; MM. Van Geert père and Ad. Rosseel presiding over the two sections, and MM. A. Peeters and Art. Desmet were secretaries. Certificates of merit were awarded for the following plants:—*Imantophyllum* Mme. Vervae, from M. Vervae-Vervae; *Oncidium Jonesianum*, from M. A. Peeters of Brussels; *Azalea Vervaeana*, from M. Joseph Vervae; *Cypripedium Leeanaum*, from MM. Vervae et Cie.; *Odontoglossum Pescatorei Vervaeanaum*, from MM. Vervae et Cie.; *Odontoglossum Halli leucoglossum*, from the same exhibitors; *Cypripedium Sallieri*, from M. Jules Heye; and *Amazonia punicea*, from MM. Dubois et Cie. A cultural certificate was awarded for *Cypripedium superciliale*, from M. Jules Heye; and *Pellea ornithopus* var. *brachypteris*, from Mad. Ve. J. Vanderzwaermen. Honourable mention was accorded for *Cattleya Trianae magnifica*, from M. L. Desmet-Duvivier; *Clivia miniata Triomphe de Wondelghem*, from M. de Ghellinck de Walle; *Clivia miniata Triomphe de Gendbrugge*, from MM. Blanquaert et Vermeire; *Cattleya Trianae* var., from M. James Bray; *Azalea indica L'Ama du Cœur*, from M. Joseph Vervae; *Cypripedium Boxalli guttatum* var., from M. Van Geert père; *Odontoglossum mulus*, from MM. Vervae et Cie.; *Cattleya Trianae* var. *Popayan*, from the same; *Cypripedium hirsutissimum Vuylstekianum*, *Cypripedium politum*, *Anthurium Adriani* from M. Jules Heye.

— THE Committee of the Jacksonville Board of Trade publish in the *Florida Dispatch* some curious information anent PAPER CITIES for the benefit of the unwary. "The genesis of a 'paper city' is as follows: Some speculative person directs the attention of capitalists in New York, Chicago, Cincinnati, or elsewhere to the opportunity presented by Florida's 'hoom' and the general interest which is felt in the State throughout the country. They chip in a little money, send a man to Florida to prospect and buy a lot of land where they can get it cheapest and on easiest terms. Having bought the land they have it surveyed off into diminutive 'city lots,' get up flaming circulars, open handsome offices in some northern

city, flood the northern newspapers with advertisements, and sell their lots to people who have never seen Florida, and most of whom never expect to see it. No Floridian has anything to do with it, nor even hears of it, except through the northern newspapers, or through dupes, who, in their disappointment, anathemise Florida because they are deceived and swindled by northern speculators." The Committee go on to describe legitimate town building. "The site is necessarily chosen with reference to productions of soil and facilities of transportation. The lots in these towns are large enough to afford a yard around the house, a vegetable garden sufficient for the needs of a family, or a small Orange grove such as one man may care to look after. The object which the projectors of such towns set before themselves is to attract actual settlers, people who after purchase will settle and live there. Some of the most flourishing towns in Florida to-day, with a contented and prosperous population, have begun in this way, and such enterprises ought not to be confounded with 'paper cities.' These are genuine Florida projects; the others are alien schemes of outside speculators." The Committee conclude by saying that "Florida is not afraid of the truth. Much that is fanciful and exaggerated has been published about her in times past; much that is unjust and injurious is being published about her now. But we rest serene in the confidence that the truth will at last be established, and from that we have nothing to fear. Florida is not a land of lot-eaters, where it is always afternoon, and where a man can without labour reap the fruits of the earth and enjoy the fulness thereof. But it is a land where honest industry can rely with certainty upon reaping its just reward, and where capital finds unequalled opportunities for investment. It is also a land which, in spite of one freeze in fifty years, offers to mankind the balmiest and most benign of winter climates."

## HARBINGERS OF SPRING.

(Continued from page 218.)

MUCH has been said of the charming *Chionodoxa* or Snow Glory, though by no means too much. It is dwarf, 8 inches or so high, when established, resembling the well known annual *Nemophila insignis* in colour, but as its introducer, Mr. G. Maw, observed, "richer in colour." It is easily grown, a free bloomer, and a free seeder, admirably suited for the border, rockery, or for naturalising on grassy banks and slopes; and now we have another in *C. sardensis*, which is in flower; it is of the same habit of growth, but of a most intense blue, in fact a gentian blue, with a very conspicuous and clear white centre. It is little known as yet, but I think it will be equally popular as the first named, for which it will form a pleasing companion.

*Scilla siberica* has been long known in gardens, and is still as welcome as ever. Some fear it has suffered neglect since the *Chionodoxa* became plentiful, and which may to some extent be true, but it will always occupy a good position among hardy spring flowers. Just pushing through the turf is *Bulbocodium vernum*, with large Crocus-like flowers of a purple hue; it, too, must wait the departure of frost. Amongst the species of *Crocus* at this time we hail with delight the appearance of *Imperati aureus*, *Oliveri*,  *sulphureus*, *Wildeni*, and others, all of which form beautiful patches quite early in the year; even before the bedding forms have emerged from the ground. In *Ficaria grandiflora* we have a large golden yellow flower, a lover of marshy ground, and a most brilliant spring plant; and charming, too, are the hardy *Cyclamen*. Quite early in February come all the forms of *Atkinsi* and *Coum*, white, rose, and purple predominating. Pretty patches these form, and may be easily cultivated in cold frames, in pots, or in a sheltered rock garden nook. *Hepaticas*, too, are full of buds willing to unfold, but only one or two here and there are bold enough to face the frosty air. They all delight in a deep thoroughly enriched loam, and enjoy partial shade. In leaf mould they delight, and in abundance of sandy grit; they make quantities of roots, and a compost of these soils will suit them admirably.

The Windflower (*Anemone blanda*) will soon be in bloom. Lovely patches this forms in a little time; the blue is intense and so free-flowered that all who see it speak in its praise. In the herbaceous border in patches it is a gem, and equally so in the rock garden; while in the spring garden it is unequalled, rising about 10 inches above the surface. Not less conspicuous is the dazzling scarlet flowers of *A. fulgens*, which surpasses in its intense brilliancy that of the scarlet Zonal *Pelargonium*, and is one of the most effective of spring flowers. In mild seasons it comes late in February, though this season somewhat later than usual, and continues for weeks in perfection. It is a really noble plant in any position out of doors, and when grown in pots for conservatory decoration is equally striking. It is very free-flowering and quite hardy. It should for early spring-flowering be planted in September to insure its flowering early, and from this time, if planted at intervals, a succession may be had during spring, which many may prefer to one monotonous glare of its intense scarlet flowers. While this is yet in its prime come the varied Crown *Anemones* (*A. coronaria*), which, commencing in March, continue through April and into May. These represent many shades of blue, lilac, purple, rose, crimson, scarlet, and vermillion, are exceedingly double, large, and very handsome, equally adapted for spring gardening or

massing in beds generally, and certainly most useful at this season of the year for cut flowers. Nowhere have I seen forms of greater substance and brilliancy than at Belvoir, where they are grown extensively; they enjoy a well enriched soil of a loamy nature. Following these we have the golden blossom of *A. ranunculoides* and the lovely sky blue *A. Robinsoniana*; while still later come the form of the Wood Anemone and *A. apennina*. All these are beautifully adapted for naturalising, spring gardening, or the like, and make pleasing patches in any ordinary soil.

In turning to the Primulas, rosea, cashmeriana, and denticulata are among the first, soon to be succeeded by our native Primrose. There are many forms, single and double, all of which are valued in spring. They mingle well, too, with other flowers. Few, however, are of greater value than the acaulis section and those above-named for the earliest days of spring, and speaking of our wild Primrose reminds me of a charming companion it has in the blue Forget-me-not, which we all admire—I refer to *Myosotis dissitiflora*, than which we have nothing more deliciously sweet and elegant in all our spring flowers. A plant of easy culture, of easy propagation, and adapting itself to an almost endless variety of uses, it is a favourite everywhere. Daisies, red and white, now come in the category of spring plants; so, also, the early-flowered portions of bedding Violas. These are valued groups among spring plants which give variety to the garden and continue long in perfection. For spring gardens they should be planted early in October, and for summer beds may be planted at once. *Triteleias uniflora*, *conspicua* and *lilacina*—the former with its waxy-white flowers produced in the greatest possible profusion, and the latter with pleasing blue flowers equally free—continue for many weeks in succession early in the year? The Wood Lilies of North America, *Trilliums*, delighting in moist sandy peat in shady sheltered positions, are useful for spring. *T. grandiflorum*, *T. g. præcox*, and *T. g. maximum* are the best of the genus. The second-named is the earliest to flower, being succeeded by the other two; the last is a grand form, and quite the giant in every respect. To become well established all they need is to be let alone. This is coveted by numerous hardy plants, which do not readily establish themselves after being moved, and we find examples in the *Pæonia*, *Hellebores*, *Cypripediums*, with the group under notice, and many more, whose requirements are simple if grown on the let-alone system, and beyond supplying a liberal top-dressing of well-decayed leaf soil and old manure annually. When dormant these *Trilliums* may remain for years undisturbed, only to increase year by year in strength and beauty.

There are yet many more spring beauties, but which I cannot detail now, so many must be omitted. In passing, however, I would call attention to *Saxifraga Burseriana*, with its tiny glaucous, almost silvery compact tufts of Juniper-like rosettes studded with its sparkling white flowers on reddish stalks. The buds, prior to expanding, are of a ruby red, the successional ones contrasting most pleasingly with the already expanded blossoms. It is pretty for a sunny position, coming in flower from January onwards through February and March, only 2 or 3 inches high; it is a sturdy little plant. Later on we have the purple-flowered form of *S. muscoides*, a plant very effective in spring bedding, studded with its pretty flowers on mossy cushions, and with it the *Megaseas*, whose bold towering panicles of flowers render them conspicuous in spring. Some of the finest and hardiest are *ligulata*, having immense panicles of rose-coloured flowers, *cordifolia*, *purpurea*, and *Stracheyi* with spreading panicles of white flowers. But we have not long to wait ere *Leucojum vernum*, the Spring Snowflake, and *Erythroniums*, or Dog's Tooth Violets, so pleasing and quaint, the Vernal Gentian, and Wallflowers, Tulips, and innumerable spring-flowering plants will all be expanding. I have only named some of the most worthy of our earliest flowers of the year.—J. H. E.

#### PROPOSED INTERNATIONAL HORTICULTURAL EXHIBITION FOR 1887 AT SOUTH KENSINGTON.

[A paper read at the Royal Botanic Society's meeting last Saturday, by Mr. W. S. Manning, Woodlands, Maize Hill, S.E.]

It is most important this proposal should not be dropped for next year, because—

1st, It is much more certain of success if held immediately after the present successful series, the public having got into the habit of going to South Kensington during the summer.

2nd, The foreign exhibits would serve to offer valuable hints as to the most advanced systems and laws on the Continent regarding training in the rural schools; also as to the many kinds of market-garden produce and hardy fruits grown in North Europe, at present unknown here.

3rd, The crisis in the farming world has become so severe that no time should be lost in promoting any scheme that might aid in solving the knotty questions of agricultural distress, and in showing how land is profitably cultivated abroad. Our consuls could probably look up exhibits for this purpose.

4th, The allotments agitation and proposed land law reforms will tend to popularise such an exhibition, and it would serve to help in selecting the most lucrative crops for small holdings.

5th, We can best compete with America in our Apple-growing and with other foreign fruit growers when we see the finest and best paying varieties that are grown in climates like our own in Europe.

6th, Indirectly it will tend thus to relieve the terrible distress in the towns by promoting profitable spade culture and increasing food supplies in our rural districts.

7th, The Queen's jubilee may probably be kept next year, and this

exhibition, in its floral and festive elements, afford especially appropriate means of celebrating it.

8th, Whatever may be the difficulties in carrying out the scheme this year, they must be overcome whenever it is undertaken, and the guarantee fund would be most liberally repaid to if the above items can be all included in the project, so that all classes in the community may take a special interest in its success, from Royalty and our large landowners downwards.

The leading features in such an exhibition would be permanent and occasional shows. Amongst the latter a grand display of flowers from all Europe would probably produce the finest spring show ever held.

A series of similar shows for Orchids, Roses, Lilliums, Clematis, Coleus, and cut flowers will be held during the summer; shows of market-garden produce, with the most complete possible selection of the large varieties of Continental kinds, unknown almost at present here, such as Carrots of upwards of thirty kinds, Turnips of fifty-eight sorts, Haricots of seventy-five sorts, &c., salading, &c.

Every variety of fruit, especially of the best and most profitable Apples and Pears to keep up a regular supply "all the year round," can be shown from all parts, thus affording valuable opportunities of comparing notes, and enabling both producer and consumer to see what is done abroad in hardy fruit culture. Such fruits as Strawberries, already largely grown by our farmers, might be produced of sorts that would prolong the season, by planting a larger variety for successive supplies.

These educational and economic objects to be made the leading features, to show the best system of culture for small farmers, cottagers, &c. Specimens of such culture from all the more advanced States of Europe to be kept on show in successive relays, and similar exhibits from each of our counties in the United Kingdom.

The permanent shows would include fruit trees in pots, showing pyramid, bush, cordon, and espalier trees. Specimens of all fruits and vegetables, manufactured and dried, apparatus for canning, &c.; table decorations, window cases, vases, Palms, Coniferae, flowering shrubs, evergreens, plans for gardens, irrigation works, reservoirs, and aqueducts.

#### ORCHIDS AT THE FOREST HILL NURSERY.

THE Forest Hill establishment of Messrs. J. Laing & Co., so famous for its wonderful collection of single and double Begonias, will soon become noted for another speciality, a unique collection of Orchids. This enterprising firm has only recently commenced to form a collection, and within a short space of time has got together several large housefuls of select types of the various leading genera of these curious, but nevertheless beautiful flowering plants. The houses have, for the most part, been specially erected for Orchid growing, and are in every way thoroughly adapted for the purpose, as the present condition of the plants abundantly testify. A notable feature in the internal construction of these structures is the employment of galvanised corrugated iron, with iron cross bearers and uprights for the middle and side stages in lieu of wood and slate, as generally used. A layer of shell shingle is spread over the stages, and the firm speak highly of the advantages of the increased amount of moisture afforded by its retention in the channels of the iron in sufficient quantity to keep up a constant humidity in the atmosphere.

It is not, we believe, the intention of this firm to grow large specimens, but for those of moderate size suitable for general demand. Of *Odontoglossums* there are a vast quantity, representing the finest types of such species as *O. Rossii*, *O. Pescatorea*, *O. cirrhosum*, *O. Alexandrae*, *O. vexillarium*, *O. Wilckeanum*, *O. Londesboroughianum*, and *O. gloriosum*, many of which were in flower at the time of my visit.

The *Cattleyas* are looking remarkably well, many of which are flowering within a year of their importation. Among these are a couple of plants of that beautiful species *C. Lawrenceana*. The colour and substance of the flowers of one of these plants is unusually rich and good, its labellum being of a well defined and regular outline, and of a very rich deep purple, of a much deeper hue than any that has yet flowered. The petals and sepals, too, are well formed, and the delicacy of their colouring contrasts beautifully with that of the labellum. Yet another gem of greater beauty than the preceding attracts the eye. Close by, in the shape of a charming variety of *C. Trianae*, indeed it is supposed to be a natural hybrid between *Trianae* and *Warneri*, as it possesses the characteristic petals of the former with the labellum and throat of the latter. The labellum is large and well formed, and of an intense rich purple crimson colour, whilst the sepals and petals, which are unusually large, are of a delicate blush, faintly suffused with the rich colouring of the labellum. Another beautiful *Cattleya* we noted in flower—*C. delicata*, which, as its name implies, is of a soft pleasing colour, a great favourite with ladies.

A group of *Dendrobium Warianum* in flower was interesting, amongst which was a very superior type as regards size and depth of colour of flowers. The petals and sepals were considerably above the average in size, and in point of colour the tips were of a much deeper hue than is generally met with, as also was the colouring of the lip. Above the average, too, in depth of colour and size of petals, sepals, and lip, was a small plant of *Dendrobium crassinode Barberianum*. Several other interesting Orchids were in flower, such as *Lælia harpophylla*, the sweet-scented *Dendrochilum glumosum*, *Lycaste Skinneri*, *Sophronis grandiflora*, &c.

After our brief hurried inspection of the Orchids we had a glance through the other houses. Perhaps the most interesting sight of all was to see the houses devoted to raising seedling Begonias. Seated on high stools before a bench in one of these houses were several expert young men busily engaged in the difficult and tedious task of pricking off the

seedling Begonias from the seed pans into other pans. It requires an expert hand and sharp eye to separate and transplant the almost invisible minute little seedlings without injuring them in the process. Yet this is done with a very small percentage of losses. As affording an idea of the delicate nature of such a task, we may mention that in each pan of about 10 inches in diameter there are pricked out with mathematical precision from 200 to 300 tiny plants. The operator holds a fine-pointed stick as a dibber in one hand, and a similar sized stick with a small fork at the end in the other, with which to lift and separate the seedlings. Some hundreds of pans, representing hundreds of thousands of plants, besides an enormous quantity of last year's bulbs shows the gigantic trade carried on annually by this firm alone in Begonias. Caladiums, too, are a special feature here, several first-class varieties having been raised here. In another house we saw a large quantity of Azalea Deutche Perle in flower. This variety deserves to be grown more extensively than it is on account of the beautiful shape and colour (white) of its flowers, which resemble the buds of a well-grown Gardenia bloom.—T. W. S.

### CYRTOPODIUM PUNCTATUM VAR. SAINTLEGERIANUM

ALTHOUGH about twenty species of *Cyrtopodiums* have been discovered few have come into cultivation, and these are not by any means frequently seen in collections. Yet such species as *C. punctatum* are very handsome when in flower, and some of the yellow-flowered forms are also highly attractive and distinct from the majority of Orchids. Of the three or four species met with in gardens *C. Andersoni* is interesting, the flowers being bright yellow and borne in racemes or slightly branching panicles. It is a tropical American plant, and it is said "a paste or glue is prepared from its fleshy stems" that is there employed by shoemakers. *C. cardiochilum* is similar to this in the form and colour of the flowers, and is beautifully figured in Williams's "Orchid Album," vol. iv., t. 176.

*C. punctatum* has been long known as an effective Orchid, the large panicles of flowers being produced freely, of a yellow tinge spotted with red, the lip being much brighter than the sepals or petals. It was discovered by Plumier in Hispaniola, and mentioned as "*Helleborus ramossissimus cauliculis et floribus maculosis*." Mr. Wm. Swainson introduced it from Brazil, and it first flowered in the Glasgow Botanic Garden in 1835.

*Cyrtopodium Saintlegerianum* has been described by Reichenbach as a new species, but it seems to differ so little from *C. punctatum* that it would be better regarded as a variety of that species with more highly coloured flowers. Mr. B. S. Williams has given an illustration in the "Orchid Album" of *C. punctatum* which appears to be identical with the *C. Saintlegerianum* recently shown at South Kensington by A. H. Smee, Esq., The Grange, Wallington, and then awarded a first-class certificate. The plant was, however, collected and brought over in May, 1883, by M. de St. Leger from Paraguay along with *Oncidium Jonesianum* and *O'Brienianum*, and it is just possible that the plant from which the figure above referred to was taken was really the variety *Saintlegerianum*, which is superior in colouring to any form of *C. punctatum* we have previously seen. Our figure was prepared from flowers sent us by Mr. Smee and shows the general character well. The panicles arise with the young growths, and as the former are freely branched they are well adapted for cutting.

Mr. G. W. Cummins, the gardener at The Grange, forwards us the following cultural note in reference to this handsome Orchid:—"It is of easy culture if potted with good drainage in a compost of rich loam, peat, potsherds broken small, and treated occasionally with a supply of liquid manure during the growing season (Clay's fertiliser being used for the plant under notice at the rate of one teaspoonful dissolved in a gallon of water). Soon after commencing the use of the manure many fibres were noticed shooting upwards from the thick fleshy roots. The temperature which suits it best is that of a warm house where *Vandas* grow well. The graceful Palm-like appearance of the foliage renders the plant attractive even when not in flower."

### THE WEATHER AND VEGETATION.

#### ENGLAND AND WALES.

##### BUCKINGHAMSHIRE.

THE past winter will long be remembered, or more especially that part of it dating from January 3rd to March 18th, for during this period, except on two nights, we experienced severe frosts and almost sunless days, with a cold wind ranging from north to east. On January 6th 8 inches of snow fell, which remained on the ground sufficiently to protect vegetation a little until the middle of February, when a slight thaw set in for two days. Since that time we have had occasional snow-

storms, which disappeared with the first glimpse of sun. The continued cold easterly winds, accompanied by sharp frosty nights, killed about half our Broccoli and spring bedding plants; Wallflowers, *Myosotis*, Pansies, &c., are much cut up, although since the change to warmer and showery weather plants that previously appeared almost lifeless are starting into growth. Trees and shrubs generally have suffered but little, and we should have abundant fruit crops, buds now only just pushing. Birds are very troublesome here at all times, and necessitate netting Gooseberries to save the buds. The coldest nights of the winter were on December 10th, 17° of frost; 11th, 15°; January 6th, 20°; 7th, 22°; 8th, 16°; 9th, 15°; February 8th, 15°; 9th, 17°; March 6th, 16°; 16th, 15°. Total number of degrees of frost registered from January 1st to March 18th, 451, as against 266 for the corresponding time last year.—CHAS. HERRIN, *Chalfont Park Gardens, Gerrard's Cross*.

PEAS sown 23rd November on a south border have stood remarkably well. At present they are from 2 to 3 inches above ground, and are a good plant. The forwardest at present is William I. We did not sow American Wonder in autumn last year, as we found it too tender for autumn sowing. Coleworts and Brussels have stood well; autumn-planted Cabbage, Ellam's, about half are killed. All Cauliflower plants where not protected are killed. Of Lettuce, Bath Cos and Hick's Hardy, about half the plants killed. Savoy and Cottagers' Kale have stood very well. Broccoli, Cooling's Matchless, Veitch's Spring White and Self-protecting, very much injured. Dilcock's Bride and Webb's Perfection have stood well, and look healthy. Celery, where not protected, is very much injured. Double Violets mostly killed where not protected, such as Marie Louise, Neapolitan, and Swanley White. Single varieties are much injured, but will recover. The most frost we had here in one night was 18°. It seems to me that the continual low temperature for so many nights and days has caused much damage to vegetation.—J. SMITH, *Mentmore, Bucks*.

##### CORNWALL.

THE weather has been unusually cold, a long prevalence of east winds, especially in February and March. No snow and frost except on three or four mornings, January 8th being lowest—viz., 28°, or four degrees of frost. The plants generally are uninjured. Pelargoniums and all tender succulents have not suffered in any way. Pelargoniums and tender plants were destroyed in 1881, but nothing like it has occurred this winter. The Narcissus and Potato crops were quite three weeks later than usual this season.—GEO. D. VALLANCE, *Gardener, Tresco Abbey, Scilly Isles*.

##### DERBYSHIRE.

AT last we have the ground cleared of snow and a cessation from frost. What pleasure this gives can only be felt by those who have been snowed and frozen up since January 11th. The intense cold in March has only been equalled by that in January, 1880, during my location in Derbyshire. For twenty-six consecutive days and nights the thermometer never once rose above freezing point on a north wall, but varied between 4° and 31°. Vegetation in this neighbourhood is in a sorry plight, Brussels Sprouts and Broccoli being almost a mass of decayed matter, and the autumn-planted Cabbage less than when put in. The effects on the more tender of herbaceous plants I have not yet been able to discover; but I dread the worst, as the common Laurel and Yews show too plainly what they have had to brave.—WM. ELPHINSTONE, *Shipley Hall Gardens*.

##### DEVONSHIRE.

FOR the last six months the weather has been a continued change. After a dry summer September came in with a heavy rainfall; rain fell more or less for fifteen days. It had the effect of starting all shrubs and vegetables into active growth. October was very stormy, rain fell on fourteen days. November was very fine up to the 24th; in the next six days 3 inches of rain fell, the weather became much colder, and on December 9th we had 13° of frost; 10th, 10°; 11th, 17°; 12th, 11°; the remainder of the month was cold for this part of the country. January began with storms of rain and snow, and sharp frost followed on the 8th, 16°; again on the 21st, 18°, this is the lowest registered here, though 3 feet above ground, and snow covered the ground 2 inches in depth for seven or eight days. February was much finer, scarcely 1 inch of rain fell, and less frost was registered; 10° on the 22nd, again 10° on the 26th. March came in "like a lion," and continued so up till to-day, the 18th, the last fifteen days frost varying from 2° to 15°, with a keen east wind, which has completely dried up all the grass. The effects of all this has been most disastrous to Broccoli. Wilcove and Model are standing fairly well, Penzance and Veitch's Spring White were the finest last year, many heads weighing upwards of 12 lbs.; these are mostly killed this year. There is a paucity of Pear and Apple buds, and they will be very late. The young shoots of *Euonymus* are cut. *Eucalyptus* are all killed to the ground. *Fuchsias* are much cut, but the *Myrtle*, *Escallonia*, Japanese shrubs, and climbers are free from injury. In the borders many biennials have suffered; Sweet-scented *Aloysias* we grow in quantity on walls are unhurt. Stocks are all safe, but want warm weather to start them into growth. Everything is very late here. Thermometer 1 foot below the surface shows a temperature of 37°. Scarcely a Primrose to be found on the banks, or a Daffodil in the fields, of which there is usually abundance weeks before this time. I forgot to say *Veronicas* and *Coronillas* are very much injured with frost, but not killed. These gardens are rather exposed, and a great height above the sea. The villages near are very much warmer, being in the valley of the Yealmon river.—GEO. BAKER, *Membland Hall Gardens, Plympton*.

WE have experienced a very long and trying winter for the garden. Frost was registered for the first time on the 25th of September, being the earliest date on which it has occurred during the past twelve winters, being the limit of my experience of the Devonshire climate. Though it commenced thus early, having our tender vegetables and flowers destroyed, yet during the next two months frost was only registered on five occasions for each month, the minimum also for each being 5°. October was a rainy month, rendering the gathering and storing of fruits in such a dry condition as one would wish rather difficult. December was dull, frosty, and cold, nineteen nights having frost registered. The cold seems now to have set in, for January records show twenty-two, and February, twenty-four frosty nights. The first month of the year rain fell frequently

vegetable shed, from which place batches are taken as required to the forcing house. The same with Asparagus, it was taken up and heeled in where it was easy of access whenever required for forcing. Rhubarb covered outside has come on very slowly, so much so that we have been obliged to take up extra roots and place in the forcing house. Parsley roots only attained to a very small size last year, consequently that has been scarce.

Fruit trees have their buds well retarded, so much that we hope to escape the sharp frosts that frequently prevail when they are in bloom. Our Apricots, which were in full bloom on the 10th of March last year, the date on which our cloths were put up for protecting them, have only a few dozen blooms expanded at the time of writing. Peaches and Necta-

Fig. 46.—CYRTOPODIUM PUNCTATUM VAR. SAINTLEGERIANUM.

during the day, and with frosty nights, evergreens, such as are not perfectly hardy, suffered much, Camellias, some of the Hybrid Rhododendrons, Desfontanias were very much cut, while Veronicas were killed.

Green vegetables had become exceedingly scarce. Broccoli were very small, owing in great part to the preceding dry summer and autumn, and have been cut by May and used for greens, the chances being that only very small heads would have been formed. Borecole and Kale that had been topped before Christmas have scarcely broken again. Celery, where not protected during the cold of January and February, was destroyed. Brussels Sprouts have been seriously cut where exposed, but our own have yielded a continuous supply. Spinach made very little growth, but being perfectly hardy, has been valuable. Turnips have not yielded any greens, but the roots have remained in fine condition for use, Veitch's Red Globe being an excellent winter Turnip, in fact we grow it all the summer, for after it has thrown up its flower stems in summer it is excellent for table use; not so with most other varieties. Seakale roots are all taken up before Christmas and stacked in a dry state in the

rines cannot be out until April has advanced. Pears are swelling their buds since the mild and rainy weather has set in. Apples are very backward, indeed scarcely making a move, but together with Pears are well set with bloom buds, even though we had such an abundance last year. Plums and Cherries are equally backward, and are thickly studded with bloom buds. Gooseberries have been attacked by the bullfinches and sparrows much more than usual. These are just bursting their foliage. At present there is every prospect of another fruitful season. Planting operations have been much retarded where left till spring. Our fruit trees were all planted, and others lifted that required, some time before Christmas. The mulching of decayed manure placed around each being again mulched with long stable manure, and pegged down to prevent the birds from digging it out. This keeps the borders tidy, being as neat now as when put on four months ago, and will remain so during the coming spring and summer, providing also against drought.

The great change that has taken place will cause rapid strides to be made a few days only having brought out the Daffodils, Primroses, &c.,

and we shall soon be tempted to forget the experiences of the late bitter cold weather in the warm and sunshine of genial spring.—D. C. POWELL, *Powderham Castle Gardens*.

## ESSEX.

THE weather experienced has been generally cold and sunless here, about two miles north of the Thames, in a low and damp situation. The fogs have been heavy, no very severe frosts, but continuous until the 20th. The frost has not been out of the ground in the shade since the beginning of January: 17° of frost is the most registered. The absence of snow during February and March has had a bad effect. Shrubs are uninjured, but vegetables are destroyed, unless protected. Cabbage stumps killed, nine-tenths of the Savoy tribe also; Brussels Sprouts have held their own again, Lettuces nearly all gone, Spinach less than at Christmas, autumn-planted Cabbages nearly all perished.—J. GADD, *Belthus Gardens, Aveley*.

## LANCASHIRE.

ALTHOUGH the winter has been long and severe for this neighbourhood, vegetation generally has not suffered to any great extent. The most harm has been done to annuals and biennials, such as Candytuft, Antirrhinums, Campanulas, and similar plants. Carnations and Roses have suffered not so much from the severity of the weather as from the continual thaw during the day for the past month. Many of the former have been lifted out of the ground, and will therefore succumb. The latter, such as *Souvenir de la Malmaison* and *Tea* varieties, will have to be pruned hard back, they are all right at the base. Stocks, Wallflowers, Auriculas, and spring-flowering plants have suffered much from the same cause. Rabbits have done much mischief, having barked the fences, Apple trees, Hollies, &c., that they could get at, as well as cleared off Carnations, Pinks, and all plants of a similar nature. This has been the longest and most sunless winter experienced during the ten years I have been in this neighbourhood. We have on several different occasions registered more frost, for instance in 1882, when the thermometer fell below zero, and vegetation suffered more than has been the case this year. We have only registered 16° of frost here, which was on the morning of the 7th inst. February has generally been mild, and brought fruit trees into blossom early only to be destroyed by late frosts. Everything is fully one month behind, and I think we may look forward for a good fruit year.—W. BARDNEY, *Norris Green Gardens, West Derby, Liverpool*.

## LEICESTERSHIRE.

THE coldest nights we have had this winter were—September 26th, 26°; 27th, 27°; 28th, 26° Fahr. November 16th, 17°; 17th, 23°. December 8th, 17°; 11th, 13°; 33rd, 20°. Feb. 24th, 19°. March 4th, 16°; 5th, 17°; 7th, 9°; 8th, 15°; 9th, 21°; 10th, 16°; 11th, 19°. These were the lowest readings of the thermometer. Probably the frosts of September did more damage than all the rest during winter, and will most likely be remembered for many years to come by gardeners, nurserymen, and florists, most of whom must have suffered seriously; some of the latter in this district (who are not in a very large way) have estimated their losses at upwards of £50 each. Their principal damage, I think, would be in *Chrysanthemums*, which were a general failure. *Azaleas* suffered a great deal, the bloom buds falling off as soon as they were put into the forcing house. The principal injury during the winter has been to vegetables; Broccoli and Cabbage have suffered very much. I have never seen spring Cabbage cut up so before. Vegetables have been very scarce about here, principally owing to the ungenial weather in the summer and autumn. For several days the thermometer ranged from 70° to 80° during the day in the shade; at the same time the night temperature would range from 34° to 40°, and many vegetables did not grow large enough to cut; this is one cause of scarcity, and scarcely any growth was made after the sharp frosts in September. As far as I can judge at present very little damage has been done to shrubs and Coniferae. An unusual quantity of snow has fallen this winter, and the ground in many places was covered from Feb. 20th until March 18th, when a change to milder weather set in, which I hope will continue.—J. L. B.

## LINCOLNSHIRE.

THE weather has been very severe in this district for the past nine weeks. Snow fell on January 8th, and in all ten days snow fell; sharp frost on the 20th, 14°; temperature very low all the month. In February snow fell on five days, sharp frost on twenty-six days, greatest on the 7th, 14°; temperature very low all the month. March, heavy fall of snow on the 1st, 6 inches; very sharp frost on the 8th, 22°. From the 1st of January to the 18th March we have only had five nights without frost, and the ground has been covered with snow more or less from the 8th January to the 18th March, when we have had a change. Broccoli, Brussels Sprouts, Greens of all kinds are very much injured—in some cases past recovery. Portugal and common Laurels, Aucubas, *Laurustinus*, and *Arbutus* much injured. I am afraid Apricot buds are much injured, but must wait till the buds unfold to see the full extent of damage done. Garden operations are far behind. Turnips have decayed on the ground through the severe frosts.—DAVID LUMSDEN, *The Gardens, Blowholm Hall, Lincoln*.

## MONMOUTHSHIRE.

THE winter of 1885-86 will be remembered by horticulturists on account of its severity and the consequent results—injury to vegetation and heavy coal bills. Fortunately many plants have been partially protected by snow from the most intense frosts; but here the snow itself wrought considerable damage amongst trees and shrubs. In the first storm it fell so suddenly and densely, and being unaccompanied by wind it laid heavily

on the branches, and many were broken down by its weight. Amongst Coniferae, tall specimens of Junipers and *Cryptomeria japonica* suffered most, and before they could be relieved from their burden—and many deciduous trees, especially Acacias, Elms, and Oaks—have lost large branches.

In the vegetable garden the crops belonging to the Brassica family are much damaged, the Broccoli particularly so. Quite three-fourths of them are killed, while the other are crippled. Winter Spinach is shrivelled, and Endive, Parsley, and Celery where unprotected was greatly injured. The greatest depth of snow we experienced was 9 inches, and the most severe frost 26°. There is an old adage, "It's an ill wind that blows no good." Some good we may hope to derive from the protracted inclement weather—viz., late blossoming of fruit trees, and their escape from spring frosts.—THOMAS COOMBER, *Hendre Gardens, Monmouth*.

## NORTHUMBERLAND.

MARCH, 1886, will be long remembered in Northumberland as one of the severest on record. On the 1st, 2nd, and 3rd snow fell continuously, and drifted into immense thickness, from 5 to 15 feet, blocking all traffic on roads and railways, and in this part of Northumberland people had to be content without their letters and newspapers for four days. Such a thing has not occurred since this line of railway was made nearly forty years ago. In looking over the old registers of the weather, I find the thermometer has only on two occasions been so low in March since the year 1841. From that year to 1867, the mean temperature for March was 40°. On March 17th, 1867, there was 14°, and from that year to 1881 the mean temperature was 37°. On the 1st and 2nd of March, 16° and 15° consecutively, and on the 6th, 9th, and 13th of the present month we had 13°, 13°, and 12°; and from 1881 to the present month I find the mean temperature still declining to as low as 34°, which bears out Mr. Thomson's remarks in his letter to the *Scotsman*, and also in his excellent little book, that our climate is deteriorating. And in looking back fifty years in our old meteorological register I find such observations as "Fine day; warm; genial growing weather;" but now our summers are much colder, and we have now, as a rule, to write, "Dull cold day throughout," or "Hazy day, with cold east wind."

We have not been able to get any seeds in the ground yet, as we have had no good weather since Christmas, and shall not be able to do so all this month, let the weather be ever so favourable. Our early Cabbage have stood well, and come out fresh from under their deep covering of snow. Hardy fruit is now on the move. Apricots are showing some flowers, and should we have no frosts later on we expect as good a crop as last year.—D. INGLIS, *Howick Hall Gardens*.

## SUSSEX.

AT last, on March 19th, we had an agreeable change of weather. This was the first day the soil had been in a fit state to receive any kind of small seeds, it having almost continually frozen since the new year. Of the seventy-seven days up to the 18th of March the thermometer fell below the freezing point on fifty-eight nights. There has been no extreme frost. The lowest readings were—January 8th, 19°; February 8th, 9th, and 10th, 22°; March 7th and 17th, 20°. The eighteen days of March have certainly been remarkably severe, only on the night of the 2nd it did not freeze; and the readings for the eighteen days give an average minimum temperature of 25½°. The snow that fell on the 1st March was all gone except where drifted the next day, so that vegetation has suffered from the effect of the frost very much. Lettuce and Parsley have vanished; the edges of Cabbage and Broccoli leaves are withered as if scorched. Buda Kale is about the only thing that has not suffered. Many vegetables, such as autumn-sown Onions and Cabbage in the seed beds, are thrown out of the soil and are withering on the top; and even large labels in the kitchen garden have been gradually worked up till they have tumbled over, where they were firmly inserted in the autumn.—R. INGLIS, *Cuckfield, Sussex*.

## WARWICKSHIRE.

WE have had a long cold winter with dark sunless days and heavy falls of snow, but not very severe frost, the most we registered being 18° on the 6th of March. No damage has been done to shrubs. Vegetables, such as Broccoli, winter Cabbages, &c., have suffered most, which is always the case with such frosts as we had in the beginning of this month with bright sunny days. Vegetables are very scarce in this district. We had a dry summer with little rainfall until the second week in August; then the weather broke up with a hailstorm such as has not been witnessed here since 1851. Wheat and Oats were nearly destroyed. I have charge of a farm here in conjunction with garden and estate work. I threshed 20 acres of grand straw crop of Oats, and they did not produce two quarters per acre. I enclose a leaf of Aucuba to show the effect the hail had on them, and everything in the shape of green vegetables were destroyed. A pond in the kitchen garden containing Water Lilies had the appearance of a huge bowl of fine "mint sauce."—WILLIAM BROWN, *Solihull*.

## WESTMORELAND.

SUDDEN changes in the weather have been experienced this long winter, which began, I may say, on September 26th, when 6° were registered. March came in with exceptional severity, and has continued more or less to this date; 22° of frost on the 7th inst. is the lowest temperature recorded this winter. The fierce north-east winds at the beginning of this month soon played sad havoc amongst the green stuff; Cabbage and other plants have disappeared. The Broccolis were laid as usual in November, and the winter ones are useless. Dilcock's Brie, Leamington, and Lauder's Goshen amongst the spring ones, seem uninjured as yet.

Brussels Sprouts are black and withered, and Chou de Burghley unrecognisable.

Amongst shrubs, Portugal Laurels and Berberis Darwini already show the effects of the storms. There has been very little sunshine, which accounts for the slow progress in the forcing department. As it is no use lamenting, we have got all available materials made up into hotbeds, and Cauliflowers, Lettuces, Brussels Sprouts, &c., are coming on to make up for losses as soon as possible. Autumn-sown Cauliflowers are potted and in comfortable quarters, although those in hotbeds invariably come in use before them.—W. A. MILLER, *Underby Gardens, Westmoreland.*

#### WILTSHIRE.

THERE has not been such a prolonged period of frost in West Wilts for several years. In this neighbourhood the green garden crops have suffered severely, especially the Brassicas, which look as if scorched with fire. This in our case has been more the result of continuous and bitterly cold east winds than low temperature registered, for the lowest reading, 10°, = 22° of frost, was registered March 8th.—ALEX. MILLER, *Road Ashton Park, Trowbridge.*

#### SCOTLAND.

##### BANFFSHIRE.

THE winter here has on the whole not been remarkable for its great severity, either as regards a very low temperature or great snowfall; but notable for its very low temperature through nearly the whole of February and up to the present date, March 17th. Frosty nights with frequent showers of snow have been the most prevalent during the last six or seven weeks, snow often melting in exposed places through the day. Four to five inches deep on two occasions is the most we have had through the winter, and roads have not been drifted to interrupt communication. Winter commenced here early. We began filling the icehouse on the 18th November, an unusually early period. December was a mild month and the year began mild. The temperature in the shade on January 1st was 56°. The weather continued moderately fine until the middle of the month, when frost set in. On the 19th the mercury fell to 15°, or 17° of frost. This, and 16° on the 12th of March, are the lowest registered here. Vegetation is very much retarded, but hardy plants have shown no signs of being injured in this locality. Some Apricot blossom opened on a south wall under protection on the 12th inst. was injured by the frost above mentioned.—JOHN WEBSTER, *Gordon Castle Gardens.*

##### BUTESHIRE.

THE weather here has been both a long and a severe one for our west coast. The frost here is never very severe; for November our lowest reading was on the 14th, 24°; and for December the lowest was on the 5th, 19°; and for January the lowest was on the 6th, 20°; and for February the lowest was on the 4th, 21°; and on the 6th of this present month our readings were 20°, or 12°. We have had a continuance of snowstorms since the 4th of January, but we had no damage done to shrubs, as they are all kept trimmed; but many that stood former winters in our kitchen garden have been killed this winter, such as autumn-sown Onions, Cabbages, Savoys, Lettuces, and some other seedlings that stood in former winters without protection.—DAVID MCAUSLIN, *Castle Gardens, Brodick, Isle of Arran, Buteshire.*

##### DUMFRIESHIRE.

IN November there was frost on fourteen nights, giving a total of frost of 100°, the most severe being on the morning of the 18th, when the thermometer stood at 12°, or 20° below freezing. This month was characterised by sudden changes from frost to thaw. December.—There was frost on sixteen nights with a total of 154°, the most severe being on the 11th, when 20° of frost were registered. This month was also remarkable for the number of times it changed from frost to thaw. January.—There were twenty-five nights of frost, with a total of 248°. On the 17th, 18th, 19th, and 20th there were respectively 27°, 27°, 28°, and 26° of frost. February.—There were twenty-four nights of frost with a total of 199°. There was a good deal of snow, lying nearly the whole month. March.—It has been frosty every night up to date, the sixteen nights giving 160°. On the 7th and 12th there were 25° and 21° of frost respectively. The 1st and 2nd gave such a continuous snowstorm as has rarely been seen by anyone. Vegetables stood well all through February, but since the snow has gone this month almost every green leaf except Leeks have disappeared.—DAVID THOMSON, *Drumlanrig Gardens.*

##### MIDLOTHIAN.

THE rather severe and protracted winter has scarcely left us yet, and it is not safe to estimate the amount of injury done by it to vegetation before we see the effects of warmth and bright sunshine on weakened plant life. Up to the end of 1885 the weather was very much of a normal character, but with the advent of the new year the temperature began to fall below the average and has remained so till this date. The minimum was reached on the 19th and 20th January, when the thermometer registered 10°, or 22° of frost; and the maximum on January 1st and to-day (20th March), the thermometer rising to 52° in the shade. From the 1st to the 18th of March more or less frost has been registered every night, the severest being 18° of frost on the morning of the 7th. Snow fell heavily on the 1st and 2nd of March, which in many places helped to protect vegetation from the severity of the frost, although in open places the strong gale of the 2nd swept it clear off and left vegetation fully exposed to the cold. In such places vegetation has suffered much from the daily freezing and thawing, as well as from the keenness of the blast. The snow

still lies deep in many places, especially in the upper parts of the county, and it will be some time before the heaviest of the wreaths formed by the gales of the 2nd and 16th melt clear away.

So far as can yet be seen trees and shrubs have suffered comparatively little. Where exposed to the full sweep of the frosty gales evergreens have had their foliage browned, and probably will lose a portion of it prematurely, but otherwise there is no sign of any permanent injury, such as we have seen after the severe winters of recent years. Fruit trees are perfectly safe, as, owing to the continued low temperature, they have remained dormant up to the last day or two. They are generally full of flower buds, and with a genial spring promise an abundant crop. Vegetables, especially where exposed to the blast and on heavy damp soils, have been a good deal cut up, but on warm and dry soils they have stood fairly well, and where protected by the snow even Broccoli is fresh and good. Brussels Sprouts and Borecole have of course formed the staple "greens" for the last month, Cabbage and Savoys having in most places melted away with the continued freezing and thawing, almost of daily occurrence through December and January. Autumn-sown plants of Cabbage, Cauliflower, &c., have suffered greatly, and there will be a great scarcity of them in some parts for early spring planting. At present the season is about three weeks later than the average, but the soil is in excellent condition to receive the crops, and with favourable spring weather the lost time would soon be recovered.—M.

THIS winter has been long and severe, and remarkably changeable. Its effects on vegetation no doubt have been severe, the ground here being coated with snow to the depth of 18 inches for the last month. The frost we have had this month has been very severe, and would have thrown herbaceous and other spring-flowering plants out of the ground, but luckily the covering of snow we have had so long has been a great protection. March has been one of the worst for snow and frost that has been experienced by the oldest people in this district. We are three weeks or a month later this season from last. From the 1st of December, 1885, to March 16th, 1886, rain fell on twenty-three days, amount 3 inches; snow fell on eighteen days; sunshine fifty-five days more or less; frost fifty-eight days. Total amount of frost 417°.—J. W. MACHATTIE, *Newbattle Abbey Gardens, Dalkeith.*

##### PERTSHIRE.

NOT since 1881 have we experienced such a severe winter in this district; we had then the frost much more severe on several nights, but this winter has been much more protracted, as since 5th January to date (20th March) with the exception of a few days in February, the ground has been covered with snow to a depth of several inches, and there are few nights that frost has not been registered, the severest frost occurring on the 19th January, when the glass went down to zero. Fruit trees and shrubs are apparently uninjured; vegetables, however, have suffered severely, and vegetation is far behind.—JAMES BROWN, *Abercainey Gardens, Crieff.*

##### SELKIRKSHIRE.

THE week ending March 13th will be remembered for the amount of frost which was recorded; we had 115° in the week. Nature, when released from the bonds of frost and snow, may be expected to advance by leaps and bounds, and certainly she must do so to make up for lost time. Seed time, we are told, will surely come—certain it will be a late one. We are apt to think present time afflictions and annoyances the worst ever experienced, and we may sometimes be wrong when we abuse the weather as the "worst we ever knew;" but we may be pardoned for thinking that this March has certainly proved extremely severe and trying.—SCOTIA.

##### WEST LOTHIAN.

THE weather here up to January 3rd was seasonable. Since then to about the middle of February it was very severe, with frost and snow stopping all ground work. After a break of a week to ten days of mild weather, it again came in with the 1st of March very severely from the east, with wind and blinding snow, which continued more or less until the 19th, when a change to spring weather came and still continues. 23rd March—Peaches, Apricots, Pears, Gooseberries are swelling their flower buds. The two former will soon be in flower if the change continues. Shrubs, Portugal Laurels especially, are scorched in exposed places as if they had been burned. Roses are as yet dormant, but may grow from the root and the old wood. Aucubas have fared the same as Laurels; perhaps the sea may account for the scorching, as we are within three minutes walk from the shore.—JOHN MOYES, *Dalmeny Park, Edinburgh.*

##### IRELAND.

FOR the past twelve years here we have had more severe seasons for the time being, but not so protracted. Our first severe frost was in first week of December, lowest temperature 15° of frost; next, second week in January, lowest temperature 13°, on 7th. Fourth week we had a very sharp week, lowest temperature 18° of frost on 22nd. Our most severe frost in February was on the 26th, 10° of frost. This month has been one of the most severe I remember, ushered in by a heavy fall of snow, making roads impassable where it drifted. Where the sun did not reach, it is still lying. Ground was again covered with snow on the 16th and 17th first week of this month. Our sharpest frost was on the 4th, 14° of frost, the same in the preceding week. Since then 10° has been the most severe. Vegetation seems to have suffered less than in previous years. I was dubious about our advanced Pear buds, but they seem to be safe.—WILLIAM LEES, *Gardens, Hillsborough Castle, Co. Down.*

## HORTICULTURAL SHOWS.

BATH.—MARCH 24TH AND 25TH.

ALTHOUGH only a comparatively limited number of competitors entered for the various good prizes offered, the second annual Exhibition must be classed as a decided success.

**Bulbs.**—There were four exhibitors of eighteen Hyacinths. Mr. S. P. Budd (W. Taylor, gardener) leading with fine massive spikes of the leading varieties. Messrs. G. Cooling & Son, Bath, were awarded the second prize for a very creditable collection; and Mr. J. Cypher, Cheltenham, took the third prize. With twelve Hyacinths in six pairs, Messrs. Cooling & Son were first. Mr. Budd was first in two other classes for Hyacinths, and Messrs. Cooling & Son second. While in a class for twelve varieties Mr. S. Tredwell (J. Durbin, gardener) took the lead; and Mr. Budd was second. With six varieties Mr. T. Jolly (A. Hawkins, gardener), and Mr. Budd were awarded equal firsts, and Mr. C. H. Dutton an extra prize. Messrs. Cooling had the best twelve pots of Tulips. Mr. Budd was a good second; a certificate of merit being awarded to Mr. C. H. Dutton. Messrs. Budd and Dutton were also successful in the other classes for Tulips. But few Polyanthus-Narcissi were shown. Messrs. Cooling had the best display of Daffodils, and these including some of the best varieties. There were some good Amaryllis shown by Mr. Tredwell, the second prize going to Mr. T. Jolly.

**Flowering and Fine foliage Plants.**—Three classes were provided for Orchids, and these were a very attractive feature in the Show. Mr. J. Cypher had the best six, consisting of *Lycaste Skinneri*, bearing ten fine blooms; *Cattleya Triana rosea*, eight good blooms; *Cattleya amethystiflora* with three handsome spikes; a fine pot of *Dendrobium nobile*; *Cattleya Triana* with five fine blooms, and *Cypripedium Lowi* with three strong flowerstems. Mr. E. E. Bryant (W. J. Mould, gardener) was second for neat plants; Messrs. Cooling were first with three Orchids, and Mr. R. B. Cater second, the exhibits being very creditable in each instance; Mr. Cypher was also first for a single specimen Orchid, showing a strong plant of *Cypripedium villosum* with twenty-two fine blooms. Roses in pots were well shown by Mr. Budd and Messrs. Cooling, who took the prizes in the order named, the best plants being *Madame Villermoz*, *Madame Thérèse Levet*, *Violette Bouyer*, *Madame Lambard*, *Rubens*, *Catherine Mermet*, *La France*, *Niphetos*, and *Marie Guillot*. Mr. Bryant had the best four specimen flowering plants, and Mr. Cater was second, included among the latter being a grand example of a seedling *Amaryllis*, bearing eleven strong flower spikes; Mr. Bryant was also most successful with specimen *Indian Azaleas*. Only two specimen fine-foliaged plants were shown, but these comprised several noble Palms, notably *Cycas revoluta*, *Kentia canterburyana*, *Latania rubra*, and *Latania borbonica*; Mr. Bryant and Mr. W. C. Drummond second. The best miscellaneous group of plants was arranged by the Messrs. Cooling, Orchids, Roses, Arns, Azaleas, Ferns, and Palms being effectively grouped; Mr. Drummond was second. For a smaller group Mr. E. E. Bryant was first, the central plant of *Dracæna Lindenii* showing to advantage among numerous Palms, Orchids, and other choice plants. Three very pretty baskets of plants were shown, the first prize going to Mr. Tredwell, and Mr. R. B. Cater was a very good second, several Orchids being employed by the latter, while Mr. Tredwell made a bright centre of *Amaryllis*, *Narcissi*, *Gloxinias*, and *Azaleas*, a fringe of pot plants of double Violets giving a good finish to the basket. Messrs. Cooling had grand pots of *Lily of the Valley*, and was awarded the first prize, Mr. Budd taking the second. Mr. Tredwell was first for a very pretty collection of herbaceous plants in pots, and Messrs. Cooling second, and these exhibitors occupied similar positions with collections of Violets.

**Cut Flowers.**—The vases were not particularly good. Mr. E. Thomas was first and Mr. W. Dobson second. The prizewinning bouquets were very large and heavy. Mr. E. S. Cole was first and Mr. Winstone second, both coming from Bristol. Orchids, Roses, and *Lily of the Valley* were principally used. Mr. Cole was also first with a spray for a lady's dress, and Mr. W. Dobson second. Four good lots of cut Roses were shown. Mr. Budd was easily first, having fine bright blooms of *Rubens*, *Catherine Mermet*, *Souvenir d'un Ami*, *Duke of Wellington*, *W. F. Bennett*, *Alba rosea*, and *Madame Victor Verdier*. Mr. J. Chaffin was second with rather too fully blown Teas in variety, and Messrs. Cooling were third with a bright fresh collection.

**Fruit and Vegetables.**—Mr. W. Duck (J. Chedzey, gardener) took the first prize for two bunches of Grapes, fairly well kept *Lady Downe's* and *Black Alicante*, and an extra prize was awarded to Mr. W. Iggulden for a well coloured dish of Strawberry Princess *Frederic William*. Mr. R. Hooper Taylor was first for a dish of Pears, and Mr. J. Smith second, both having *Beurré Rance* in good condition. The best dish of Apples—*Reinette de Canada*—was staged by Mr. E. Thomas, the second prize going to Mr. A. T. Hall for a well kept dish of *Ribston Pippin*. The first-prize bunch of *Seakale*, shown by Mr. W. Smith, was very large, and Mr. T. Evry was a good second. Mr. E. Thomas was first for *Asparagus*, and Colonel Grant (G. Snow, gardener) second.

**Not for Competition.**—Twelve *Cyclamen persicum* shown by the Rev. E. Handley were remarkably fine, there being as many as eighty large blooms on a plant, and were generally considered the best ever seen in Bath. Messrs. Cutbush of Highgate, London, also had a considerable number of well-grown *Cyclamens* in their group of miscellaneous flowering plants and bulbs. Mr. J. Cypher, Cheltenham, arranged a fine group of plants, including several *Kentias* and other serviceable Palms, as well as various Ferns and fine-foliaged plants, among which were interspersed a great variety of good Orchids. The most noteworthy of these were *Cattleya Triana* in variety, *Lycaste Skinneri*, *Odontoglossum Rossi majus*, *O. Alexandræ*, *O. Halli exantoglossum*, *Dendrobium Wardianum*, *D. crassinode*, *D. luteoflorum*, *Cymbidium eburneum*, *Cypripedium Argus*, *C. biflorum*, *C. Boxallii*, *Cattleya citrina*, and *C. labiata* and *C. Percivalliana*.

CRYSTAL PALACE.—MARCH 26TH AND 27TH.

THOUGH competition was not so keen as usual, a bright little exhibition was provided at Sydenham on Friday and Saturday last, which attracted a number of visitors. Mr. W. G. Head made the most of the plants at his command, and arranged them in the centre transept near the large stage,

numerous contributions from the Company's houses assisting materially in improving the display. When the Palace was lighted at night with some hundreds of coloured lamps the effect was extremely beautiful.

Bulbs constituted the chief portion of the exhibits, the leading prizes being taken by Mr. H. R. Wright, Lee, and Messrs. H. Williams & Son, Finchley, amongst the nurserymen; corresponding prizes in the amateur classes being gained by Mr. T. N. Penfold, gardener to the Rev. Canon Bridges, Beddington House, Beddington; Mr. John Horsley, 6, Selwood Place, South Kensington, and Mr. A. Luff, gardener to R. R. Hyatt, Esq., Heatherset, Leigham Court Road, Streatham. The Hyacinths were generally the best, especially those from the trade growers, but they do not seem quite up to the standard of past years, and Tulips are not nearly so satisfactory. The *Lilies of the Valley* from Finchley were extremely well grown, with fine spikes of bells, and very seldom are they seen in such good condition. *Cyclamens* were contributed by the St. George's Nursery Company and W. Clay, Esq., Kingston, as well grown and flowering as freely as we are accustomed to seeing them from these well-known growers. *Mignonette* was not very extensively shown, but Mr. Luff had nine fine examples of tree *Mignonette*, large healthy plants flowering profusely, amply meriting the premier prize awarded for them.

A handsome group of stove and greenhouse plants was staged by Messrs. J. Laing & Co., who were awarded the first prize in the class. A choice collection of Palms, Ferns, and Azaleas, with Orchids, chiefly *Dendrobiums* noble and *Wardianum*, was shown, and being effectively arranged in a prominent corner position, the group was a valuable addition to the exhibition. Mr. H. James, Lower Norwood, who was placed second, had an elegant varied group of *Lachenalias*, *Cinerarias*, Azaleas, Orchids, &c., margined with *Isoplepis*. The miscellaneous exhibits for which special prizes were awarded were as follows:—Groups of *Cyclamens* from W. Clay, Esq., and the St. George's Nursery Company; groups of Hyacinths from Mr. H. R. Wright; collections of Daffodils and other flowers from Messrs. Barr & Son, Covent Garden, and Mr. T. S. Ware, Tottenham; *Cyclamens* from Messrs. Cannell and Sons, Swanley; Roses in pots from Messrs. Paul & Son, Chesham; and fine-foliage plants from Mr. F. Bause, South Norwood.

First-class certificates were awarded to Messrs. J. Laing & Co., Forest Hill, for *Imantophyllum robustum* Mrs. Laing, *Cattleya Lawrenceana* and *Begonia Gloire de Sceaux*, which have been previously described.

## GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

THE annual Spring and Hyacinth Show of this Society was held in St. Andrew's Hall on Wednesday, 24th March. The protracted severity of the weather made it a source of great anxiety to those interested in the success of the Exhibition, but fortunately a favourable change occurred a few days before the Show. The exhibits were equal in merit to those of former years, in some instances superior. The Hall was bright with flowers, and would have been improved in appearance had some large specimen foliage plants been arranged throughout. This is a want that has been felt in Glasgow shows for a number of years, exhibitors contenting themselves with sending their easiest-handled plants, which have even a smaller appearance in so large a hall. The decoration of the platform was admirably done by Messrs. Austin & McAslan, who staged hundreds of such spring plants as *Rhododendrons*, Azaleas, and Lilacs, and some very highly coloured Ghent Azaleas, much admired. Messrs. Smith & Simons had a large collection of plants of the same kind, which were remarkable for the vigour and size of the flowers. Mr. John Sutherland, Lenzie, contributed a collection of choice plants, including a large number of seedling Azaleas of more than average merit, were highly commended. Messrs. Dobbie & Co., Rothesay, had on exhibition six extraordinary large Pansies, very highly commended. Mr. Peter McKenzie had six magnificent bouquets of choice flowers; one large bouquet of Roses, and one of white Camellias and *Lily of the Valley* were specially fine and highly commended by the Judges.

In the nurserymen's class for best collection of bulbous plants in flower Mr. Peter McKenzie, Paisley, was first with a splendid group; Mr. Sutherland, Lenzie, a good second. In the class for twelve plants for table decoration Mr. Sutherland had first prize with very uniform plants. He also had first prize for a hand bouquet of white Camellias and choice Orchids artistically arranged. In the class for eighteen Hyacinths, distinct varieties, Mr. P. McKenzie was again successful in securing first place with magnificently grown and well-finished specimens of the following varieties—viz., *Mimosa*, *La Grandesse*, *Howard*, *Czar Peter*, *Alba superbissima*, *Gigantea*, *Charles Dickens*, *Ida*, *Koh-i-noor*, *Vuurbaak*, *Lord Derby*, *General Cavaignac*, *King of the Blues*, *Mont Blanc*, and *Le Prophète*. Mr. Sutherland had second and Mr. Lister, Rothesay, third prizes. In the gardeners' and amateurs' classes for pot plants, Mr. Thomas Hogg, gardener to John Gordon, Esq., Aitkenhead, was the most successful competitor, a position he has maintained for many years. In the class for six stove and greenhouse plants he had first prize; specially noticeable were his *Rhododendron* Countess of Haddington, *Imantophyllum miniatum*, and *Dendrobium nobile*. He was also first in the following classes—three specimen Azaleas varieties, three Azaleas varieties in 8-inch pots, three *Amaryllis*, three Orchids, two *Gleichenias*, six *Cyclamens*; and in cut flowers first for six trusses hardy *Rhododendrons*, and six blooms Camellias. Mr. James Clotworthy, gardener to R. Ramsey, Esq., Langside House, had first prize for three stove or greenhouse plants, *Rhododendron* Countess of Haddington being his best plant. He was also first in the following classes—viz., three hardy *Rhododendrons*, two *Euphrasias*, and a specimen *Deutzia*; he was also awarded a special prize for a table of plants 12 feet by 6, *Crotons*, *Dracænas*, and Azaleas being very good. Mr. Mathieson, gardener to J. L. Henderson, Esq., Westbank, Partick, had the first prize for the best collection of plants to fill a table 12 feet by 6, a very fine specimen of *Dæmonorops palambanicus* being conspicuous in his collection. Greenhouse *Rhododendrons* and *Cinerarias* were admirably shown by Mr. Hutchison, gardener to J. B. Greenshields, Esq., Kerse, Lesmahagow, and Chinese Primulas by Mr. Gray, gardener to Rev. W. Turnbull, Lesmahagow. Mr. McLachlan, gardener to Alex. Hutchison, Esq., Langside, was first for Azalea *amena*, a very large specimen. In the class for twelve Hyacinths, distinct varieties, Mr. George Irvine, gardener to Mrs. Townsend, Pollokshields, was deservedly first, he also gained the first for six Hyacinths. Mr. H. Miller, gardener to William McOnie, Esq., Everslie, Pollokshields, had first place; he also had first prize in the following classes—viz., the most meritorious basket of spring flowers, six pots hardy

spring flowers, and four pots Crocus. The best Tulips came from Mr. Heron, Pollok Gardens, Pollokshaws, and Mr. Miller, Everslie. Mr. J. Mathieson had the best Narcissus. Mr. Heron and Mr. William Cowan, gardener to Captain Dick, Campbelltown, had first prizes for Lily of the Valley in pots not exceeding 12 inches and 6 inches respectively. Mr. George Meston, gardener to Morris Carswell, Esq., Pollokshields, had the best *Spiræa japonica*. For collection of vegetables in eight varieties, Mr. James Heron was first, Mr. Thomas Hogg second, and third Mr. John McLean, Auchanames, West Kilbride.

Very much of the success of the Exhibition is due to the untiring energy and zeal of the Secretary, Mr. F. Gibb Dougall, and Mr. C. McDonald Williamson, Treasurer, who do everything in their power to promote the interests of the Society.—G. R.

#### WESTMINSTER AQUARIUM—MARCH 30TH AND 31ST.

THE first of the series of exhibitions announced to be held this season in the Westminster Aquarium was opened on Tuesday last. Liberal prizes were offered in thirteen classes, the total amount being nearly £100. The competition was good in the principal classes, and the display was one of the most extensive and varied that has been provided in London this season. Many of the collections of bulbs had, however, been exhibited on several occasions before, and were somewhat the worse for their journeys. The Hyacinths also, as remarked in reports of these shows, were not so fine as usual, but the Daffodils, Lilies of the Valley, and market plants formed fresh and beautiful groups. At shows of this character it would be wise to make the market plants a stronger feature, and by that means some highly effective displays might be obtained. An attractive programme has, however, been announced under the superintendence of Mr. R. Dean, the Rose Show and Strawberry Fête being two of the principal events.

At the spring Show Mr. H. R. Wright, Lee, and Messrs. H. Williams, Finchley, secured the chief prizes for bulbs, such as we have already repeatedly noted. They were also the prizetakers with groups of market plants, both staging very diversified collections. The Cyclamens were excellent, especially those from the St. George's Nursery Company, and W. Clay, Esq., Kingston. The best Cinerarias were from Messrs. J. Carter & Co., Holborn, who were awarded the first prize for fifty plants. Pretty collections of hardy plants were contributed by Mr. T. S. Ware and Mr. R. Dean, who were placed first and second respectively. Three large groups of Daffodils were arranged by Messrs. Barr & Son, T. S. Ware, and Collins Bros. & Gabriel, which occasioned the Judges some difficulty in making their awards, but ultimately the first prize was adjudged to Messrs. Collins for an exceedingly choice collection.

The non-competing exhibits comprised two stands of brilliant Zonal Pelargoniums from Messrs. H. Cannell & Sons, Swanley, including flowers of some grand varieties. Cyclamens were contributed by the St. George's Nursery Company and Mr. Clay, a stand of the Pelargonium *Volonté Nationale* being shown by Mr. Perkins, Leamington. Special prizes were awarded to all these exhibitors.

#### SOIL—MOISTURE AND VEGETATION.

A SOIL is made up of solid particles of different sizes, ranging from pebbles down to the finest dust; being irregular in shape the particles do not anywhere fit close together, like sardines in a box. Of course, however, all of them must touch one another in many places, so that those above are supported upon those below, and those below cannot get from under their burden because hedged in closely on all sides by their next neighbours. There are spaces around these particles of solid matter, between the many points where they touch one another, which also vary much in size from such as are no wider than the thickness of goldleaf to such as are large enough to thrust one's finger into. These spaces are occupied by air or water, sometimes by one and sometimes by the other. If always filled with water, the soil is no better than a bog; if always filled with air, it is only a barren desert. Water that falls on the surface of the soil and can find its way from one to another of the larger spaces will run down till it reaches the level of the standing water in the ground; just as water poured into a pipe in a well does not stop till it reaches the level of the standing water in the well. But water that gets into the smaller spaces may be held there, many feet above the level of the standing water; as if, having filled the upper part of a well with sponges, we should then pour water in, we know that much of it, being taken up in the very fine capillary tubes of the sponges, will never reach the bottom; it will stay in them till it dries out by evaporation into the air.

The best condition of the soil is thought, by those who have studied its relations to water and vegetation, to be that in which not only all the spaces too large to hold the water up contain nothing but air, but where a large part of the small spaces are also empty. Our upland crops do not thrive in soils so situated that all these smaller spaces near the surface are full of water. Vegetation is constantly taking up this small residue of water that is left in the soil after the surplus of rain has drained off and dissipating it into the atmosphere; and when the supply of water is not sufficient to meet this demand at least to a reasonable extent, the plant wilts, or, as in the case of Indian Corn, its leaves curl up. How the supply is replenished when the rains are few and far between is a somewhat puzzling question. Too much credit is given to the power that the soil is supposed to have of absorbing moisture from the atmosphere; the amount so absorbed is of small account except when the air is very damp, which is not its usual condition at such time when rain is scarce. The power residing in the plant itself of reducing its consumption of water is of much more account for saving it from death by drouth than any power which the soil has of supplying it with water by simple absorption from the air. Some plants can, if necessary, lower the rate at which they take up water by their roots and give it off into the air to one-tenth of the usual rate, without showing, at least for a time, any signs of suffer-

ing; and when the supply of water at the roots is more liberal they pump away again as fast as ever.

Some substances added to the soil check very much the rate of exhaustion of the water by vegetation; salt acts thus, and plaster appears to be particularly effectual. Thus the opinion common among farmers may be accounted for, that plaster lessens the danger of bad effects from a scarcity of water; they say it absorbs water. But this is out of the question; all the ground plaster that is sold has been exposed to the air for a long time before the farmer buys it, and it has had ample time and opportunity to absorb all the moisture it can from that source. But if it serves to lower the rate of evaporation of the soil-water into the air through the vegetation growing on the soil, it is plain that it may to some extent serve the same purpose as if it did actually absorb water from the air to be handed over to the plant crops according to their needs; it husbands the scanty stock of water in the soil, and forces the plants to be more economical in the use thereof. Some experiments with salt have shown that the soil of a grass plot to which the substance had been applied contained ten days after a rain had fallen twice as much water as did an adjoining plot which had received no salt; and the plants on the former plot were growing vigorously after those on the other plot had begun to show signs of suffering from want of water.—DR. G. C. CALDWELL (in the "*New York Tribune*").

#### ROSE SHOW FIXTURES, 1886.

FOR the guidance of those Societies which have not as yet fixed the dates of their exhibitions I append the following list of Rose Shows arranged to be held during the coming season by the National Rose Society and Societies affiliated with it.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Diss Horticultural Society, at Diss, Tuesday, June 29th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Canterbury and Kent Rose Society, at Canterbury, Thursday, July 1st.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Maidstone Rose Club, at Maidstone, Friday, July 9th.

Cray Valley and Sidcup Horticultural Society, at Froggnal, Saturday, July 10th.

Wirral Rose Society, at Birkenhead, Saturday, July 10th.

East Gloucestershire Rose Society, at Moreton-in-Marsh, Tuesday, July 13th.

National Rose Society, at Birmingham, Thursday, July 15th.

West of Scotland Rosarians' Society, at Helensburgh, Friday, July 16th.

The only fixtures of Rose Shows not in connection with the National Rose Society that have as yet reached me are the two following:—

Crystal Palace Rose Show, Saturday, July 3rd.

Oxford Rose Show, Wednesday, July 7th.

—EDWD. MAWLEY, *Rosebank, Berkhamstead.*

DAFFODIL NOTES.—Much has yet to be learned in reference to Daffodils; so I would take the liberty of suggesting that your correspondents record anything that seems unusual through your columns. Though I have an almost complete collection of Narcissi, not half a dozen varieties out of doors in a warm southern aspect have yet bloomed. The dwarf little *N. nanus*, reaching about 4 inches high with me, only opened a week since. I use it as an edging to an herbaceous border, with *St. Bridgid* Crown Anemones behind. The last snow played sad havoc with the foliage and opening bloom buds of the Anemones and a few of the Narcissi, though they had escaped unscathed through the winter's frost. *N. Trumpet Major* has only opened its first bloom to-day, being preceded ten days by *N. obvallaris* (the Tenby Daffodil). Mr. W. B. Hartland of Cork last year had this last in bloom the 24th February, so that unquestionably for everything as well as for Daffodils this will be one of the latest seasons on record. Those who have the Tenby Daffodil should save the seed—it seeds freely—or cross (hybridise) it with, say, *N. cernuus*, which blooms at the same time, as I have done. As to this last, *N. cernuus moschatus*, as it came labelled to me from Holland, I think there must be some mistake. It is pure white but not Musk-scented, and therefore cannot deserve that adjective. I sent a flower last year to Mr. Burbidge, Trinity College Gardens, who considered it "not exactly like anything he had," and he has probably one of the most complete collections in the world. I find advertisements for Narcissus flowers or bulbs in several of the local Irish newspapers, especially for the single forms. I think this

commendable, as long-lost or new varieties may be thus secured, as Mr. Hartland, above named, secured Rip Van Winkle, which Mr. Peter Barr at first considered might be the double form of the Lent Lily. Rather curious bulbs of *N. incomparabilis* Leedsii, and I may add *N. bicolor* Horsefieldii, ripened; taken up, and potted here, bloomed splendidly a fortnight before those imported. This is worth remembering.—W. J. MURPHY, *Clonmel*.

#### KITCHEN GARDEN.

SPRING has come at last. Rain has fallen freely of late; the temperature, night and day, has risen rapidly, and a continuance of such weather will soon enable us to bring up all arrears. Since the snow disappeared frost ceased, and the atmosphere has become humid and mild; it is simply astonishing how much young Cabbage, Onions, Spinach, and other vegetables have advanced. They have quite regained their healthy appearance, and no one could tell that they were the same plants as were so much shrivelled in the frost some weeks ago. Where operations are much behind, as they will be in many instances, there may be a tendency to put crops in hurriedly and imperfectly, but the practice should be avoided, as it has a decided bearing on the quality of the crops throughout the year. The greatest economy results from doing everything well.

MUSTARD AND CRESS.—Where the winter has dealt hardly with autumn-sown Lettuce and other salad plants there may be a prospect of spring salading being very scarce, but a good supply of Mustard and Cress will give great satisfaction and compensate for other deficiencies. Sow the seed on the surface of inside Peach or vinery borders or in shallow boxes; growth will be rapid in any rich soil where the temperature ranges from 55° to 70°.

ONIONS.—Sowing these should be completed as soon as possible. As a rule all sorts are placed into very rich soil; indeed, it is generally considered almost useless to sow Onions in poor soil, but this is a mistake, as all Onions intended to be kept through the winter and into the following summer cannot be too firmly grown, and much sounder bulbs are produced on poor soil than in rich material. The bulbs are small in poor soil, but they mature thoroughly, and these are the qualities to insure their long keeping. Onions in rich soil grow freely and generally form large bulbs, but frequently they are thick in the neck and do not ripen well, and we would strongly advise all who wish to grow medium-sized bulbs of the highest keeping properties to sow and grow on poor soil. No good Onions will ever be grown in a shady position; in fact, they cannot be too much exposed to the sun. Allow 15 inches from row to row, sow thinly, and roll the ground firmly afterwards. Some Onions we sowed about the middle of February were kept at a standstill during the recent severe frost, but they are now showing all along the rows. Where seed was sown in boxes under glass harden off the young plants as soon as they are 4 inches or 5 inches high, that they may be ready for planting out in a few weeks.

POTATOES.—It will now be safe to plant these in all parts of the country, and garden and all early crops should be placed in as soon as possible. Use plenty of ashes and leaf soil where the soil is heavy, and where manure is scarce a sprinkling of guano round each set is good. As soon as the young shoots appear above ground on the early border or elsewhere draw a little soil over them to keep them under cover and away from frost as long as possible.

GLOBE ARTICHOKE.—These are just beginning to grow. Where light material was put round them as protection in the autumn move this away and supply rich manure. Do not fork or disturb the roots, but as the manure is washed down to the roots they will receive the full benefit of it.

BET.—The seed and young plants are somewhat tender, but where the supply of old roots is deficient young ones should be secured as soon as possible, and a few short rows of the Turnip-rooted variety may be sown. This is much earlier than any of the long-rooted sorts, and the bulbs will be ready for use in about two months after sowing.

JERUSALEM ARTICHOKE.—These should be grown in every garden, as they are most simple in culture, productive in results, and useful. They may be grown in almost any soil or in any situation. A peck or two of seed should be brought in now and planted, and where they do exist lift every one of them. Select all the large ones and store for use, but the smaller tubers should be replanted. As they grow tall from 2 feet to 3 feet should be allowed from row to row, and 1 foot from set to set. They should be planted like Potatoes, and from 4 inches to 6 inches below the surface.

PEAS.—Autumn-sown Peas will, in many instances, be a failure this spring; ours have suffered severely, but some of Ringleader, which were sown in the open in the first week of January, are 2 inches high and looking well. Others which were sown in turves under glass since then are 3 inches and 4 inches high, and they are now in a cold frame with the lights off during the day and only on at night; and if we could make sure of the weather we would plant them out, but remembering past experience we will keep them in for another week or so; but all Peas raised under protection should now be hardening, and great care must be

taken that this is not done too quickly or they may be checked and their earliness fail to be an advantage. Sow more seed, earth up, and stake all early crops.

BRUSSELS SPROUTS.—These have withstood the severe winter better than any choice winter green; and as they are such an excellent vegetable from October until April they should be grown by all. Many small garden owners shun them under the impression that they are difficult to grow, but they are no more so than Cabbage, and should just be as common. Two or three years ago we advised the head gamekeeper to try a batch in his garden, and he was so well pleased with the growth they made, and the long succession of excellent vegetables he secured from them at a season when he was often without green vegetables, that they have become a favourite winter crop. The secret of having them good is to sow early and have the plants well up by June or July; then they have the autumn to form the sprouts. The first week in April is a good time to sow. A seed bed a yard square or thereabouts will furnish many plants, and when sown together in a small patch it is a simple matter to transplant them into their bearing quarters when they become large enough to be put out.

PARSNIPS.—Some sow these very early, but we have generally found those sown in April as good as those sown in January or February by the time November came, which is early enough to have Parsnips ready. The Student is our favourite variety. It is not so large as some, but it is first-rate in quality. Moderately rich, not very stiff soil suits Parsnips best, and the rows should be 18 inches apart at least. There is no use, however, in attempting to get fine long roots from shallow soil; and where the soil is not more than 1 foot in depth we would advise the Turnip-rooted variety to be grown. This is really a useful little-known variety.

SEAKALE.—Where plants were taken up to force and were put into pots and boxes they should be hardened off in these, and as soon as the young growths which are being emitted from the crowns are capable of bearing exposure plant them. Those which we are planting now will come in for forcing again the winter after next. Where the crowns are small they are planted without being disturbed, but where they are large and several shoots are growing on each they may be split into pieces, each one with a growth on the top, and plant in this way. The soil can hardly be too rich for them, and they should be put in rows, allowing 15 inches from plant to plant and 3 feet from row to row. Roots which have been forced in the ground, and are too close together, should all be taken up and replanted.

#### FRUIT FORCING.

MELONS.—Stopping, thinning, and tying the shoots will require frequent attention, which must be timely, as if neglected for only a few days the shoots will become overcrowded. Plants swelling their fruit will require water at the roots, and if bottom heat be afforded by hot-water pipes a thorough soaking should be given. If the roots of the plants are in shallow or narrow borders, and drainage ample, tepid liquid manure in a weak state should be applied whenever the application of water to the roots is necessary, which will, in a great measure, compensate for the limited root-action. Ventilate in accordance with the state of the weather, commencing at 75°, or at 70° on fine mornings, and increase it with the rising temperature, maintaining the temperature at 65° to 70° at night, 70° to 75° by day from fire heat, and 80° to 90° in the daytime from sun heat, closing at 85° to 90°, and so as to run up to 95°, with plenty of atmospheric moisture, a high temperature with plenty of moisture being essential in houses or pits where Melons are swelling. Support must be given the fruit in good time, a piece of half-inch thick deal board, 6 or 7 inches square, and suspended in a sloping position so as to prevent the water lodging, securing it by four pieces of wire from the trellis. Succession plants will need constant attention in training and regulating the growth. Train with a clear stem to the trellis, rubbing off the side shoots so soon as discernible, and do not stop the leading shoot until it has grown two-thirds across the trellis. Every alternate lateral on opposite sides of the leading shoot should be removed, and this will prevent the crowding that is too often allowed. The laterals will show fruit at the second or third joint, and should be stopped one joint beyond. A somewhat dry atmosphere should be maintained where the plants are in flower, and until they have set their fruit, impregnating the flowers every day as they expand, until a sufficient number are obtained on each plant of the same stage of growth. In pits and frames where the plants are trained over the surface of the beds young plants will need stopping at the second or third leaf, and the shoots resulting being reduced to four, train two to the front, and a similar number to the back of the frame, stopping them when a foot from the sides. It will be necessary to thin or rub off the laterals to some extent so as to prevent overcrowding, and fertilise the flowers, stopping at the same time one joint beyond the fruit. The linings of dung frames will require to be looked to weekly, or at such intervals as circumstances occasion, and protection over the lights will be necessary at night as a means of retaining the heat by preventing radiation from the glass. Sow and plant in accordance with the requirements of the establishment.

CUCUMBERS.—If fine fruits are desired crop lightly and place the fruit in glasses to grow clean and straight. Plants in vigorous growth, and the soil being rapidly filled with hungry roots, will be benefited by copious supplies of weak tepid liquid manure. Maintain a moist and genial atmosphere by damping frequently and syringing at closing time. Ventilate a little early to dissipate any moisture that has accumulated through the night, and keep the temperature through the day at 80° to 85° with sun, closing sufficiently early to raise it to 90° or 95°. Attend to stopping, thinning and arranging the shoots so as to keep up a

succession of young bearing wood. Where the demand is not very great a good supply of fruit can be obtained with several two or three-light frames by planting the Cucumbers in succession and cropping lightly. When the second frame plants come into bearing thin most of the old shoots of the plants in the early frame, and induce the plants to make young wood, which will, in its turn, make a succession to the second, and so proceed with each frame in successional order.

**STRAWBERRIES IN POTS.**—The season for fine forced Strawberries will soon be at its height and the labour entailed at its maximum. Dry east winds are very prevalent in spring time, and great attention must be given the watering. The plants should be examined at least three times a day in bright weather, and whenever a plant needs water give a thorough supply. The shelves at this time of year should be at a greater distance from the glass than is advisable earlier in the season, so as to allow a free circulation of air between the leaves of the plants and the glass, the flowers not being exposed to violent atmospheric changes on the admission of air after a period of dull weather. Plants that are to give very fine fruit should not only be those showing the largest flowers, but those must be thinned to about a dozen or so on each plant before they expand. Bring them forward in a gentle heat in the first stages of swelling, affording an abundance of atmospheric moisture so long as the fruit remains green; but when it becomes whitish green increase the temperature gradually to 80°, 85°, and 90° on sunny days, keeping through the night at 65° to 70°, with 5° more on dull days or from artificial heat, continuing this until the fruit becomes red all over, when the temperature should be lowered to a minimum of 60°, in which they will increase considerably in size even after they are apparently ripe, and to secure high flavour a free circulation of warm rather dry air must be maintained, watering at the roots being dispensed with as much as possible for two or three days before the fruit is gathered.

#### PLANT HOUSES.

**Zonal Pelargoniums.**—To have these in good condition for winter, cuttings may now be rooted. Healthy cuttings should be inserted singly in small pots, and if kept moderately moist will root quickly on a shelf in a temperature of 60°. As soon as the plants are rooted remove them to a temperature of 5° or 10° lower to encourage a dwarf sturdy growth. When the small pots are full of roots the plants may be transferred into 3-inch, and finally into 6-inch pots. By the time they are placed in the last size they should be growing under cool conditions. Pinch the shoots from time to time to induce branching. The soil must be pressed firmly into the pots, the most suitable soil being fibry loam, one-seventh of manure, and a little sand. Double varieties required for yielding trusses for cutting during the summer months may now be placed in 7-inch pots. The earliest plants for this purpose are bushy specimens in 5-inch pots, which are now full of roots, and have again started freely into growth after having their shoots pinched. These, after potting, will be allowed to flower. Later plants in the same size pots should now be pinched, and when they have commenced growth they will be ready for potting. If there is any deficiency in the stock of these plants insert strong cuttings at once, placing three or four into 60-size pots, and then grown on together without stopping the shoots.

**French and Fancy Varieties.**—The earliest of these will be coming forward rapidly, and if placed in a temperature of 50° to 55°, will commence flowering before the end of next month. Care must be taken to ventilate daily when the weather is favourable, or the flower stems will be drawn up weakly. If the pots are full of roots weak stimulants may be given every time the plants need water, or a little artificial manure to the surface once a fortnight. Grow the second batch close to the glass, in a temperature of 45°. These must be watered carefully, and the shoots allowed to extend after this date. Large plants must have their shoots tied out before they become crowded. The third plants may be placed in the pots in which they are intended to flower, and when they have commenced rooting in the new soil pinch the shoots and tie the strongest out towards the rim of the pots. Cuttings may now be rooted for late flowering. The cuttings on leggy straggling plants may be utilised for this purpose. They may be rooted under the same conditions as Zonals. Pinch them once, and then place them in 4-inch pots and allow them to flower. If green fly appears fumigate at once lightly with tobacco smoke.

**Nicotiana affinis.**—Young plants from seed sown some time ago will now be ready for placing in 3-inch pots. They will grow well in any fertile soil, and should be grown on in a temperature of about 50° if wanted in flower as early as possible; if not, grow them on under cool conditions. When the 3-inch pots are full of roots place the plants into 6-inch pots, a very suitable size for them. The blooms of this plant are highly fragrant and most effective when arranged to rise above other dwarf flowering plants.

**Tropaeolums.**—Double and single climbing varieties should now be propagated and grown for furnishing the roof of greenhouses, conservatories, and other structures. When planted out in good soil the plants grow rapidly, covering a large space, and are most effective when bearing their gorgeous flowers. They must be grown on under cool treatment, or their shoots become weakly and the plants fail. These plants do well in good loam, to which is added one third of leaf mould and manure with a little sand.

**Coleuscs.**—Propagate these in quantity, and grow them on for conservatory decoration. A number of these plants will be very useful after spring bulbs and Azaleas have flowered. For those forms of decoration bright-foliaged varieties should be selected, and those that naturally keep their colour even when the structure is shaded to suit flowering plants associated with them.

**Achimenes.**—Cuttings will now be plentiful from the tubers started some time ago, and the first batch should be inserted without delay. Very useful plants for conservatory decoration can be grown in 5-inch pots. These should be moderately drained and filled with a compost of loam, one-third leaf mould, and one-seventh of decayed manure and sand, with a liberal dash of the latter on the surface. Insert cuttings in these about 1 inch apart, then well water them and place them in the propagating frame, where they will quickly form roots. They will root freely in any structure where a temperature of 60° to 65° can be maintained in a shady position, but they root more quickly in the frame. The plants from which the cuttings are taken will soon break again into growth and produce others. Cuttings may be rooted in pans filled with sand for making up baskets, which are very effective. After the cuttings are rooted do not grow them too warm or they will become tall, but if grown in an intermediate temperature will flower from the base.

**Amaryllises.**—Seedlings or small plants that are not wanted for flowering, or any that it is not necessary to retard for flowering late in the season, may now be started into growth. These should be taken out of their pots, the old soil shaken from the roots, and repotted in fresh fibry loam, one-third leaf mould, a little decayed manure, and sand. These plants do not require very large pots, and in potting the bulbs should be well above the soil. The soil must be pressed firmly into the pots. If practicable plunge the pots in gentle bottom heat derived from leaves or other fermenting material. A pit is a good place for them, with a hot-water pipe running round, so that a steady temperature of 50° can be maintained, which will insure a sturdy growth of foliage if they are arranged moderately close to the glass. Water carefully at first, but syringe freely twice daily when the weather is favourable.

**Tuberous Begonias.**—These may now be started, and very few plants are so useful for the conservatory during the summer. The old soil may be entirely removed from the tubers, which should be placed in boxes amongst leaf mould until they start into growth. If the boxes containing them can be stood upon a hotbed where a temperature of about 60° is maintained they will soon commence growing and rooting. They root freely in leaf soil, and can be lifted out with a ball of fibry roots, when it is necessary to place them singly in pots of various sizes according to the size of the tubers. After potting, grow the plants in an intermediate temperature where air can be given liberally when the weather is favourable. These Begonias grow freely in any light rich soil; in fact, we give them the same compost as Achimenes.

**Paneratiums.**—Pot these before they start into growth. The old soil should be shaken from their roots, for it becomes sour in the space of a season, and repot the plants in fresh. Drain the pots liberally, and do not employ too large a size. The soil (fibry loam, sand, and manure) should be rendered firm and the bulbs left well above the surface, so that they will have a chance to swell. After potting shade from bright sunshine, water carefully, but syringe the foliage liberally, and they will quickly recover and commence rooting freely. *Hymenocallis macrostaphana* is a beautiful plant and worth a place in every stove. It requires the same treatment as *Paneratium fragrans*.

**Urecolina aurea.**—A few good pans or pots of this are worth a place in any garden, for the plant is very effective early in the year; in fact, with a good stock of plants their flowering season can be extended for some time by starting some at intervals of a few weeks. We have found it a good plan to shake them out annually after they have flowered and repot them in loam, leaf mould, and sand. The object after flowering is to produce a good leaf growth. They will do well in any moderately warm structure where they can be shaded from the sun.

## THE BEE-KEEPER.

#### USEFUL HINTS.

THE feathered songsters, together with the bees, have again welcomed the return of spring. The cheerful song of the one with the joyful hum of the other will be pleasing to all, while the unfolding flowers will be searched and rifled of their pollen and nectar by the industrious bees.

#### EXAMINATION.

Immediately the bees have aired themselves make a thorough inspection of all parts of the hive for damp. If any exists trace its source. As I have stated often, the exterior of hives should be free from any obstruction to water that is likely to allow the wind to turn it inwardly, or the absence of a proper drip leads to the same evil, as do also horizontal joints, such as dovetailing or double joints, which draw water by capillary attraction. If any of these evils exist cover dovetailed or badly jointed corners with thin corner-pieces, which can be cut cheaply in one piece from a block of wood. Bed these in good white or red lead paint, and nail closely.

## ROOFS.

Wherever these have been made with plinths better to discard at once and make new ones of a good depth to go outside the hive, working telescopically with thin wood, nail on the top, and cover with zinc. The zinc and workmanship for covering a hive will not exceed 8d. The zinc must come over the sides a little, which forms a drip, and when fastened properly at the corners to allow for expansion or contraction never becomes unsightly. I have had these roofs in use for thirty years and are still good. They are light and cheap, and if thorough ventilation has been secured efficient, which no wooden roof is, unless it has been protected by waterproof material. None of this is so cheap or efficient as zinc, which does away with frequent painting, which is expensive.

## MAKESHIFT COVERS.

Every bee-keeper should have a supply of these constantly on hand to meet emergencies. Many a swarm I have seen destroyed for the want of a waterproof covering on the suddenness of a thunder shower coming on while the bees were beginning to cluster, which would have been saved by the timely appliance of a sheet of iron or zinc. These, too, are useful for covering extra hives in summer, and are indispensable in many cases when at the moors. The following are what I have had in use during my bee-keeping career:—Felt, which can be bought for less than 6d. per yard when well tarred, and as much powdery lime pressed into it as it will absorb, makes a lasting cover. Lime seems to petrify, and the felt seems to become everlasting after being so treated. Covering felt with sand, as so often recommended, is of little use. After using felt for ten years I have had it buried for as long a term, and when taken up have used it again. Painted or tarred paper are handy makeshift coverings, but do not act so well if fastened to wood, as its shrinkage is liable to rend the paper. Good canvas thoroughly painted, laid on a bed of paint, and occasionally painted afterwards has lasted for seventy years, and some I saw done in this way forty years ago is still waterproof. Zinc galvanised, plain and corrugated iron, are all cheap and useful, and if the latter could be had in sheets circled of the right size for hive roofs there is nothing better. The corrugations admit a free circulation of air, keeping the upper part of the hive cool in summer and dry in winter—the essential points towards profitable bee-keeping. Canvas of any sort tarred or painted is a good temporary covering, but is soon cut, and is liable to create damp. Other coverings I have seen, but the foregoing are the cheapest, and what I have found serviceable in the apiary as well as the garden.

## DYSENTERY.

Should any of the bees show signs of abdominal distension, brought on by cold and damp through defective hives or disturbance, take immediate steps to put matters right whenever a fitting opportunity occurs, which is when the day is fine and the bees from healthy hives are flying. In all cases where the ordinary and moveable floorboards are in use, these removed, and clean dry and heated ones substituted, will greatly strengthen the bees and enable them to fly and return safely to their hives. If this occurs with bees in hives with fixed and damp combs, ventilate from below and above by placing an empty box on the top, carry the hive of bees into an apartment having a brisk fire, and keep them there until the bees outside are again flying, then place them on their stand. By this process the hives will be made drier and more genial for the bees. With frame hives it will only be necessary to transfer bees and combs into a dry and empty hive, unless the combs are the worse from damp. In such a case it will be advisable to supply the bees with dry ones, either from combs kept for the purpose, or of those from other hives that can spare them. It is to be hoped that there will be few cases requiring such treatment: there should be few, if previous instructions have been attended to. Occasionally, however, from unknown causes, a chance case may occur in which the above treatment will greatly mitigate the evil. In

fact with healthy bees it is beneficial to assist them in their first flight when it can be done with a little artificial heat. Those hives having a dropping bottom with ventilating floor, a thin firebrick slightly heated and placed on bottom, then closed to zinc, has proved beneficial.—A LANARKSHIRE BEE-KEEPER.

## FEEDING BEES IN THE SPRING.

## UNSEALING CELLS—INCREASING SPACE.

WILL some practical bee-keeper inform me if it is necessary to feed bees in the spring if there is plenty of uncapped store in the hive, and should anything be done to promote an increase of bees? Shall I be doing right in unsealing the cells to allow of the bees consuming the honey, thus providing additional room for the queen to deposit eggs and raise brood? A little advice on the above will oblige.—A NOVICE IN BEE-KEEPING.

[If bees have a sufficient store of honey in the hive now, say not less than 12 lbs., or if the hive is of sufficient size, there is no advantage gained by feeding; nay, it is detrimental when it can be avoided. Uncapping cells is also a great mistake and wasteful of honey, as well as wearing out the bees, causing loss amongst them by inducing them to fly out.

If your hive is not large enough to contain 30 lbs. of honey independent of breeding space it is too small, and you should take immediate steps to increase its size. Horizontal sections or divisions, as in the Stewarton, is the proper way to accomplish that. Some people have an idea that bees require open ventilation above. This is a great mistake, and simply destroys them wherever it is resorted to. It is also damaging to hives when the crown of the hive is rendered non-porous. As bees carry on breeding at least nine months in the year the covering should always be uniform, ample to retain the heat, but so that vitiated air may pass through the covering without causing a draught, but not overmuch, or the moisture may condense and fall back on the bees and honey, chilling the former and rendering the unsealed honey unwholesome and likely to lead to disease.

Where the bees have dwindled to a mere handful these should be at once confined into space consistent with their powers of breeding; but wherever hives have been managed in a thoughtful manner they should require little or no attention until swarming time beyond cleaning floors, giving peameal and water where these necessities are scarce in the apiary during spring. I think the foregoing covers the questions.

The following gives conclusive evidence that long experience is the best guide. On the 7th of February there was a slight relaxation of the severe winter weather, when a few of our bees flew out without much loss amongst the snow, as I had it cleared away from the front of the hives previously. Young bees aired themselves in great numbers. After that the weather turned more severe, the thermometer sinking to 7° in March, and snow fell every day, unless three, up till the 20th March, or in other words it snowed for ten weeks. On that date the snow was thick with much ice, which the rising temperature of that day began to dissolve. The bees now began to fly, but it was not till the following day that they were enabled to have a thorough airing. From the large percentage of youthful bees showing at all the hives, together with the preserved old bees, as well as young drones at some of them, they are in a fit state to gather surplus honey at the earliest and first opportunity. This means that feeding, uncapping cells, spreading brood, &c., are unnecessary to promote breeding. That depends upon autumn management, by having a young mother, plenty of bees, a roomy hive of proper form free from damp, and containing plenty of stores, means for keeping up a free circulation of air throughout the hive without creating a draught, and a sufficient quantity of dried grass on the top to retain the heat, but not so much as to cause the perspiration to condense and fall upon the bees. I have several hives in my apiary that have not shown a bee dead or alive from the end of October till the 21st day of March, yet these are healthy, have had no loss, and are far advanced with brood. They are Carniolian bees, and are in deep hives and in such an advanced state that it is impossible to interfere with them without injuring them. The only thing required is not to allow such hives to have less than 12 lbs. of honey in store until the honey season sets in. I have, perhaps, gone beyond the limits allowed for answering queries, but I considered that a brief description of the state of my bees would be interesting to more than "A Novice," and encourage and induce them to adopt proper forms of hives with consistent management, without which success cannot be obtained.—LANARKSHIRE BEE-KEEPER.]

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or

members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**TO CORRESPONDENTS.**—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Liverpool Horticultural Association (J. W.).**—Mr. E. Bridge, 3, Cedar Terrace, Huyton, Liverpool, is the Secretary of the above Association. Butterflies have been seen in warm localities since the favourable change in the weather.

**Marsh Mallow (T. N.).**—You ask if this plant belongs to the Cranesbill or to the Hollyhock. Generically it does not belong to either, but is classed in the same natural order as the Hollyhock—Malvaceæ.

**Camellias (J. C.).**—The culture of Camellias has been frequently and fully described in our columns, and if you preserve the back numbers you will find an excellent article on page 153, February 19th, 1885. There is no pamphlet such as you appear to require. If you can make the actual condition of your plants clear to us, and state your means of growing them, we will readily advise you on their management.

**A New Insecticide (W. R. B.).**—The formula to which you refer is not Professor Church's, and our report does not state he gives it to the world. He brought the preparation to the notice of the Scientific Committee of the Royal Horticultural Society, and explained he had no interest in it except a scientific one. It is a proprietary invention, and will presumably be manufactured for sale, and, therefore, no doubt advertised. We are not in possession of the formula.

**Protecting Fruit Blossom (E. B.).**—By all means affix the blinds, especially as they can be "so arranged as to be drawn up and let down as required." That is the best plan undoubtedly. It does not at all follow that because the weather is now so mild that it will remain so, and sharp frosts or cutting winds may yet occur to injure the blossom on your Peach trees. It is wise to expect that adverse weather changes will be sudden, and to be provided accordingly. Blossom is often injured by thick permanent coverings in mild weather, but at the same time it is to be remembered that a crop of fruit may be destroyed in one night. Where moveable blinds are provided and judiciously used it is not often the blossom so protected fails to set. The young fruit also needs protection from frost. We have known Peaches and Apricots destroyed when as large as Nutmegs.

**Market Garden Ground (W. J. R.).**—Good market garden land at £4 per acre well cropped and managed ought to afford a good return to a person with sufficient capital, which ought not to be less than £20 per acre, and with a good practical knowledge of gardening; but much depends upon the condition of the land. If poor or exhausted by the outgoing tenant it will need a considerably larger amount of capital for manure, and the value of the crops would be lessened for a time through their not being heavy nor of such quality as to bring the best prices in the markets. Then if the land be foul or weedy state it will add to the capital necessary to clean it and correspondingly take from the profits; it will make a considerable difference also if the land needs draining, and further in the method of cultivation adopted, for if the land has been under plough and you put it under spade cultivation the capital needed will be considerably more than were you to keep it to the plough. Then you make no mention of buildings, which must or ought to exist on a ten-acre plot, and means of working, conveyance of goods to and off the land, with nearness of market will have to be taken into account, these being matters for serious consideration. With the land fairly clean and in good heart we think it would pay good interest on the capital invested, providing average management is exercised in cultivation. We think land at £4 per acre is too good for poultry and rabbits; or if not, it is not worth £1 per acre for market gardening.

**Tacsonia Dying (W. L., Co. Down).**—Your plant that "flowered profusely yet grew very little" was in a very enfeebled state, the flowering being as it were a last flicker of life—a sort of gasping yet futile effort of the plant to perpetuate its species by the production of seed before it died. Its cankered stem, a portion of which you have sent, shows that very little sap could be supplied by the roots, the channels through which it should pass being either obstructed or decayed. It is certain it would not have lived long in the absence of frost, but this undoubtedly accelerated its death. You were therefore not far wrong in your verdict. We suspect the stem has sustained injury at some time, which predisposed it to decay, and we do not think the origin of the evil was in the soil.

**Dissolving Bones (W. A.).**—There is a slow and a quick method of reducing bones to powder:—1, Take a large watertight hogshead, and cover the bottom with about 6 inches deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full. Leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshead the bones will crumble to powder under a slight pressure and form one of the most valuable manures ready for immediate use. 2, Place the bones on an earthen floor surrounded by

a rim of ashes. Pour on as much water as the bones will absorb, and then pour on sulphuric acid, about 2 lbs. sufficing for 5 lbs. of bones. It will boil somewhat violently for a while. When this has subsided it will get tolerably solid. The ashes and all may then be shovelled up together, and will be fit for use in a few days.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (A. Y.).—1, *Celsia Arcturus*; 2, *Alonsoa Warscewiczii*.

**Barleysugar (R. C.).**—The barleysugar is a fairly serviceable sample, and will be readily made use of by the bees. It has been a little over-boiled. When making the next keep testing to see whether it is done by pouring a little on to a cold surface. If on cooling it becomes crisp and brittle, and very slightly sticky, it is ready for removal; if soft and sticky it requires more boiling. Syrup should now be used in preference to candy in all cases where food is required.

# COVENT GARDEN MARKET.—MARCH 31st.

MARKET with little alteration. Grapes lower. Trade better.

## ROOT CROPS.

It has been said of Mangolds that even when at the best, as they are at this season of the year, they will not fatten

cattle or sheep. We may qualify this assertion, and say that Mangolds alone will not fatten animals either fast enough or sufficiently well, but they are an excellent, and, in the opinion of many farmers, an indispensable addition to the food of all animals of the farm now. Valuable as Mangolds undoubtedly are, it is a mistake to regard them as quite indispensable, and when the small store of this season is exhausted, to sell animals at a sacrifice as we were asked to do by one of our bailiffs. With a liberal diet of crushed corn, cake, and chaff, and pure fresh water, we can dispense with Mangolds, but we never would do so except from necessity. Happy is he who has more than he requires, for the price has reached the abnormal height of 25s. per ton. What say they to this price who assert that 15s. per ton is the actual value of Mangolds as an article of food? Well will it be if the short supply of Mangold teaches us never to depend too much upon any particular crop, but rather so to apportion the land at our disposal that there may be a fair proportion of all useful crops.

Kohl Rabi, if grown on ridges prepared precisely in the same manner as for Mangolds, should find a place on every farm, for its nutritive value is high, its culture easy, it bears transplanting well, and withstands the effects of drought in a remarkable degree. With it too, early sowing is all-important, as enabling it to become well rooted and to grow freely before the extreme heat of summer begins. The risk and labour of transplanting have led to drilling, and the seed can now be had sufficiently cheap to enable us so to use it. No doubt Kohl Rabi is a greedy plant, requiring a rich store of fertility in the soil for its full development; but it is certainly not more so than the Mangold, and it should take rank with it as an article of diet, and precedence of the Swede both for nutritive value and certainty of a crop. It is this certainty which adds so materially to its value; once get the plants established in soil stored with the requisite elements of fertility, and they answer so well that we have known instances of its adoption as a substitute for the Mangold, which, owing to a failure or two, was considered unsuitable for the soil. Well would it be if farmers were not so generally predisposed to take things for granted, but would rather persist in proving for themselves why certain crops answer or otherwise. Knowledge so gained is invaluable, and while avoiding costly speculative experiments, we are certainly justified in striving for improvements which shall render results more certain and more profitable.

It is our agreeable privilege to own that we were successful in our Swede culture last year, and we have found the roots most serviceable. The earlier-sown Swedes were cleared off the land and put in clamps for the hoggets, the later sowings were left out upon the land, and we are now folding ewes with forward lambs upon them. The lambs run forward and give ample proof of lusty appetites by eating many of the Swedes level with the surface before the ewes are let in to clear up the remainder of the roots which are pecked up for them. Why is it that so many farmers in the southern and midland counties wait till June before sowing the Swedes? We saw a field of Swedes last year which was sown at the same time as the Mangolds, and the roots were very fine, much finer than any other Swede which came under our notice. All things considered we prefer May for our first sowings, and then follow with a June sowing for folding as we are doing now. The land then comes nicely to hand for successional crops of spring Tares, on which the sheep are again folded, and the land is subsequently in admirable condition for a Wheat crop, being ploughed early, so as to be ready for the first sowing by the end of September. Not unfrequently, however, advantage is taken of its high state of fertility for a crop of winter Beans, which we invariably sow early in autumn.

White Turnips, though low in nutritive value, are very useful, and we gladly welcome two or three successional crops for the sheep. We generally have a field or two at this season of the year, with nice green tops for the lambs, but, alas!

our wintry March weather has destroyed the tops which were green enough in February. May, June, and the two following months should each afford us a crop if land can be had and the weather is favourable. We failed to obtain any early White Turnips last year, and we know a farm where a field was sown three times in vain, and there were no White Turnips on that farm. We never fold sheep solely upon a diet of Turnips, but always give dry food in troughs, not as a simple matter of course, but according to our invariable practice of promoting quick growth and early maturity in the sheep.

Carrots are grown principally for the dairy cows, our aim being to secure enough for stall feeding during the last three months of the year. We sow early in April upon a fine clean seed bed, the thinning is done early, in order that the hoes may be soon at work to keep under weeds.

#### WORK ON THE HOME FARM.

At last winter is gone! and we have delightful spring weather for sowing the spring corn. All was in readiness for the change, and the work goes on so briskly that by the time this note is published most of the corn will be sown. We have five farms in hand, and our arrangements for spring work required much care and forethought. Due care had to be taken to have the best seed, to procure manure in due proportion according to the condition of the land, not only at each farm but in each field. As we have gone about upon the farms during the past week we had the gratification of finding our plans being carried out so well that we may reasonably hope for success. The seed drills were in full activity; the soil mellow, and fine as a dust heap—aye, even upon so-called heavy land farms required far less labour than usual either in the drilling or harrowing. The artificial manures, procured from various sources, were mixed in one huge heap at each farm, and the sowing of it upon all crops was being done. We were amused by the account of one of our bailiffs of the sensation caused in the village near his farm by his six-horse waggonload of bags of manure. Never had such a sight been seen there before, and the farmers declare it is a mere waste of money. We are not surprised, for have they not good reason to regard such manure with suspicion? Well, we hope to prove to them we are right both for their benefit and our own profit. Attention is now being given to the preliminary measures for root crops. The farm and manure heaps are ready, and the other manures are ordered. We have had some little difficulty in obtaining bone flour in the only condition we use it, which is absolutely as fine as flour; and impalpable powder, which by the minute division of its particles is precisely in the best condition for speedy action as plant food. After an explanation of our requirements, our reasons for them, and our willingness to pay for extra grinding, we had no further difficulty about the matter.

The ewes and lambs now being folded upon Swedes will, we fear, have finished them before the Rye is ready, and we may have to turn them upon meadow grass for a week or two. Our liberal diet of mixed trough food will be continued, as we wish to force on the lambs and to dispose of them early. Every week our conviction grows stronger of the fallacy of keeping store cattle or sheep, except for breeding. Lambs sold in July even at 30s. apiece must be more profitable than hoggets sold at eight or ten months later at 40s., and there can be no question that this is frequently done, but it is hardly possible that those who persist in doing it look very closely into details.

#### REMARKS.

21st.—Dull till 11, then fine and warm.  
22nd.—Overcast.  
23rd.—Dull and showery morning, fine afternoon, but no bright sunshine.  
24th.—White fog early, fine bright day.  
25th.—Cloudy morning, fine after.  
26th.—Alternate cloud and sunshine, rain in evening and night.  
27th.—Dull and drizzly morning, fair after, with strong wind.

The sudden change which occurred on the 18th has proceeded with exceptional rapidity, the temperature this week being 20° higher than that of the week before last. The only approach to so sudden a change which I can trace for some years past was between March and April, 1883—the maximum temperatures rose in the last two weeks of March and the first of April exactly as much as in the two weeks just past—viz., 19.7°. But in 1883 the nights remained cool, only rose 6°, while this year they have risen 0.8°. It must be long since so great a change of mean temperature has occurred, and it is noteworthy that there has been very little change in the barometer, and very little rain.—G. J. SYMONS.

### INCURVED AND JAPANESE CHRYSANTHEMUMS AT THE NATIONAL CHRYSANTHEMUM SHOW.

**A**T the splendid exhibition held in November last by the National Chrysanthemum Society at the Aquarium, Westminster, I took down, with the assistance of a friend, the names of all the flowers that were staged in competition in those classes devoted to the incurved and Japanese varieties. The number of the former I find to have been 839, while of the more popular Japanese there were 835, thus making a grand total of no less than 1674 blooms in these two sections alone. The incurved were represented by, altogether, 82 different varieties, and the Japanese by 136 varieties. Certain sorts, of course, appeared under several different names, but these cases were by no means numerous, and it being contrary to the regulations of the National Society for any synonymous varieties to be shown together in the same stand the following analyses are in no way affected by them, all synonyms having been tabulated under but one name. Making all reasonable reductions on the score of duplicates there still remains a singularly large number of sorts from which to make a selection which have proved themselves capable of producing exhibition flowers. From the foregoing particulars it will be seen that this was a very extensive and thoroughly representative exhibition, and one well suited for the purposes I had in view.

As to whether the lists which follow give the precise relative positions of the leading Chrysanthemums in the two sections, only the accumulative results of several similar analyses can determine; but that they are there placed, with at any rate approximate accuracy, cannot, I think, admit of much doubt.

It may be of interest to dwell for a moment or two on some of those marked differences between the incurved and Japanese Chrysanthemums which are shown in the two lists. For instance, on glancing down the dates of introduction the more recent character of the latter becomes at once apparent. Indeed, taking the first thirty-six dates in each case, the average date of the incurved comes out as 1868, and that of the Japanese, omitting *Soleil Levant* as 1878, thus showing a mean difference of ten years. Or, looking at this matter in another way, there will be found only four sorts among all the incurved that have been sent out since 1879, whereas, taking the same number of Japanese, there are as many as eighteen which have appeared since that year. These dates further show how much more rapidly improvement is going on in the latter case than in the former. Not that the incurved are by any means as much at a standstill as some would have us suppose, as is indeed proved by the fact that half of the eight leading flowers are respectively only four, five, and seven years old. The number of sports in the incurved section as compared with the Japanese is very remarkable. But admirable as many of these are, they can scarcely be expected to lead to an advance in the direction where it is generally agreed that advance is most needed—

viz., towards the realisation of flowers which require but very little, if any, skill on the part of the dresser to make them presentable on an exhibition table.

The prominent positions which have been so soon obtained by some of the newer varieties in both sections is very surprising, and at the same time very encouraging. For instance, as regards the incurved, *Lord Alcester* (1882) stands No. 3 in the analysis, *Jeanne d'Arc* (1881) No. 6, and *Lord Wolseley* (1882) No. 7. Among the Japanese we find *Madame C. Audiguier*, although only seven years old, taking premier place; while more remarkable still, that extremely dark beauty, *Jeanne Délaux*, which only came out in 1882, follows her very close for first honours; *Mdlle. Lacroix*, only six years old, running into third place in a neck-and-neck race with *Fair Maid of Guernsey*. The best of the 1883 varieties in this division appear to be *Monsieur Astorg* (No. 10), *Monsieur Tarin* (No. 12), *Monsieur Henri Jacotot* (No. 16), *Flamme de Punch* (No. 17), *Margot* (No. 17), *Rosea Superba* (also No. 17), and *Monsieur Moussillac* (No. 20); while several of the 1884 flowers already take fairly good positions—viz., *L'Incomparable* (No. 14), *Madame de Sévin* (No. 16), *Mr. John Laing* (No. 16), and *Fernand Feral* (No. 21).

The premier flower among the incurved, the *Empress of India*, is one of the oldest in cultivation, being nearly thirty years old. Its history is somewhat remarkable, for it appears that it was raised by a Scotch gardener, name unknown, and brought out by Messrs. Downie, Laird, & Laing as *Lady St. Clair*, and under this title received a certificate from the Royal Horticultural Society. Some time afterwards a few well-grown flowers of the same variety were submitted to this Society by another grower as those of *Empress of India*, and to these another certificate was awarded. As showing how entirely the higher designation has ousted its original and true title, I may mention that throughout the whole exhibition at the Aquarium I did not come across one flower named *Lady St. Clair*; neither was there a single *Snowball* or *Mrs. Cunningham*, and only one solitary *White Queen*, these being other names by which this grand variety is said also to be known. In the National Chrysanthemum Society's catalogue—which I am pleased to hear is now undergoing a most searching revision—*Lord Alcester* is only to be found under its synonym of *Princess Imperial*, and yet so much better is it known by its newer name that there were only three *Princess Imperials* staged to thirty-nine *Lord Alcesters*; and in the same way only five *Mr. Howes* to thirty-seven *John Salters*, only one *Madame Madeleine Tezier* to twenty-eight *Jeanne d'Arcs*, and only one *Princess Alexandra* to twenty-eight *Princesses of Wales*. In the Japanese section, however, the name of *F. A. Davis* occurred no less than ten times.

As to the lists of dates and raisers' names which I am now able to give, I think I may claim in their behalf that, notwithstanding some imperfections, they still remain the most complete and accurate of the kind that have yet appeared. For the valuable information they contain I have to express my great indebtedness to Mr. N. Davis, Camberwell; Mr. John Laing, Forest Hill; Mr. Orchard, Kingston-on-Thames; Mr. Owen, Maidenhead; Messrs. Veitch & Sons, Chelsea; and especially to Mr. C. Harman Payne, and Mr. Alfred Salter. Where known, I have given the raiser's name, and where this was not obtainable have substituted the name of the grower by whom each variety was sent out. At the head of the raisers and introducers of those refined and exquisitely formed incurved varieties stands the time-honoured name of Salter, while among the more *négligé*, and now more generally popular Japanese, *Délaux* is credited with either raising or introducing more than one-third of the varieties on my list—surely a remarkable performance for any florist, however gifted.

It is an extremely difficult matter to describe correctly the colours of many Chrysanthemums, for they possess tints not

met with in any other flowers with which I am acquainted. The yellows, it is true, are nearly always bright and clear in tone, but as soon as we come to the different shades of red the matter becomes far less easy. In the trade catalogues we meet with "bright crimsons," "rich crimsons," and "velvety crimsons," to say nothing of "violets," "mauves," "pinks," and even "scarlets," colours which naturally suggest far more vivid tints than they are intended to represent. Even in my own descriptions, which have been obtained from the National Chrysanthemum Society's Catalogue, and introduced here in order to enable those unacquainted with the different varieties to make a selection of the best sorts in different shades of colour, I must request the reader to remember that whenever the words, rose, pink, crimson, purple, mauve, &c., are used, to picture to themselves, in most cases, only dull and very subdued tints of such colours.

Before finally quitting these incurved and Japanese varieties, it may be well to mention that I am informed that both Lady Harding and Mrs. Sharp are in all old Chrysanthemum lists spelt without the final e, usually found appended to their names in most modern catalogues.

If arranged in the same way as in the above lists, the reflexed varieties would dispose themselves in the following order—viz.: 1, Cloth of Gold; 2, Golden Christine; 3, Crimson King; 4, Peach Christine; 5, Phidias; 6, Pink Christine; 7, White Christine; 8, Cullingfordi; and 9, Felicity. Of the new Japanese Anemones, the most frequently shown were—1, Sœur Dorothee Souille; 2, Fabian de Mediana (Fabias de Maderanaz); and 3, Madame Cabrol. I should have liked to have inserted here the best of the Pompons, but these were staged so far back that I was unable to obtain a complete list of the varieties exhibited.—E. M., *Berkhamsted*.

#### INCURVED VARIETIES.

Position in Analysis	Number of times Shown.	Name.	Date of Introduction	Raiser's or Introducer's Name.	Colour.	Remarks.
1	57	Empress of India .....	1859	Laing	Pure white	Sent out originally as Lady St. Clair.
2	49	Golden Empress of India.....	1875	Loader	Pale yellow	Sport from Empress of India.
3	42	John Salter .....	1866	Salter	Cinnamon, orange centre	Synonymous with Mr. Howe.
3	42	Lord Alcester .....	1882	Salter	Pale primrose	Sent out originally as Princess Imperial.
4	38	Queen of England .....	1849	Salter	Blush	
5	34	Mr. Bunn .....	1879	Bunn	Rich golden yellow	Sport from Golden Beverley.
6	29	Jeanne d'Arc .....	1881	Lacroix	Blush, tipped rose-purple	Synonymous with Mad. Madeleine Tezier.
6	29	Princess of Wales .....	1864	Davis	Blush, tinted rose	Synonymous with Princess Alexandra.
7	28	Lord Wolseley.....	1882	Orchard	Bronze-red	Sport from Prince Alfred.
8	27	Prince Alfred .....	1864	Davis	Carmin-purple	
9	24	Alfred Salter .....	1856	Salter	Pink	Sport from Queen of England.
9	24	Nil Desperandum .....	1862	Smith	Dark orange red	
10	23	Refulgens.....	1871	Salter	Purple-maroon	
11	22	Lady Harding .....	1861	Clark	Delicate rose	
12	21	Hero of Stoke Newington.....	1871	Forsyth	Pink	Sport from Princess of Teck.
12	21	Mrs. Heale .....	1866	Heale	White	Sport from Princess of Wales.
12	21	Prince of Wales .....	1865	Davis	Maroon-purple	
13	20	Jardin des Plantes .....	1860	—	Rich golden yellow	
13	20	Mrs. W. Shipman .....	1877	Shipman	Fawn	
14	19	Princess of Teck .....	1868	Pethers	White	Synonymous with Princess Mary.
15	17	Barbara .....	1872	Salter	Bright orange, amber centre	Raised in Guernsey.
16	15	Cherub .....	1862	Smith	Golden amber	
17	13	Golden Queen of England ...	1859	Salter	Canary	Sport from Queen of England.
18	12	George Glenny .....	1870	Waters	Primrose	Sport from Mrs. G. Rundle.
18	12	Golden Eagle .....	1863	Downton	Dark orange	
18	12	White Venus .....	1872	Shrimpton	Pearl white	Sport from Venus.
19	11	Emily Dale .....	1872	Dale	Pale straw	Sport from Golden Queen of England.
19	11	Princess Beatrice .....	1868	Wyness	Rose pink	Raised from seed at Buckingham Palace.
20	9	Empress Eugénie .....	1866	Pethers	Rose lilac	Sent out by Salter.
21	8	Mrs. G. Rundle .....	1867	Rundle	Pure white	Raised from seed by Rundle.
21	8	Venus .....	1865	Salter	Peach	
22	7	Beverley .....	1863	Smith	Cream-white	
22	7	Lady Slade .....	1864	Smith	Lilac-pink	
23	5	Abbé Passaglia .....	1863	Smith	Bronze-amber	
23	5	Golden Beverley.....	1866	Butcher	Pale golden yellow	Sent out by Salter.
23	5	Mabel Ward.....	1881	Martin	Buff	Sport from Eve.
23	5	Mr. Brunlees .....	1865	Smith	Indian red, tipped gold	
23	5	Mrs. Dixon .....	1874	Dixon	Rich golden yellow	Sent out originally as Golden Geo. Glenny.
24	4	Baron Beust .....	1868	Pethers	Chestnut-red	Sent out by Salter.
24	4	Bronze Jardin des Plantes ...	1868	Garaway	Bronze	Sport from Jardin des Plantes.
24	4	Eve .....	1865	Smith	Sulphur white	
24	4	Mrs. Sharp .....	1868	Sharp	Rose-pink	Synonymous with Incognito.
24	4	Rev. C. Boyes .....	1877	F. T. Davis	Crimson	
24	4	St. Patrick .....	1864	Davis	Bronze-red	
24	4	White Globe .....	1858	Salter	Pearl white	Raised in Guernsey.

#### JAPANESE VARIETIES.

Position in Analysis.	Number of Times shown	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.	Remarks.
1	41	Madame C. Audiguier .....	1879	Marrouch	Deep mauve	
2	38	Jeanne Délaux .....	1882	Délaux	Dark violet brown	Synonymous with J. Délaux and F. A. Davis
3	34	Fair Maid of Guernsey.....	1871	Carey	Pure white	
3	34	Madlle. Lacroix .....	1880	Lacroix	Sulphur white	
4	28	Criterion .....	1868	Salter	Amber	
5	23	Comte de Germiny.....	1881	Veitch	Nank en, striped crimson	Imported from Japan.

## JAPANESE VARIETIES (Continued).

Position in Analysis.	Number of times shown.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.	Remarks.
5	23	Madame B. Rendatler .....	1877	Délaux	Orange, shading to yellow	Synonymous with Curiosity.
6	22	Thunberg .....	1881	Veitch	Pale gold yellow	Imported from Japan.
7	21	Elaine .....	1871	Carey	Pure white	Sent out by Dixon.
8	20	Agréments de la Nature .....	1881	Délaux	Golden yellow, shaded brown	
8	20	Peter the Great .....	1876	Carey	Lemon yellow	
9	18	Soleil Levant .....	1824	—	Pale yellow	Same as Tasselled Yellow (China).
10	17	Marguerite Marrouch .....	1878	Marrouch	Crimson, edged gold	
10	17	Monsieur Ardène .....	1878	Lacroix	Rose-lilac	
10	17	Monsieur Astorg .....	1883	Délaux	White, rose-violet centre	
11	15	Hiver Fleuri .....	1879	Délaux	Cream white, tinted rose	
12	14	Meg Merrilies .....	1870	Salter	Sulphur white	
12	14	Monsieur Tarin .....	1883	Délaux	Silvery violet rose	
12	14	Triomphe du Nord .....	1857	—	Crimson-maroon	
13	13	Fanny Boucharlal .....	1879	Boucharlal	White, with pink tinge	
13	13	Japonais .....	1878	Délaux	Bronze yellow	
13	13	Val d'Andorre .....	1880	Marrouch	Dull red and orange	
14	12	Dr. Macary .....	1878	Délaux	Rose, tinted white	
14	12	L'Incomparable .....	1884	Délaux	Bronze, spotted crimson	
14	12	Monsieur Délaux .....	1877	Délaux	Crimson, with yellow centre	
15	11	Alba Plena .....	—	—	Delicate creamy white	
15	11	Boule d'Or .....	1882	Bernard	Yellow, tipped bronze	
15	11	Triomphe de la Rue des Châlets .....	1876	Pertuzés	Salmon-red	
16	9	Madame de Sévin .....	1884	Délaux	Amaranth, lilac, and white	
16	9	Monsieur Henri Jacotot .....	1883	Délaux	Crimson, tipped gold	
16	9	John Laing .....	1884	Délaux	Crimson, brown-and-gold	
17	8	Baronne de Prailly .....	1868	Salter	Rose-blush	Imported from Japan.
17	8	Comtesse de Beauregard .....	1868	Salter	Light rose	Imported from Japan.
17	8	Flamme de Punch .....	1883	Délaux	Bright orange-red	Synonymous with Punch.
17	8	Margot .....	1883	Délaux	Rose-chamois	
17	8	Monsieur Brunet .....	1879	Lacroix	Lilac-mauve	
17	8	Rosea Superba .....	1883	Délaux	Rose-lilac, shaded chamois	
18	7	Belle Paule .....	1881	Marrouch	White, edged rose	
19	6	Red Gauntlet .....	1876	Carey	Dark crimson	
19	6	Sarnia .....	1876	Carey	White, shaded violet rose	
20	5	Baltimore .....	1878	Délaux	Rose-purple	
20	5	Cry Kang .....	1868	Salter	Rose-magenta	
20	5	Ethel .....	1871	—	Paper-white	
20	5	Golden Dragon .....	1867	Salter	Bright yellow	Imported from Japan.
20	5	James Salter .....	1869	Salter	Manve	
20	5	Monsieur Moussillac .....	1883	Délaux	Deep crimson-and-gold	
20	5	Parasol .....	1879	Lacroix	Brown-amber	
21	4	Albert de Nurios .....	1882	Délaux	Reddish-crimson	Synonymous with Albert.
21	4	Fernand Féral .....	1884	Délaux	Rose-mauve and cream.	
21	4	Madlle. Moulise .....	1878	Lacroix	Sulphur-white	
21	4	Mrs. Mahood .....	1882	Mahood	Cream-white	
21	4	Mary Major .....	1882	Salter	Pale rose, shading to white	
21	4	Monsieur A. Vilmorin .....	1885	Délaux	Orange-crimson, shaded gold	
21	4	Oracle .....	1870	Salter	Rose-purple	
21	4	Source d'Or .....	1882	Délaux	Orange, shaded gold	
11	4	Sultan .....	1870	Salter	Rose-purple	

## ASPARAGUS CULTURE.

DETERMINED some time since to make a trial of the different varieties of Asparagus, I procured seed of all the varieties named by seedsmen, and tried them in the same soil and under the same mode of cultivation. The seed was sown in rows a foot apart early in April, and the seedlings were transplanted when a year old in rows 3 feet apart and 1 foot asunder in the rows on ground that had previously been trenched and well manured. The planting was effected by taking out a sloping trench on both sides the stretched line, and the plants being placed astride the ridge, and the roots spread out straight and evenly in the furrows, the sharp ridge being knocked off so as to form a seat for the plants, and when the soil was returned the crowns were covered with 2 inches of soil. They were planted when beginning to push fresh shoots, and the ground over the rows was mulched with fresh farmyard manure. The rows were kept free from weeds, and the ground salted in spring and again about June, receiving the usual pricking and manuring in winter, and in other respects treated the same as Asparagus land usually is, with the difference that a good mulching of rough manure was given in early summer between the rows.

In the third year the difference between the varieties became strongly marked. The Early Giant Purple Argenteuil had much the larger spread of "grass," being double that of Connover's Colossal, and Giant or Battersea was also superior in quantity of grass to Colossal, which meant crowns and corresponding heads for cutting in spring. Late Giant Purple Argenteuil differs only from the Early Argenteuil in being a little later. The Early Giant Purple Argenteuil pushed heads ten days or a fortnight in advance of the other, and the heads were large, very many more in number,

and they were remarkable for bright purple tips, an evidence of high flavour. Connover's Colossal produced its heads sparingly though in succession over a lengthened period, but the Argenteuil seemed to give its heads in quicker succession, and similar remarks apply to the Late Argenteuil, the heads of these varieties being given more together. Giant afforded its smaller heads but in greater profusion and in better succession than Connover's Colossal, the latter having pale-coloured heads, and less highly flavoured. Of the Giant or Battersea there were two distinct types—one had pale-coloured heads, and the other much deeper purple, and whilst the former were rounded the other is decidedly pointed. These Giant Purple Argenteuils are evidently selections of Battersea, and Connover's is only an enlarged edition of the light-coloured form of Battersea, just as the latter itself developed into giant form from careful selections of the most highly cultivated indigenous plant.

The different forms of Asparagus are all unquestionably of one type, yet even in a bed of plants from seed of the common or English Asparagus we may note some marked by greater vigour, earlier in making growth, and in affording various degrees of colour in the heads, as well as dissimilarity in other respects. Selections may be made to represent at least four varieties from any batch of common seedling Asparagus, there being (1) pale-coloured and rounded heads, (2) purple-coloured and pointed heads, and both these admit of subdivision into early and late varieties. It is much the best plan to accept the higher forms of this most esteemed of spring vegetables, and which the seedsman and cultivator alike are benefited in selecting and continuing. "Business" will outlive any petty prejudices; there is no standing still in these days.

Never think of growing Asparagus in heavy soil with a view to

profit. It answers in private gardens to make heavy land light by the addition of opening materials, such as ashes, sand, ditch scourgings, road scrapings, old potting material, the *débris* of the rubbish heap, charred refuse, burnt clay, and the lime and other rubbish of an old building, with as much manure as you like; but this does not suit the market grower, as there is so much land of a light sandy nature that only needs enriching to grow excellent crops of Asparagus. Alluvial soils also suit Asparagus admirably, but in these the crowns are much more liable to decay than in sandy loams on a higher level, and the plants are not nearly so long-lived in the low as in the higher ground, for Asparagus seems to thrive best in a loose free soil through which water can percolate freely. Water stagnating causes sourness, the roots perish, the crowns decay, the soil is so cold that growth takes place late, and the results are most unsatisfactory.

Even in good soils Asparagus is spoilt by being grown too thick. I find the results much better when the rows are 3 feet apart than when they are 18 inches, though there is much to be said in favour of thicker planting when the object is to lift every alternate row in the third year for forcing, as well as in the resulting heads for cutting in the first few years of cropping, as it is easy to plant 18 inches asunder and clear out every other row after being cut hard for a couple of years by merely chopping off the crowns. I have not had sufficient experience of the wide planting to recommend its adoption, and the removal of every other row for forcing so injures the roots of the permanent plants as to militate considerably against the produce in the coming spring. Therefore plant Asparagus permanently (one or at most two years old) at their proper distance in the first instance, and a yard apart one way and 18 inches the other is not too much if large heads in quantity, bringing the best prices, are desired.—UTILITARIAN.

#### VICOMTESSE HERICART DE THURY STRAWBERRY.

HEREWITH I send you sample of the above Strawberry gathered from 5-inch pots started in heat in the middle of January. These small pots are carrying six to eight good fruits. We have others started in heat on the same date in 6-inch pots, but they will not be ripe for six or eight days, although grown under precisely the same treatment, which shows the advantage of root-confinement in small pots for very early work. We started our first batch middle of November, and gathered on March 18th. Everything considered, I think this old favourite Strawberry will hold its own against many of the newer sorts, several of which I have discarded after giving them repeated trials for early forcing.—J. H. GOODACRE.

[The fruits received are excellent alike in size, colour, and quality.]

#### STOKING—ANTHRACITE COAL.

THE excellent articles upon stoking that have lately appeared in the Journal are worthy of careful attention from those who in course of their duties have to take responsibility for the proper attention to the heating appliances. Stoking is to many gardeners a cause of great annoyance, from those having charge of the fires neglecting to give to them that intelligent interest which is absolutely required. Temperatures in good-sized houses may be kept fairly regular by a thoughtless stoker who has his pipes now quite cool and the next burning hot, but such work will never give satisfaction, whilst in smaller-sized houses, which are now becoming the rule rather than exception as formerly, such practice is ruinous.

I have, in common with most gardeners, had considerable trouble on this account, and have tried many ways to meet it. Gardeners do not care to be always grumbling, nor do they care to send such men away with the indorsement on their characters that they cannot be trusted with the charge of forcing houses. Gardeners also are often handicapped by having to work boilers of insufficient heating power, this being my experience at the present time. To meet this the best of fuel must be used, and too often a quick bright fire all the time, with little use for a hamper. In trying at various times to make the best use of the allowance for fuel, I have watched the market and nursery growers, and from the latter of these in first instance I had the hint to try anthracite coal. This I have been doing to my great satisfaction during the last five months, and have not before passed a winter so comfortably, from the night stoking point of view particularly since taking charge in my present situation.

The coal, if mixed at the rate of four to one with ordinary small coal, will give a fierce heat, last very long time with little attention, is clean and comfortable to work, making little dust and scarcely any ash or clinker; compared with a mixture of coke and coal I have before used, the two latter are scarcely a fourth part. I have intended for some time to bring the fuel before the attention of gardeners, as for such it will prove if fairly tried a very great boon. We bank up at ten o'clock and

have good fire and heat the following morning with little labour, which was far from the case before trying this fuel.

The cost in the first instance is higher than coke, but the coal lasts so much longer and gives off so much more heat that the cost comes about equal. Two barrowloads of coal will do the work of nearly four of coke. I use little ordinary coal with the anthracite to create a better draught, as the anthracite being smokeless with us requires the addition of flame to give sufficient draught to bring out the full heat. It never cakes, but burns clear and bright. I get my supply from a dealer in Swansea, who would do well to make it more fully known by advertising it.—A HEAD GARDENER.

#### RANGE OF PLANT HOUSES, Highbury, BIRMINGHAM.

HORTICULTURE is well supported in the neighbourhood of Birmingham, both the summer and autumn exhibitions being some of the best held in the provinces. This season a special effort is being made, and the Orchid Show to be held in the Botanic Gardens, Edgbaston, next month may be expected to prove one of the chief events of the year. The prizes are substantial, and there are several good collections of these popular plants in the district, from which numerous treasures will no doubt be contributed. Many visitors will be attracted to Birmingham, and those who wish to make a tour of the neighbourhood should include in their programme a journey to Highbury, Moseley, the residence of the Right Hon. J. Chamberlain, M.P., which is a few miles out and is conveniently reached by rail. Orchids have been made a specialty there for several years, and to provide better accommodation for these and other plants an extensive and well-fitted range of houses was erected for Mr. Chamberlain some time since by Mr. Henry Hope, horticultural builder, 55, Lionel Street, Birmingham. This is one of the most convenient and carefully considered range of houses devoted to plants that we have seen, and is constructed upon a plan similar to that generally adopted upon the Continent—namely, the houses are placed closely together at right angles with a corridor which connects them and permits the whole being inspected without once passing outside. The advantages of this plan can be duly appreciated in wet or cold weather, while in transferring the plants to or from the potting shed or to other houses they are not exposed to cold air, which so frequently checks them injuriously under ordinary systems. In a few trade and private establishments this principle is adopted, but it is by no means so general as it deserves to be, especially as such a corridor is useful in many ways, and can be rendered one of the most ornamental portions of the glass houses. For many cool Orchids they are admirably adapted, as can be seen at St. Albans, where large numbers in baskets are suspended from the roof, and others on blocks cover the walls. In most private gardens they are, however, better employed for climbing plants, some of the most useful and showy being grown either in pots or planted out, and trained up the walls or to the rafters. A beautiful avenue is thus formed where a plentiful supply of flowers can be obtained during the greater part of the year, as narrow borders along each side may be utilised for miscellaneous flowering plants, either permanent occupants, or like bulbs and ordinary forced plants they can be renewed as required and a continuous display maintained.

In the ground plan (fig. 47), which is drawn to a scale of 32 feet to an inch, the form of this range can be readily seen, and a few notes upon the principal occupants of the houses will convey some idea of the extent of the collection. The range runs east and west; the front, the right-hand side in the sketch, facing south, and is connected with the mansion at (1), which opens into a handsome conservatory (2), paved with Minton tiles and well furnished with Palms, Ferns, Dracenas, and miscellaneous decorative foliage and flowering plants. Adjoining this, on the left (3), is the stovehouse and a pair of Climax boilers, which heat the whole of the range besides three vineries, the same number of Peach houses, and 100 feet of pits that are not shown in the plan. The next house (4) is the fernery, 28 feet long by 20 feet wide, and devoted to a choice collection of useful Ferns, Adiantums being largely grown for cutting. From this house the corridor (20) commences, its length being 190 feet and width 10 feet, the houses opening from it on the right being each 32 feet long, but varying in width from 10 to 24 feet. The larger houses have a central stage with side shelves of slate and a path of Portland cement round, but the others have only a central path with shelves on each side. The stove (5) contains the usual flowering and foliage plants, the majority healthy specimens of moderate size, and evidently liking their position. The Orchid houses commence with No. 6, which is appropriated to the East Indian species and others requiring similar treatment. Dendrobiums constitute an important part of the stock of this house, D. Wardianum being particularly well-grown in pots and in pans suspended from the roof, the growths made last year being from 3 to 4 feet long and very stout. D. superbiens, which some find difficult to grow, seems to succeed there, the pseudo-bulbs being 2 feet long in some cases, and as well developed as could be wished; they are grown in pans and freely exposed to the sun, a system which Mr. B. S. Williams has adopted at Upper Holloway with great success. D. Dalhousieanum is represented by an extremely fine specimen, having ten pseudo-bulbs with twenty racemes of ten or a dozen flowers each. Cyrtopodiums are in capital condition, C. niveum being a great favourite and thriving admirably. C. Lowi, C. Spicerianum, and C. Stonei are similarly good. The Cattleya house (7) is filled with Lælias and Cattleyas of all the best forms, together with some Vandas, which the gardener, Mr. Cooper, has found thrive better in the temperature of that house than in the warmer structure where

they were previously grown. He says they make much stronger roots and leaves, do not lose their foliage so readily, and flower much more freely in the cooler house. That pest the *Cattleya fly* has given trouble in the house named, and it has only been by cutting away all young growths

Fig. 47.—Plant house at Highbury, Birmingham.

showing any signs of containing the grub that it has been exterminated. Happily this has been accomplished, and the plants are fast recovering from the injury they received. On one occasion as many as a thousand growths were cut away infested with this pest, which is one of the worst Orchid growers have to contend with wherever it gets established. Some

of the best specimen *Cattleyas* are *C. Mendeli* with eleven and sixteen growths, *C. Mossiae* with eighteen growths, *C. Trianae* with six to eight growths, *C. Percivaliana*, *C. gigas*, *C. exoniensis*, and many others all equally healthy. *Laelias purpurata* and *elegans* with their white varieties are thoroughly at home, one example of *L. purpurata* having had thirty-nine flowers, and they are showing well now. *Cattleyas Dowiana* and *C. Sanderiana* are in good health, the former suspended from the roof in pans.

Two smaller houses are next reached, one (8) being in two divisions, chiefly for table plants at the warm end, *Calanthes* and *Phalaenopses* at the other. The adjoining one of similar size (9) is the Orchid show house, whither the best of the Orchids in flower are brought from the other houses and tastefully arranged with Ferns, and as the end of the house facing the door is fitted with a mirror a very pleasing effect is produced in the same way as Mr. Bull arranges his plants at Chelsea every year. Some of the most notable plants flowering at the present time are as follows:—*Cattleya Trianae*, *C. Trianae Corningi*, *Cymbidium Lowi*, *Calanthe Regneri*, *C. Turneri*, *C. vestita oculata gigantea*, *Laelia anceps*, *L. albila*, *Lycaste Skinneri*, *Dendrobium Wardianum*, *D. nobile*, *D. primulinum*, *D. Cambridgeanum*, *D. Pierardi*, *D. superbiens*, *Cypripedium niveum*, *C. Lowi*, *C. Stonei*, *Odontoglossum Alexandrae*, *O. Pescatorei*, *O. maculatum*, *O. Rossi majus*, *Oncidium crispum*, and *Cymbidium eburneum*. The large houses (10 and 11) are occupied with Azaleas, Camellias, and greenhouse *Rhododendrons*, of which some fine trained specimens are grown, as well as smaller useful examples. Houses 12, 13, and 14 are devoted to *Pelargoniums*, *Cinerarias*, *Adiantums* and miscellaneous stove plants. A few Orchids are grown in Nos. 15 and 16, the latter containing some handsome specimens of *Laelia anceps*, *Cypripedium Schlimi*, *Coelogyne cristata*, *Odontoglossums vexillarium* and *Phalaenopsis*. The last house of the range (17) is chiefly employed for *Primulas* in winter. On the opposite side of the corridor is a convenient north house, 64 feet long and 10 feet wide, where the *Odontoglossums*, mainly *O. Alexandrae*, are grown and now throwing up a great number of spikes. *Masdevallias* are also grown in large numbers, representing the best species and varieties, comprising a good proportion of *M. Harryana*, *M. Veitchi*, and others. The potting-shed (19) is heated and fitted with every convenience, completing this very compact and excellent range.

Mr. Cooper has proved the advantages of free ventilation for all the Orchids under his charge, and the system adopted at Highbury is a good one, especially where the houses are in blocks, like they are there. The air is conveyed up each side of the house in channels, and can be admitted at pleasure immediately under the pipes, so that it is warmed before it comes in contact with the plants. By this means constant ventilation can be provided whenever the weather is favourable, and during the season of growth air is admitted very freely at the top of the house as well, care being taken, however, to insure a good supply of moisture in the atmosphere. The other houses already incidentally referred to are occupied with Vines and Peaches, from which good crops of fruit are annually obtained, while the garden generally is neat and well kept.—L. CASTLE.

## HINTS ON ORCHID CULTURE.

(Continued from page 251.)

### SELECTIONS OF ORCHIDS.

THE number of genera of Orchids recognised in the latest authoritative work, Hooker and Benthams "Genera Plantarum," is 334, which comprise a total of about 5000 species. Of these probably 2000 are in cultivation, but very few collections comprise 1000 species, and the majority are confined to much smaller numbers, especially where quantities of one sort like *Odontoglossum Alexandrae* are grown. The variation in habit, floral form, and colours is very great, and in no generally cultivated family do we get such a remarkable range. The majority of Orchids are comparatively dwarf, and in some cases diminutive, as in the *Bulbophyllums*, the Australian *B. minutissimum*, and a Bornean species found by Dr. Beccari having pseudo-bulbs one-twelfth of an inch in length and breadth, and are the smallest Orchids known. From these we get many gradations to the stem-producing *Vandas* and *Vanillas*, and then by a great advance to *Erythorchis* or *Galeola*, which has bare scrambling stems sometimes exceeding 100 feet in length in its native habitats. The majority of cultivated Orchids produce pseudo-bulbs, and are either evergreen, as in the *Cattleyas* and *Odontoglossums*, or deciduous as in the *Calanthes*. The stem-bearing Orchids of the *Aerides* and *Vanda* type, with the leaves arranged in a two-ranked manner on each side of the stem, are all evergreen, as also are the non-pseudo-bulbous Orchids of the *Cypripedium* type, except where these have tuberous roots, when they are usually deciduous, as in the North American forms of that genus. These peculiarities of habit must be all taken as indications of the treatment required, and, as previously pointed out, the deciduous species should all have a good period of rest.

Some of the most useful genera to the cultivator are the following:—*Aerides*, *Saccolabium* and *Vanda*, mostly small flowers, soft tinted, in racemes, and fragrant; *Angraecum*, principally white or cream-coloured flowers, varying much in size, *A. sesquipedale* being the largest; *Calanthe*, rosy crimson and white, free useful plants; *Cattleyas* and *Laelias*, showy Orchids, with large flowers

representing rich and soft tints of crimson, with white and gold markings; *Cœlogyne cristata*, white with yellow blotch, very useful; *Cypripedium*, variously coloured, not bright tints except some of the *C. Sedeni* group, but free and useful; *Dendrobium*, a handsome genus with abundance of golden yellow tints, or crimson purple and white in combination; *Dendrochilum*, small flowers, but in *D. glumaceum* very fragrant; *Lycaste*, white and crimson, very durable; *Masdevallia*, free useful plants, white, crimson, scarlet, and orange; *Odontoglossum*, chiefly white or yellow with brown spots and markings; *Oncidium*, a large number with bright yellow flowers; and *Phalenopsis*, white and rosy crimson. These comprise the most effective Orchids, but there are many other small genera, including species of great beauty. The principal curiosities as regards floral structure are found in the genera *Bulbophyllum*, *Catasetum*, *Cynoches*, *Coryanthes*, *Gongora*, *Mormodes*, and *Restrepia*, which present some extraordinary forms. The following will give some idea of the number of species in the leading genera, a few of the largest or best known being selected:—*Epidendrum* 400, *Pleurothallis* 350, *Dendrobium* 300, *Oncidium* 250, *Stelis* 150, *Maxillaria* 100, *Spiranthes* 100, *Masdevallia* 100, *Eria* 80, *Odontoglossum* 80, *Cœlogyne* 50, *Cypripedium* 40, *Cattleya* and *Lælia* 20 each. There are sixty-one monotypic genera—that is, comprising only one species each, and there is a large number with less than a dozen each.

**WHITE-FLOWERED ORCHIDS.**—White varieties of several Orchids are now much in demand and realise high prices; while sometimes the ordinary type of the species may be only worth a few shillings, as in *Lycaste Skinneri*, the white variety *alba* is sold for as many guineas. Of the cheaper white-flowered Orchids, such as *Odontoglossum Alexandræ*, *Cœlogyne cristata*, and *Phalenopsis grandiflora*, many are now being grown for market, and, together with the coloured *Dendrobium nobile*, make a feature in the florists' windows in Covent Garden Market. The following is a selection of the best white-flowered Orchids:—*Aeranthus Leonis*, *Angræcums*, *Anguloa eburnea*, *Calanthe Turneri nivalis*, *Cattleya Dominiana alba*, *C. Percivaliana alba*, *C. Skinneri alba*, *Cœlogyne cristata alba*, *Cymbidium eburneum*, *Cypripedium niveum*, *C. Sedeni candidulum*, *Dendrobium Deari* (very useful), *D. infundibulum*, *D. formosum*, *D. Jamesianum*, *Lælia albida*, *L. anceps alba*, and other varieties, *L. elegans alba*, *Lycaste Skinneri alba*, *L. Harrisoni alba*, *Masdevallia tovarensis*, *Odontoglossum Alexandræ*, *O. Pescatorei*, *O. pulchellum*, *O. Roezli album*, and *O. vexillarium album*. Some of these are not pure white, but there is very little colour in the majority, the *Lælias*, *Odontoglossums*, and *Cœlogyne* being valuable for cutting.

**ORANGE AND SCARLET-FLOWERED ORCHIDS.**—These tints are not very abundant, though shades of yellow are very numerous in the *Oncidiums* and *Dendrobiums*. The following are a dozen of the best of these tints, which are very effective, arranged with other lighter coloured flowers:—*Ada aurantiaca*, *Epidendrum vitellinum*, *E. aurantiacum*, *E. cinnabarinum*, *Lælia cinnabarina*, *L. flammea*, *L. harpophylla*, *Masdevallia coccinea*, *M. ignea*, *M. Veitchiana*, *Renanthera coccinea*, and *Sophranitis grandiflora*.

#### ORCHIDS FOR EVERY MONTH.

A supply of Orchid flowers can be easily obtained throughout the year; some like *Odontoglossum Alexandræ*, producing its blooms at all seasons, others like *Lycaste Skinneri*, last for a considerable time, and others are almost constantly in flower from the succession of blooms they bear. Orchids are by no means constant in their time of flowering, but the great majority of flowers are produced from March to midsummer, some of the *Lælias*, *Calanthes*, and others yielding an autumn and winter display. The following list by Mr. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, is a record of the times of flowering as observed in that establishment, where large numbers of species are grown. It will be understood that the months under which the plants are arranged are those in which the flowers expanded, and that some were consequently extended into the next or perhaps the following months. Though the periods named cannot be taken as fixed, they will serve to indicate what may be expected to flower at the principal seasons.

**JANUARY.**—*Cypripedium insigne* and varieties, *C. venustum*, *C. Boxallii*, *Cœlogyne cristata*, *C. sparsa*, *C. speciosa*, *Dendrobium Ainsworthii*, *D. crassinode*, *D. Devonianum*, *D. nobile*, *D. revolutum*, *D. primulinum*, *D. speciosum*, *D. Wardianum*, *Dendrochilum uncatum*, *Lælia albida*, *L. anceps*, *L. elegans*, *L. superbiens*, *Masdevallia ignea*, *M. Estradæ*, *M. Normani*, *M. polysticta*, *M. triangularis*, *Maxillaria aromatica*, *M. cruenta*, *Odontoglossum Alexandræ*, *O. cariniferum*, *O. maculatum*, *O. pulchellum*, *O. Rossi majus*, *Oncidium Forbesi*, *O. flexuosum*, *O. ornithorhynchum*, *O. serratum*, *O. varicosum*, *Phajus grandifolius*, *Phaëuopsis amabilis*, *P. grandiflora*, *P. Sanderiana*, *P. Schilleriana*, *Pilumna fragrans*, *Sophranitis grandiflora*, *Zygopetalum Mackayi*.

**FEBRUARY.**—*Ada aurantiaca*, *Brassavola glauca*, *Calanthe Regneri*, *Cattleya amethystoglossa*, *C. bultosa*, *C. Percivaliana*, *C. Trianae*, *C. chocoensis*, *Cœlogyne flaccida*, *Comparettia falcata*, *C. macropleuron*, *Dendrobium aggregatum majus*, *D. heterocarpum*, *D. luteolum*, *D. infundibulum*, *Epidendrum crassifolium*, *E. erectum*, *Helcia sanguinolenta*, *Odontoglossum*

*Pescatorei*, *O. radiatum*, *O. odoratum*, *O. triumphans*, *Oncidium cornigerum*, *O. Jonesianum*, *O. O'Brienianum*, *Lælia harpophylla*, *Lycaste Skinneri*, *Vanda cœrulescens*, *Phalenopsis Stuartiana*.

**MARCH.**—*Angræcum citratum*, *A. Ellisi*, *A. falcatum*, *Cattleya citrina*, *C. Lawrenceana*, *Cœlogyne ocellata*, *C. hololeuca*, *Chysis aurea*, *C. bractescens*, *Cypripedium argus*, *C. barbatum*, *C. ciliolare*, *C. hirsutissimum*, *C. Sedeni*, *C. villosum*, *Cyrtopodium Andersoni*, *C. Saintlegerianum*, *Dendrobium barbatulum*, *D. Jenkinsi*, *D. primulinum giganteum*, *D. fimbriatum oculatum*, *D. superbiens*, *D. Freemani*, *D. Pierardi*, *Epidendrum sceptrum*, *Lycaste plana*, *Odontoglossum Halli*, *O. Oerstedii*, *O. Phalenopsis*, *O. Roezli*, *O. cordatum*, *Oncidium cucullatum*, *O. Cavendishianum*, *O. unguiculatum*, *Phalenopsis Boxalli*, *Vanda tricolor*, *Zygopetalum crinitum*.

**APRIL.**—*Aerides Leeanum*, *Acicula Humboldtii*, *Arpophyllum giganteum*, *Brassia Kelliana*, *B. verrucosa*, *Cattleya Mendeli*, *C. intermedia*, *C. Skinneri*, *Colax jugosus*, *Cymbidium eburneum*, *Dendrobium Cambridgeanum*, *D. thyrsiflorum*, *D. densiflorum*, *D. secundum*, *Epidendrum alatum*, *E. vitellinum majas*, *E. xanthinum*, *E. fragrans*, *Masdevallia Harryana*, *M. Lindeni*, *M. Shuttleworthi*, *M. Chimæra*, *Meospinidium sanguineum*, *Odontoglossum cirrhosum*, *O. Cervantesi*, *O. vexillarium*, *O. citrosium*, *Oncidium concolor*, *O. Marshalli*, *O. longifolium*, *O. fuscatum*, *Leptotes bicolor*, *Lycaste fulvescens*, *L. Dowiana*, *L. candida*, *L. Skinneri*, *Phalenopsis Manni*, *P. Ludde-manniana*, *Saccolabium guttatum*, *Vanda teres*.

**MAY.**—*Camarotis purpurea*, *Aerides Fieldingi*, *Cirrhaea viridi-purpurea*, *Cœlogyne pandurata*, *Bulbophyllum Lobbi*, *Cattleya Aclaudiae*, *C. crispa*, *C. Mossiae*, *Cymbidium aloefolium*, *C. Lowianum*, *Cypripedium caudatum*, *C. Hookeri*, *C. Lawrenceanum*, *C. Lowii*, *C. Pearcei*, *C. Stoneanum*, *Dendrobium chrysanthum*, *D. albo-sanguineum*, *D. Falconeri*, *D. japonicum*, *D. moschatum*, *D. chrysotoxum*, *D. lituiflorum*, *D. Parishii*, *D. Lowi*, *D. macrophyllum*, *D. suavisimum*, *D. transparens*, *Epidendrum fragrans*, *E. macrochilum*, *Galeandra Devoniana*, *G. nivea*, *Huntleya violacea*, *Leptotes bicolor*, *Masdevallia amabilis*, *M. Houtteana*, *M. Wagneriana*, *M. Veitchiana*, *Maxillaria Harrisoni*, *Lælia purpurata*, *Odontoglossum cordatum*, *O. Halli*, *O. hastilatum*, *Palumbina candida*, *Saccolabium Blumei*, *S. curvifolium*, *Vanda Denisoniana*, *V. Batemannii*.

**JUNE.**—*Aerides Ballantianum*, *A. crispum*, *A. crassifolium*, *A. Fieldingi*, *A. Lobbi*, *A. odoratum*, *Brassia maculata*, *Anguloa Clowesii*, *Dendrobium Bensoniæ*, *D. infundibulum*, *Cattleya Warneri*, *C. Forbesii*, *Cypripedium barbatum nigrum*, *Govenia fasciata*, *Lycaste Deppei*, *Lælia crispa*, *Masdevallia Peristeria*, *Maxillaria grandiflora*, *Odontoglossum Lindleyanum*, *O. tripudians*, *O. Uro-Skinneri*, *O. sceptrum*, *Oncidium macranthum*, *O. reflexum*, *O. tricuspidatum*, *O. crispum*, *O. Papilio*, *O. Gardnerianum*, *O. luridum*, *O. Kramerii*, *O. dasystyle*, *O. prætextum*, *Stanhopea insignis*, *S. tigrina*, *S. Wardi*, *Thunia alba*, *T. Marshalli*, *T. Bensoniæ*, *Trichopilia coccinea*, *T. Galeottiana*.

**JULY.**—*Bollea cœlestis*, *Anguloa uniflora*, *Cattleya Eldorado*, *C. Gaskelliana*, *C. Leopoldi*, *C. superba splendens*, *Cymbidium pendulum*, *Cypripedium lævigatum*, *C. Veitchii*, *Dendrobium Farmeri*, *D. sanguinolentum*, *D. formosum giganteum*, *Epidendrum falcatum*, *E. radiatum*, *Grammatophyllum Ellisii*, *Masdevallia Trochilus*, *M. Normanii*, *Miltonia Regnelli*, *Odontoglossum Insleayi*, *O. Schleiperianum*, *O. constrictum*, *Oncidium bicolor*, *O. leucochilum*, *O. Lanceanum*, *O. incurvum*, *O. ampliatum*, *Phalenopsis rosea*, *P. violacea*, *Promenæa stapelioides*, *Sobralia macrantha*, *Vanda limbatula*, *Zygopetalum maxillare*.

**AUGUST.**—*Aerides quinquevulnera*, *Acropera Loddigesii*, *Brassavola nodosa*, *Cattleya Loddigesii*, *C. Wallisii*, *C. speciosissima*, *Cypripedium Harrisonianum*, *Dendrobium Deari*, *D. Tattonianum*, *D. triadenium*, *Disa grandiflora*, *Lycaste Cobbiana*, *L. Smeana*, *Masdevallia Davisii*, *Miltonia spectabilis*, *Odontoglossum bicktonense*, *O. grande*, *Oncidium tigrinum*, *R. strepia elegans*, *Sarcanthus Parishii*, *S. teretifolius*, *Trichopilia tortilis*, *Satyrium aureum*, *Stanhopea aurea*, *S. oculata*, *Warszewiczella Wendlandi*, *Zygopetalum Gantieri*.

**SEPTEMBER.**—*Cœlia macrostachya*, *Cattleya maxima*, *Cymbidium Mastersii*, *Burlingtonia granadensis*, *Dendrobium Ajax*, *D. crumenatum*, *D. leucophotum*, *Houlletia odoratissima*, *Lælia autumnalis*, *L. pumila*, *Maxillaria nigrescens*, *Miltonia Clowesii*, *Oncidium aurosum*, *O. Harrisoniæ*, *O. trulliferum*, *Phalenopsis violacea Schröderi*, *Rodriguezia planifolia*, *Vanda cœrulea*, *V. multiflora*.

**OCTOBER.**—*Burlingtonia decora*, *Cyrtorchilum maculatum*, *Cypripedium Spicerianum*, *Goodyera discolor*, *Houlletia chrysantha*, *Dendrobium bigibulum*, *Miltonia Weltoni*, *Lælia Dormaniana*, *L. præstans*, *L. Perrinii*, *L. marginata*, *Masdevallia tovarensis*, *Maxillaria picta*, *Odontoglossum Roezlii*, *Phalenopsis Esmeralda*, *P. Lowii*, *Pleione humilis*, *Sophranitis grandiflora*, *Trichocentrum albo-purpureum*, *Trichosma suavis*, *Zygopetalum Mackayi*.

**NOVEMBER.**—*Barkeria Barkeriola*, *Calanthe Veitchii*, *C. vestita*, *C. vestita lutea*, *Cattleya Holfordi*, *Cœlogyne assamica*, *C. falcata*, *Cymbidium giganteum*, *C. sinense*, *Cypripedium niveum*, *Dendrobium heterocarpum Philip-pinense*, *Epidendrum ciliare*, *Masdevallia oethoides*, *Maxillaria venusta*, *Miltonia Morelliana*, *Oncidium cheiroporum*, *Pleione lagenaria*, *Vanda Sanderiana*, *Zygopetalum crinitum cœruleum*.

**DECEMBER.**—*Angræcum Scottianum*, *A. sesquipedale*, *Barkeria Skinneri*, *Cattleya dolosa*, *Cypripedium concolor*, *Dendrobium nobile cœrulescens*, *D. Paxtoni*, *Lælia peduncularis*, *Odontoglossum gloriosum*, *O. Insleayi*, *Leopardinum*, *Pholidota imbricata*, *Sophranitis cernua*.

#### TWO HUNDRED CHEAP USEFUL ORCHIDS.

The appended list contains a selection of the cheapest Orchids suitable to form a good representative collection for an amateur commencing the culture of these plants, and it has been made as diversified as possible, excluding those most difficult of culture. They are arranged in the houses which suit them best during growth, but it will be understood that when in flower or resting the plants of the warm houses can be placed in cooler quarters. Where not otherwise stated the plants can be grown in pots in peat and sphagnum. Few are named for blocks, baskets being preferred for the reasons before explained.

**WARM HOUSE.**—*Aerides crassifolium* (basket), *crispum*, *odoratum*, *roseum*, *virens*; *Anæctochilus* (peat, sand, and sphagnum), *Lowi*,

setaceum; *Angræcum citratum*, sesquipedale; *Arundina bambusæ-folia* (peat and loam); *Cypripedium caudatum*, concolor (peat, sand, and lime), *Lawrencianum*, niveum, *Spicerianum*, *Stonei*, *superbiens*; *Cyrtopodium punctatum* (loam and manure); *Dendrobium aggregatum* (pot or block), *Ainsworthi*, *Dearei*, *formosum*, *luteolum*, *macrophyllum*, *thyrsofolium*, *Wardianum* (basket); *Dendrochilum filiforme*, *gluma-cium*; *Epidendrum bicornutum* (peat); *Galeandra Devoniana* (peat); *Huntleya violacea* (peat); *Ionopsis paniculata* (block); *Limatodes rosea* (peat, loam, and sand); *Mormodes pardinum* (peat); *Oncidium zebrinum*; *Phalænopsis* (pot, basket, or block) *amabilis*, *grandiflora*, *Luddemanniana*, *Schilleriana*; *Saccolabium* (basket), *ampullaceum*, *Blumei majus*, *curvifolium*, *giganteum*; *Scuticaria Steeli* (block); *Thunia alba*, *Bensoniæ*, *Marshalliana*; *Vanda teres*, *tricolor*, *Parishi*; *Vanilla aromatica*.

INTERMEDIATE HOUSE.—*Acineta Humboldti* (basket); *Aerides Fieldingi*, *japonicum*, *maculosum*; *Angræcum falcatum*; *Batemannia Melcagris*; *Brassavola Digbyana* (block); *Brassia Lanceana*, *verrucosa major*; *Broughtonia sanguinea* (block); *Burlingtonia* (basket, sphagnum) *candida*, *fragrans*; *Calanthe* (loam, leaf soil, and manure) *Masuca*, *Veitchi*, *vestita*; *Cattleya Acklandiæ* (block), *amethystoglossa*, *crispa*, *Dowiana* (basket), *Eldorado*, *gigas*, *guttata*, *Leopoldi*, *intermedia*, *labiata*, *Mendeli*, *Mossiæ*, *Skinneri*, *Trianae*, *Walkeriana* (C. bulbosa, block), *Warszewiczii*; *Chysis bractescens*; *Cœlogyne ocellata*; *Colax jugosus*; *Compæretia falcata* (block, sphagnum); *Cypripedium barbatum*, *Harrisonianum*, *Roezli*; *Dendrobium chrysanthum* (basket), *chrysotoxum* (peat), *crassinode* (basket, sphagnum), *densiflorum* (peat), *Devonianum* (basket, sphagnum), *Falconeri* (basket), *heterocarpum* (aureum), *nobile*, *Pierardi* (basket), *primulinum* (basket, sphagnum); *Epidendrum nemorale*; *Goodyera pubescens* (sphagnum); *Lælia cinnabarina*, *elegans*, *harpophylla*, *majalis*, *Perrini*, *purpurata*; *Leptotes bicolor* (peat); *Lycaste* (peat), *aromatica*, *Harrisoniæ*, *Skinneri*; *Miltonia* (peat), *cuneata*, *spectabilis*; *Odontoglossum Phalænopsis*, *Roezli*, *vexillarium*; *Oncidium ampliatum majus*, *flexuosum* (sphagnum), *Forbesi* (block), *Papilio* (block), *sphacelatum*; *Peristeria elata* (loam and leaf soil); *Phajus grandifolius* (loam, leaf soil, and manure); *Sobralia macrantha* (peat); *Uropedium Lindenii* (loam, sand, and peat); *Vanda cœrulea*; *Zygopetalum* (peat), *crinitum*, *Mackayi*.

COOL HOUSE.—*Ada aurantiaca*; *Anguloa* (peat), *Clowesi*, *uniflora*; *Arpophyllum giganteum* (peat); *Barkeria elegans* (block); *Bletia hyacinthina* (loam and leaf soil); *Cattleya citrina* (block); *Chysis aurea*; *Cœlogyne cristata*; *Cymbidium* (peat and loam) *eburneum*, *giganteum*; *Cypripedium insigne* *Maulei*, *Sedeni*, *venustum*, *villosum*; *Dendrobium Jamesianum*, *Disa grandiflora* (peat, sand, sphagnum, and manure); *Epidendrum vitellinum*; *Lælia acuminata*, *albida* (block), *anceps*, *autumnalis*, *Dayana*; *Masdevallia Davisii*, *Harryana*, *igneæ*, *Lindeni*, *polysticta*, *Shuttleworthi*, *Tovarensis*, *Veitchiana*; *Maxillaria grandiflora*, *venusta*; *Mesospinidium sanguineum*; *Nanodes Medusæ* (basket); *Odontoglossum Alexandræ* (crispum), *Cervantesi*, *cirrhum*, *citrosum*, *cordatum*, *gloriosum*, *grande*, *Halli*, *Insleayi*, *maculatum*, *odoratum*, *Oerstedii* (pot or block), *Pescatorei*, *pulchellum*, *Rossi* (basket or block), *triumphans*; *Oncidium cheiroporum*, *concolor*, *cucullatum*, *Marshallianum*, *ornithorhynchum*, *tigrinum*; *Pescatorea cerina*; *Pilumna fragrans*, *Pleione* (loam, peat, sphagnum, and sand), *humilis*, *lagenaria*, *maculata*, *Wallichiana*; *Promenæa citrina* (peat); *Sophronis grandiflora* (pot or basket); *Stanhopea* (basket, sphagnum), *aurea*, *grandiflora*, *tigrina*; *Trichopilia* (peat), *coccinea*, *suavis*; *Trichosma suavis* (peat).—AN AMATEUR.

#### THE WAKEFIELD PAXTON SOCIETY.

THE ninth annual dinner in connection with this useful and flourishing Society was held in the Society's meeting-room on Tuesday evening, the 23rd ult., and, as on previous occasions, the proceedings were of an exceedingly pleasant and satisfactory character. The esteemed President of the Society (Mr. T. Senior, solicitor) was in the chair, and he was supported by Alderman Reynolds (the Mayor) and other gentlemen. Mr. Herbert Chapman, the senior Hon. Sec., was prevented from attending owing to the death of his father. The company, which numbered seventy gentlemen, included the following deputation from kindred societies in neighbouring towns:—Mr. Simmonds and Mr. E. Austin, Sheffield and Hallamshire Gardeners' Society; Mr. W. K. Woodcock and Mr. Eadon, Sheffield Floral and Horticultural Society; Mr. T. Gartery and Mr. Winter, Rotherham Gardeners' Society; Mr. King and Mr. Levitt, Barnsley Paxton Society; Mr. W. Grix and Mr. G. Hemming, Leeds Gardeners' Benefit Society; and Mr. E. Elliott, Huddersfield Paxton Society. The room was tastefully decorated with evergreens, plants, and flowers.

The President explained the objects of the Society in an admirable speech, saying that the members, who are chiefly professional and amateur gardeners, meet to study and discuss everything in connection with botany and horticulture. The members met to impart knowledge to one another; to give and receive information on all matters connected with the science of horticulture. They had a very valuable adjunct in

the form of an excellent library of some 300 volumes, and they had been instrumental during the past year in forming the Yorkshire Association of Horticultural Societies, which was likely to effect a great deal of good. The members of the Paxton Society had met some forty-four times during the year to listen to essays, and he thought they had derived great pleasure from them. A window garden exhibition was held every year in connection with the Society, and he trusted that in future it would be better supported. He concluded by expressing a hope that the Society would continue to flourish, and that all who were then present might live to meet in that room on many similar occasions.

A special meeting of the members was held on Friday evening last. The Committee, by securing the services of an eminent botanist, had provided a rare treat for its members, and one which was much appreciated by a good audience. Leo H. Grindon, Esq., of Manchester, was the lecturer, and his subject "The Trees of Old England," proved very instructive and interesting. In the course of his lecture Mr. Grindon gave many clear illustrations of the various habits and peculiarities of one tree from another, and pointed out the best methods of distinguishing the several varieties by these peculiarities. The lecture was made popular by exclusion of technicalities and by the introduction of many racy remarks and appropriate selections of poetry, which frequently called forth hearty applause from the audience. A number of very fine etchings and engravings of the principal specimens of the various trees, and also dried specimens of foliage and bloom, were much admired and proved highly instructive. The best and most suitable trees for planting in towns was the principal topic for the ensuing discussion, and those most favoured for this purpose being the Plane, Lime, Elm, Hawthorn, and Alder.

The question of the Ash and Oak breaking into foliage irregularly, and thus indicating various changes in the weather, was very clearly answered by the lecturer stating that he knew of two Ashes and one Oak growing together, and that one of the Ashes was always in leaf before the Oak and the other one after it; and advising anyone who believed in the theory to mark twenty or thirty of each kind of tree and notice them for, say, three seasons; it would then be observed that most of the trees would adhere to the same order each year, and thus prove that the theory which many people believe as being "weather signs," were due to want of fair observation.

A hearty vote of thanks was accorded to Mr. Grindon on the motion of Mr. W. L. Skinner and seconded by Mr. T. Garnett.

#### VEGETATION IN BUCKINGHAMSHIRE.

THE season will be late in this vicinity. Vegetation has just commenced; but not a vestige of green can be seen for miles, neither Turnips or any of the Brassicas. A few Broccoli have escaped, but they are very small owing to the dry summer last year. Until within the past ten days in many places the country looks as if it had suffered from long drought, even the Blackberry bushes look as if scorched. On the 31st of March we had a very severe storm of hail accompanied by lightning and heavy peals of thunder. In sheltered gardens Crocuses, Aconites, and Daffodils are commencing to look gay. Polyanthes and Hepaticas also are flowering freely, while the hedgerows are beginning to be perfumed with Violets and Primroses, but in many the latter have not begun to flower yet, an almost unprecedented occurrence at the 1st of April. Ribes sanguineum is just showing colour; Gooseberry huds are beginning to expand, and Currants are hudding fast. Beyond these the trees and hedges seem dormant. Few birds have yet begun building, although the rooks made a start a fortnight ago, but operations seem at a standstill with them on account of wind and cold.—J. F.

#### WREATH MAKING.

THERE are many different ways of setting about this, but the simplest and most efficient method is to get a strong piece of wire, turn it to the size wanted, allowing for an overlap of at least 1½ inch at each end. Tie these overlapping pieces with ordinary bouquet wire, and a firm neat joint will be made. If the wire is too light to insure the stiffness necessary, make a double or treble coil, and fasten in three or four places in order to keep the wire together. The next step is to procure some coarse green moss, and the coarser is the better. Work the moss evenly round the wire, fixing it on with a strand of bouquet wire. When the moss has been firmly and neatly fixed press it gently so that the under and upper portion may be slightly flattened, and from 2 to 2½ inches across.

We come now to the best method of preparing the flowers; and it may be noted here that very indifferent flowers may be used, provided these are employed as a groundwork, and a few very choice blooms are worked in to stand out from these others; but in any case, whether poor flowers are used or the most choice alone, they all require to be prepared in the same manner—viz., by wiring. It may appear to those who have not much of this class of work to undertake that to wire flowers is a great waste of time, but it is not so. It saves time, whilst it also saves flowers, and it is the only method of procedure that gives the worker complete command of his material. The best kind of wire to use for stalks is the smallest size sold by all dealers in these articles in pound bundles cut to one length. For tying, the bright tying wire, sold on quarter-pound reels, is best. This is cut with a pair of scissors into 6-inch lengths, which is generally quite long enough for most flowers. No general rule can be laid down as to how flowers are to be wired, so much depends on the flowers themselves and the manner in which it is intended to use them. *Eucharis*, *Roses*, *Tulips*, *Carnations*, *Lily of the Valley*, greenhouse *Rhododendrons*, and *Camellias* are wired singly; *Violets* and *Snowdrops* in bunches, while

Marguerites, Clematis indivisa, and white Narcissus may either be wired and use singly or wired singly and arranged three to five on a common stalk. Double Pelargoniums may either be wired with one wire to a truss or the individual pips wired in clusters. These are merely examples of what may be done with certain flowers which are in season.

There is a method to be observed in attaching the flowers to the wire. Camellias, as is well known, are each pierced with two to three wires, in order to keep the petals intact. Roses are best pierced with a couple of wires, which keep the buds in shape and hinder the petals from unfolding. Carnations sometimes require to be wired in the same way. The wire in any case must be brought up as close as possible to the bloom. In some cases it may be pushed through the top of the flower, in others the wire may be run through the calyx and the top end bent down a little. In every case the flower is attached to the wire by twisting the fine wire round both. It does not require tying in any way. In making up bunches, say of Violets, only a few flowers must be attached to one wire, five or six being enough. The bunch can be of any size by tying as many of these small bunches as may be wanted on to one common stalk of wire. The Marguerites are tied singly to short pieces of wire and tied together to form a head of flowers in exactly the same way. Lily of the Valley is wired by placing a wire along the underside of the stalk and twisting the fine wire round both wire and stem. From 1 to 2 inches of stem is quite sufficient to have on any flower. The wired flowers must be kept separate by placing each in separate glasses or flower pots, and standing them in a row ready to the hand of the operator as he may want them. Where Arums are kept in flower the whole year round, these come in very well for wreath-making. The blooms must not be large, those 5 to 6 inches by 4 inches being of a suitable size. Arums are not wired, and must be fixed on the wreath before any other of the materials. After the Arums have been fixed, any of the flat flowers selected as a groundwork are then put in. These and all the other flowers are secured on the moss by piercing the moss with the wire, and after the flower has been drawn to its proper position from the underside the end of the wire is turned and thrust back into the moss. That is all the fastening any of the flowers require.

We like to have the flowers not crushing each other, but close enough together to make sure that nothing but flowers will be visible. Proceeding with the making of our wreath, after a sufficiently massive groundwork has been prepared, the blooms which are intended to give character to the wreath are fixed in according to taste and secured in the same way as the others. It is to be noted that blooms like Eucharis, Liliums, and single flowers of Rhododendrons should always be kept above the other flowers. The finer buds of Roses should also be used in the same way. Lilies of the Valley and Roman Hyacinths are, of course, kept well out from other flowers, while Marguerites, double Primulas, *Cœlogyne cristata*, and the Clematis above mentioned may also be employed to lighten the effect. When special flowers are wanted to be present in the wreath these may either be dotted among the others, or a few of them prominently massed together in three or four little clumps. Flowers of soft shades, as Violets, are best dotted all over the wreath. Bright flowers, as red Roses or Geraniums, show better in little masses. In going over the flowers to get each exactly into the position it shows to the best effect, the value of wired blooms will become evident, for every one is completely at the command of the operator to set as he pleases.

All that remains to be done now is to set the flowers in Fern fronds according to the taste of the maker. Gardeners work in the Ferns first and the flowers afterwards, but good wreath-makers add the Ferns as a setting after the flowers have been put on. No setting is better, or indeed equals, Maidenhair Fern for this purpose, stiff hardy-grown fronds being best. These do not require to be wired, but if the Fern is soft it is better a wire should be used. The fronds are fixed by gently pushing the flowers aside and pushing the stalk of the frond among them, so as to have a neat fringe of green round both the outside and inside of the ring. Pieces of Ferns are pushed in among the general body of flowers in the same way, but when extra good flowers are employed the fringe of green will be sufficient.

As to size, that again is a matter for taste, but it must be remembered that a small wreath of very good flowers is more desirable than a larger one which has to be composed of flowers of poor quality. The parcel post is largely used now for the transmission of wreaths, and the rules of the Post Office place a strict limit on the size to which wreaths can be made. A much finer cross can be sent by post. Crosses are made in the same way as wreaths, but country gardeners can make a very good base for the beginning of operations by constructing a wooden cross on which to tie the moss. Again, very neat floral bouquets, flat on one side and the top of flowers and Ferns, are very effective and well fitted to send per post. These bouquets are made entirely of wired material without the employment of moss for a foundation. Some stiff Fern is used to lie on the underside of the arrangement, any common Fern doing for the purpose. The flowers are tied on with a long strand of bright wire, and are arranged to taste. The usefulness of wired stems in these flat bouquets is most clearly seen, for by bending the wires at right angles, or indeed any angle, we get the bloom to face and position it is wanted. Maidenhair is worked in among the flowers as a setting. This is a cheap and effective method of employing flowers, especially when there is difficulty in finding enough flowers for all purposes.

Boxes for packing wreaths are made of a width just sufficient to hold the wreath to be sent; the depth is 4 inches. The four sides of the box are made of three-eighths of an inch deals, the bottom and lid of three-sixteenths of an inch deals. The box is tacked together with small wire nails. In packing a wreath it is sufficient to fill its open centre with wadding, as also the space at the four corners of the box, finishing with a

sheet of the same material between the wreath and the lid of the box; but it is found that by tying the wreath to the box, in addition to the packing, more satisfaction is given to the receiver. The simplest method of fixing the wreath to the box, is to bore four holes in the bottom of the box—two holes at opposite sides, and exactly beneath the wreath, and  $1\frac{1}{2}$  inch apart. A piece of strong string is run through each of the two holes, bringing the strings from the outside to the inside. When the wreath is laid in the box the two ends of each string is tied tightly down on the wreath, and renders it practically immovable. A ticket is sent on the top of the wadding, telling the person who unpacks the wreath to cut the string on the outside, and then lift out the wreath. We have for the past few years discontinued fastening lids of flower boxes by means of nails. The only fastening they require is to tie them tightly with stout string, to one end of which the address label is knotted. It only remains to warn those who have not experienced the close application of postal rules that it is only safe to keep wreaths amply within the dimensions as to size. We have experienced more than once the dissatisfaction of having to do our work over again, not because the size was beyond the limit, but for the reason of the weight being a little over the 7 lbs.—B.

### OLD v. NEW VARIETIES.

It is evident "A. L. G." practises what he preaches respecting novelties, judging from the list of vegetables enumerated in his last note (page 250). Without a doubt it is as "A. L. G." stated in a former number, a very simple affair, yet if it suits him and his employer it is all that is required. It is quite possible to introduce some novelty into the seed list without adding very materially to its cost by a man that sows the seeds with judgment, not as is too frequently seen in gardens, leaving a large quantity of plants in the seed bed after all are put out that are required, to be eventually wheeled to the rubbish heap, or dug in as useless. It is far better to sow smaller quantities. Under these circumstances I am able to obtain some novelty each year for my own pleasure, and generally speaking, to my employer's benefit.

"A. L. G." appears to assume that only gardeners of long standing can profitably grow new varieties, but if a man of however long standing were to adhere to such a restricted selection, he would never become a good judge of vegetables. It is as much a necessity for the young man to venture in novelties as for the most experienced, or how can he be expected to keep pace with the times? I do not question that the Aigburth Sprouts grown by "A. L. G." were good enough for exhibition, yet that would not tempt me to alter my opinion of the variety. If he could see that sort and Reading Exhibition side by side as grown here, he would, I think, decide in favour of the latter. The soil "A. L. G." has to deal with must be very different from what I have here, for if I had put out plants and watered twice only with such weather as experienced last summer, I am certain Brussels Sprouts would have been a very poor crop. I am asked by Mr. Easty to account for the name Gilbert's Universal, given in my previous note. It was a name given me in mistake by a neighbouring gardener, which doubtless he had confused with the Savoy sent out under that name.—S. B.

WE understand that at the next meeting of THE HORTICULTURAL CLUB the discussion at the conversazione will be opened by the Rev. C. Wolley Dod with a paper on "Daffodils," a subject which will at that time (April 13th) be much before the horticultural world.

— AT a meeting of the Fruit and Vegetable Committee of the ROYAL HORTICULTURAL SOCIETY, held at Chiswick on March 30th, Mr. George Bunyard in the chair—present Messrs. J. Burnett, W. Miller, S. Ford, G. T. Miles, and G. Norman—first-class certificates were awarded to the following varieties of Potatoes, as especially useful for late work:—Chiswick Favourite (Veitch), white round, rough skin heavy cropper, white flesh of good flavour. Bennett's Surprise (Bennett), white kidney, white flesh, good cropper, and of fine quality. King of Russets (Lye) large round, pink, with a somewhat deep eye, white flesh, rough skin, good cropper, and good quality.

— MESSRS. CROMPTON & FAWKES inform us that their slow-combustion boiler is on view at the BUILDINGS TRADES EXHIBITION now being held in the Agricultural Hall, Islington, but as tickets are not forwarded to us by the authorities we are unable to report on exhibits of interest to our readers at the Agricultural Hall Shows.

— WE are requested to state that the HEREFORD AND WEST OF ENGLAND ROSE SOCIETY'S SHOW will be held on the 9th July instead of the 8th, as advertised.

— MR. J. MUIR writes as follows on the PRESERVATION OF THE BRITISH FLORA:—"Many British plants may be scarce or extinct, but in my opinion few can have been exterminated, as suggested by Mr. Shirley Hibberd, p. 213, through prizes being offered for wild flowers at shows, and I am sorry to see any attempt being made to limit a very interesting department at many cottage and other horticultural shows. For several years past I have judged at many shows in Wales and England, besides being connected with the offering of wild flower prizes at Margam Show, and ninety-nine exhibits out of every hundred have simply been composed of cut flowers, Ferns, and Grasses, which could be secured without interfering with the roots. The extinction of plants must have been caused by another and perhaps a more learned class than the general exhibitors of wild flowers."

— THE most attractive trees in pleasure grounds in the neighbourhood of the metropolis at the present time are ALMONDS. They are densely covered with delicate blossoms, forming bouquets of silvery peach colour that are highly effective in contrast with the dark foliage of surrounding evergreens. They do not appear to have sustained any injury from the prolonged cold, but rather the reverse in retarding the blossoms, which have expanded under favourable conditions for their development.

— IT is questionable if the demand for CABBAGE PLANTS was ever so great in the south of England as at the present time. Throughout the long period of extremely cold weather there was little snow to protect them; and if, as has occasionally happened in previous years, snow in northerly districts has preserved them, good plants would find a ready sale if advertised.

— WRITING ON OUTDOOR MUSHROOM BEDS during the late severe weather, Mr. J. F. Barter observes, "The winter recently closed has been the most difficult I have experienced; and it has only been by the most careful attention that I have been able to gather regularly two and three times a week since the last week in October. Of course I did not expect such a crop as in ordinary winters, but the gatherings have averaged fully two-thirds of a full crop. I am afraid, however, that some amateurs and beginners in outdoor Mushroom culture have had a bad time, yet hope they will not be disheartened, but do as I have done many a time—try again till success is won."

— RELATIVE to successful Mushroom culture and the importance of STRONG SPAWN the experience of Mr. R. Holmes, The Gardens, Sister's House, Clapham Common, is worth recording. He forms a long bed 4 feet wide and a foot deep down the centre of a cool span-roofed vinery, adding to the length of the bed about 3 yards at intervals of three weeks. The last section but one was spawned six weeks ago with old spawn, and the crop is now just appearing; while the last addition in which strong new spawn was inserted three weeks afterwards is now covered with large fleshy Mushrooms. This example of rapid Mushroom production we have seen, and a more striking example of the influence of strong spawn has never come to our notice.

— WE have received the schedule of the EAST GLOUCESTERSHIRE ROSE SOCIETY. The Show is to be held at Moreton-in-the-Marsh on Tuesday, July 13th. Four classes are provided for nurserymen, and twice that number for amateurs, the leading prizes being £5, £3, and £2 respectively for thirty-six and twenty-four varieties. All the classes are open. The Right Hon. the Earl of Redesdale is President of the Society; and the Revs. J. W. Clarke, Leamington House, Moreton-in-the-Marsh and F. R. Burnside, Ivy House, Chipping Campden, Honorary Secretaries.

— A CORRESPONDENT, "W. M.," desires to know if DUC DE MAGENTA STRAWBERRY is a fine variety worthy of general culture. We have not grown it. Duc de Malakoff produces very large fruit. Growers of Duc de Magenta will oblige by communicating their experience with reference to this variety.

— PEACH BLOSSOMS AND POLLEN.—"T. F. R." remarks:—"During a long experience I have never seen the blossoms of the Peach, Nectarine, and Apricot so destitute of pollen as they are this season; the pollen cases have burst and are void. Your readers who have Peaches in bloom should carefully watch and transfer the pollen where it is abundant to the flowers which have none. In many cases the pistil even is wanting. It is very certain that without pollen there will be no fruit. The late frost in September may have injuriously affected the trees."

— "I AM disappointed in my DAFFODILS this season," says "A. M. B.," "and am glad to see the subject taken up in the Journal. Last year a small popular selection purchased from a distinguished firm did exceedingly well. This season the results will not be so good. Doubtless the strain upon the vitality of all vegetable life during the exceptionally severe and prolonged winter has proved damaging to many early spring garden favourites. Anemones have been sadly cut. Narcissi and Jonquills look weakly. In a week or so later I will, if permitted, chronicle more closely the few varieties of Daffodil I cultivate, with date of flowering this spring, and number and appearance of blooms."

— WE have received a copy of an official publication, entitled "A LIST OF SEEDS OF HARDY HERBACEOUS, ANNUAL, AND PERENNIAL PLANTS GROWN IN THE ROYAL GARDENS, KEW, 1885," and which we understand constitute the surplus stock intended for distribution to botanic and colonial gardens or in exchange. The list is a very full one, about 3000 species and varieties being enumerated and arranged in their natural orders, sub-orders, or tribes, as adopted in Hooker and Bentham's "Genera Plantarum," the genera being arranged alphabetically. The authorities for the names are given, together with the principal synonyms of many of the plants, and the native country. It is also stated whether the plants are annuals, biennials, or perennials, and thus forms a really useful catalogue for reference, especially as it appears to have been carefully compiled and revised. It can be obtained at the Royal Gardens, price 6d.

— MR. B. R. CANT of Colchester has sent us a basket of fruit of the noted D'ARCY OR ESSEX SPICE APPLE in wonderfully fine condition at this late period of the Apple season. They are plump, tender, rich in flavour, and everything that a dessert Apple of the first quality ought to be. Everybody ought to grow the Essex Spice.

— MR. J. DOUGLAS sends us the following note on the PRIMULA CONFERENCE AND NATIONAL AURICULA SOCIETY (SOUTHERN SECTION):—"Now that the weather has changed the prospect of a satisfactory exhibition of Primulas has been very much improved, and amateurs as well as professional growers are anxious to make it a great success. Everyone cannot make an exhibition of scores of distinct species; but many persons could exhibit a few, and any interesting or curious forms of the common Primrose would be acceptable. Notice of intention to exhibit and also of the nature of the exhibit should be sent to Mr. Barron, Royal Horticultural Society, South Kensington, S.W., at least a week before the Exhibition. The dates are April 20th and 21st. The National Auricula Exhibition is to be held at the same time on the 20th only; but the Primula Conference Committee would be glad if exhibitors would kindly leave their plants for the two days. The prizes offered for Auriculas are open to all competitors, except that there are classes for large and small growers. Entries must be sent to Mr. Barron as above. I shall be pleased to send schedules to intending exhibitors, and the Treasurer, Mr. H. A. Rolt, 170, Hartfield Road, New Wimbledon, informs me that the subscription list for this year is not yet complete. He will be greatly obliged if members will forward their subscriptions before the 20th inst."

— THE British Benevolent Society, Los Angeles, California, has issued a WARNING TO EMIGRANTS, from which it appears that there were so-called agents in London who received a bonus for every person they could induce to go out to "Antelope Valley" and adjacent places. They were told that they could purchase land there, and many parted with all they had, but upon arriving, found they had before them in "Antelope Valley" nothing but desert land. The Society had been called upon to help a large number of such unfortunate emigrants. There is also another system of fraud—namely, inducing youths to come over under the impression that, for a bonus varying from £20 to £70, they would be taught "fruit-farming, have a comfortable place, and receive a monthly salary." Advertisements appeared in London newspapers for this purpose, headed generally "To Gentlemen's Sons," "A Practical Farmer," &c. If persons are desirous of emigrating they can do so without paying a bonus to anyone; and, further, it should be known that it is useless for persons to go out unless they had at least £200 when they arrived. There was room for good domestic servants, but clerks, hook-keepers, and such-like there was no room for; and even mechanics were not in request. The only thing of use really was capital, and any having such would realise 10 per cent. per annum. The Society only desired to expose the false statements made by so-called agents.

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for MARCH, 1886:—Mean temperature of month, 38° 1'; maximum on the 21st, 63° 2'; minimum on the 7th, 8° 4'. Maximum in the sun on the 6th, 126° 6'; minimum on the grass on the 7th, 5° 4'. Extreme range, 54° 8'. Warmest day, 21st; mean temperature, 56° 1'. Coldest day, the 8th; mean temperature, 23° 0'. Mean temperature of air at 9 A.M., 38° 3'; mean temperature of soil 1 foot deep, 38° 6'. Nights below 32° in shade, sixteen; on grass, twenty-one. Total duration of sunshine in month, eighty-four hours, or twenty-three per cent. of possible duration. We had eight sunless days. Total rainfall, 2.35 inches. Rain fell on nineteen days. Average velocity of wind 11.1 miles per hour. Velocity exceeded 400 miles on six days. The month is remarkable for its heavy snowstorm on the 1st, and for the extreme cold from the 4th to 11th, and for the great contrast between the first and second halves of the month. The first fortnight is very similar to March 1883, but the mean temperature for the month is much higher than in that year, when the cold lasted all through the month. The rainfall is larger than in any year since 1877. We are greatly indebted to the snow for the protection it gave to many of our herbaceous plants, as we have not lost any. The Tea Rose bushes have suffered most; nearly all the wood is killed above the winter wrap of fern manure. Vegetation I think is twelve to twenty days later than last year.

— It is said that American brides are seeking all kinds of novelties for their WEDDING FLOWERS. A young bride wore white Sweet Pea blossoms combined with Orange flowers on her wedding day. Another bride wore Stephanotis in her hair and on her bodice, and carried a bouquet of Orange flowers, buds and fruit, with a mixture of Orchids. Some are substituting the wedding basket for the bridal bouquet. This basket is a round, flat satchel of Italian straw, which is swung on the arm by a satin sash. One side of the basket is festooned with pink Roses, and the other with Niphetos buds and Orange blossoms. The pink side is carried outside entering the church, and after the ceremony the white side is turned to be most conspicuous.

— WE have been favoured with the following note on THE FIRST FLOWER SHOW IN THE SCILLY ISLANDS. This was held Tuesday, 30th March, in the Infant School, St. Mary's, Scilly, under the auspices of the "Scilly Island Bulb and Flower Association;" President, T. Algernon Dorrien-Smith, Esq.; Secretary, Mr. Clement W. Mumford; Treasurer, Mr. William R. Mumford. The Exhibition to these islanders was one of unusual interest, the exhibits consisting mainly of well-grown Daffodils, of which the three groups were well represented. The competition for the numerous prizes was keen, and the inhabitants of the little town of St. Mary's took a lively interest in the Show. The weather being somewhat stormy the off islanders could not appear on the first and second day, but on Thursday the storm abated and a few additional exhibits came in and were awarded prizes according to merit. The exhibition of 1887 it is expected will be double or treble the size of 1886. One end of the room was occupied by Mr. T. A. Dorrien-Smith's exhibits, consisting of upwards of 160 varieties of Narcissus tastefully arranged on a groundwork of green moss. The prize of the day was £5, offered by the Earl of Mount Edgcumbe, for the best exhibit of marketable flowers of all descriptions, this was carried off by Mr. W. P. Mumford with fifty varieties of Daffodils. The same prize will be offered in 1887, and possibly others, as many who visit the islands and enjoy the hospitality of Mr. T. A. Dorrien-Smith may desire to follow the example of the Earl of Mount Edgcumbe. The Judges were Mr. Vallance, Tresco Abbey Gardens, and Mr. Peter Barr, London. In August there will be an exhibition of dry Narcissus bulbs grown on the Scilly Islands of the most marketable sorts, prize by T. Algernon Dorrien-Smith, Esq., £10, and again in 1887, the prize being £25.

## THE PRIMULAS.

(Continued from page 208.)

*P. PUMILA*, Kern. (*P. minima* × *daonensis*, Kern.).—This is well named *pumila*, as it is amongst the smallest Primroses we have in cultivation. It resembles *minima* more than the other parent, and, like the first, grows best when plenty of limestone is added to the soil. A partly shady spot sheltered from cold winds should be chosen, and it will be all the better on a steep slope or wall. The leaves are cuneate, with seven to nine large triangular teeth, edged with small sessile glands. Flower stem an inch or so in height, mostly two-flowered, and covered with soft

glandular hairs. Calyx campanulate, with teeth half as long as the tube. It flowers with us April and June. Found by Porta in 1873 in the Southern Tyrol at elevations of from 6000 to 7000 feet above sea level.

*P. PULCHRA*, Watt.—One of the new Himalayan Primulas lately collected by Watt in Jongri, and also by Sir J. D. Hooker at 12,000 and 14,000 feet in Lachen, Sikkim Himalaya. It seems to be a free flowerer, from two to ten flowers in a head, large, and of a deep purple colour. We have not seen it in cultivation yet.

*P. PUSILLA*, Wall.—This seems to be a variable species, the colour of the flowers ranging from rose to deep purple. It requires great care in management. In the seedling state they are so fragile that we prefer standing the pots in a saucer of water when dry rather than water them overhead. Raised mounds

Fig. 48.—*Primula sibirica*.

in a bog suit it best, as it suffers from excessive moisture. It grows about 6 inches in height, carrying a head of few flowers as large as *farinosa* or larger. Leaves on short stalks, rugose, narrow cuneate, with deeply dentate margins. Flowers June. Native of the Himalayas. Syn., *humilis*, Steud.

*P. REEDII* (Duby).—A new Himalayan species found last year by Dr. Duthie on wet rocks near Ralan Glacier. A large quantity of seed, we believe, has been distributed, and we hear of several successes in raising it. In habit and leafage it is not unlike *involucrata*, the flowers are, however, larger, white or pale sulphury yellow, apparently very free flowering.

*P. RETICULATA*, Wall.—This old Primrose has again been introduced to our gardens, but probably its ungraceful habit of growth will deter most cultivators from troubling with it. The flower stem is weak, a foot or more in length, with a few small yellow flowers. It requires much the same treatment as *sikkimensis*, which it resembles very much in habit and shape of leaf, the latter having much longer petioles. Native of the Himalayas. Flowering with us in June. Syn., *altissima*, Don; *speciosa*, Don.

*P. ROSEA*, Royle.—Among hardy spring-flowering Primroses

few better repay for any little extra attention than this little gem. Like all the others that require bog treatment, the leaves die during winter, leaving buds as in *involucrata*, but, unlike that species, *P. rosea* pushes up the flower stem first, many of the blooms being full open before the leaves show any sign of unfolding. During the growing season, and indeed all through the year, it requires plenty of water. Those found in the Kalu district eastward of Afghanistan were growing by the sides of streamlets, with their long white stringy roots far in the water. The best plants we have seen have been in swampy places fully exposed, besides its being a week or two earlier than in the ordinary border. It is very easily propagated, each bud or crowning forming a separate plant, readily detached from the others. It can also be raised from seed, which ripen freely in this country, and as it seems inclined to vary the latter may not be the least profitable means of increase. The flower stems vary from 2 to 6 inches in height, carrying about a dozen flowers in a close compact head. The flowers are about an inch in diameter, bright rosy carmine, and very attractive, and welcome so early in the year. Leaves ovate lanceolate, forming a dense tuft; margins sharply crenate, and revolute when young. It flowers in April. The variety *elegans* (*P. elegans*, *Duby*) we have not seen, but a deep coloured form called *grandiflora* is a distinct advance on the type. Native of Himalayas, &c., at from 10,000 to 12,000 feet above the sea level.

*P. RUSBYI*, *Hort. Ware*.—This, as far as we can judge, is a good species, although the name is not published in any works to which we have access. We first saw it flowering in the nurseries of Mr. T. S. Ware, Tottenham. It grows about 6 inches high, the scape carrying two or three large purple flowers, very handsome, and lasting a considerable time in bloom. Leaves ovate lanceolate, tapering into a narrow winged petiole 2 or 3 inches long. The serratures abrupt, small, and pointed. It flowers towards the end of summer, and we believe is of American origin. It is deciduous in winter, dying down to a bud. It seems to thrive best in a shady moist situation in a strong loamy soil, to which has been added plenty of small pieces of sandstone.

*P. SALISBURGENSIS*, *Floike*.—A small hybrid between *subglutinosa* × *minima*, *A. Kern*, and as far as leaf character goes taking more after the latter than the former parent. The leaves are cuneate in outline, the upper quarter of the blade set with from seven to nine largish triangular teeth, bottle green at the apex. The unpaired tooth in the middle of the leaf, unlike some of the other hybrids, is no longer than the two next ones, and the tip of the lower one on each side is somewhat blunted and shorter than the others. Scape not viscous, as in *glutinosa*. The bracts oblong, almost as broad as the calyx teeth, and shorter than the calyx tube. Flowers large for the size of the plant, dark peach red, the limb being longer than the corolla tube. Found in similar localities to the parents. It seems to thrive best with plenty of limestone broken small and pressed firmly round the roots. An eastern or western exposure, with plenty of water during March and April. It flowers in the latter month.

*P. SAPPHIRINA*, *Hk. fil* and *Thom*.—Is another of those gems from the Lachen valley, Sikkim Himalayas, where it is found at altitudes of from 13,000 to 15,000 feet above sea level. It has been lately introduced among others to our gardens, and, though perhaps a difficult, it will prove an interesting species. It is doubtful whether it will withstand the damp of our southern winters, but northern growers are sure to succeed with it as with the others. It rarely grows more than 1 or 2 inches high, the leaves forming small rosettes less than an inch in diameter. Petioles very short, with large deep teeth round the margins, with a sparse scattering of white hairs on the upper surface. The flowers few in a head, are less than half an inch in diameter, deeply bifid, of a bright or pale lilac blue. It flowers about the end of July or August. A shady corner seems the most suitable; rather dry during winter, but with plenty of water during the late spring months.

*P. SERRATIFOLIA*, *Gusmus*.—A hybrid between *minima* × *tyrolensis*, *Gusm.* which we have not yet seen in flower. It has much the habit of *P. minima*, leaves narrower, and less cuneate. The name is rather unfortunate, as M. Franchet has given the name *serratifolia* to one of the new Yun-nan Primroses. It is allied to *P. obtusifolia*, and a desirable garden plant.

*P. SIBIRICA*, *Jacq.*—There would be little difficulty in classing this species under *P. involucrata*, *Wall*—at least, in some of its various forms—and we believe that in a dried state they are difficult to distinguish, especially the varieties *kashmiriana* and *integerrima*, the latter from the Altai Mountains and the former from Kashmir (its southern limit), it being confined chiefly to Northern Europe, Asia, and Arctic America. The flowers, however, of all the forms we know are purplish rose-coloured, with

the exception of *integerrima*, which more nearly resembles *Munroi* in that respect. It grows freely on a low peaty bed, not too damp, and exposed to full sunshine. *P. sibirica* (fig. 48) forms a large rosette of oval or roundish oval leaves, with petioles unwinged about the length of the blade, free of powder, and quite glabrous on both sides, the margins entire or sparingly and unevenly crenate. The scape rises from 5 to 9 or 10 inches in height, carrying an umbel of about six drooping flowers, about an inch in diameter, purplish rose with a yellow eye, segments bifid and rounded; the involucre is exactly the same as *involucrata*, perhaps smaller, and the bracts less pointed. It flowers in April. Distributed from the Cambridge Botanic Gardens about 1830. Native of N. Siberia, &c. Syn., *intermedia*, *Ledeb.*; *rotundifolia*, *Pall*; *P. s.* var. *Finmarchica*, *Jacq.*

Fig. 49.—*Primula sikkimensis*.

of which *norvegica*, *Retz.*, is a synonym, is smaller in all its parts than the type, and not so useful as a garden plant. *P. s. integrifolia* we have not seen; *P. s. integerrima* is taller, more slender, and having smaller flowers; *P. s. kashmiriana* is also smaller, but more numerous flowered than the type.

*P. SIEBOLDII*, *Morr.*—Another name for the well-known *P. cortusoides* var. *amena*, so plentiful in gardens. The flowers are much larger than the type, various coloured, and having longer petioles. An excellent plant for either the rockery or mixed border, and may be increased to any extent by division of the roots in autumn. It forces very well, and may be had indoors a month or so earlier than it flowers outside. A group makes quite a feature in the greenhouse in late spring.

*P. SIKKIMENSIS*, *Hook.* (fig. 49).—Of all the Himalayan Primroses yet introduced to English gardens there are none to our thinking that exceed or perhaps even equal the present species when properly managed; for even this Primrose has its peculiarities, which must be suited as far as possible to the means at hand. A very prevalent belief amongst hardy plant growers is that many of this class of Primrose are either annual

or biennial, or, at least, are best treated as such; and, so far as our experience goes with *capitata*, *elliptica*, *Stuartii*, &c., it is the only means of procuring an unfailing crop of flowers annually. The plants rarely flower before the second year, and to keep up a supply it is necessary to make an annual sowing, so that the seedlings of this year will be depended on for the supply of flowers next year, and so on. *P. sikkimensis* ripens seed freely in our climate, and these sown when gathered soon germinate, and may be pricked out in boxes or rich beds in a shady situation and well watered through the summer months. In autumn, when the leaves have died down they can be shifted to their flowering quarters, lifting a good ball of soil with each plant. The bed in which they are to flower should be deep, rich peaty, and well shaded, and the result will abundantly repay all the trouble taken with the seedlings. The flowers being extremely handsome, emitting a delicious fragrance, which always succeeds in attracting one to them. The leaves all proceed from the root, from 8 inches to a foot long, obovate and oblong, and without meal on either side; nerves reticulated, prominent on the under side, dark green above, doubly and sharply serrated margins. The flower stem grows about a foot high, carrying an umbel of from ten to twenty or more large sulphury yellow sweetly scented flowers; involucre of from five to seven narrow sessile leaflets, half the length of the pedice's. "It inhabits wet boggy places at elevations of from 12,000 to 17,000 feet elevation at Lachen and Lachong," covering acres with a yellow carpet in May and June. It was first introduced by Sir J. D. Hooker about 1850. It flowers with us May and June, but may be forced earlier, and makes an excellent pot plant. It is perennial, but the best flowers are produced the second year after sowing.—D.

## THE INSECT ENEMIES OF OUR GARDEN CROPS.

### THE APPLE.

(Continued from page 72.)

EVEN as in the human body health is best maintained by the observance of natural laws, not by swallowing physic; so with fruit trees, and the Apple particularly, it is better to adopt such simple measures as are likely to prevent insect attacks than to apply remedies that may check or kill these foes in their various stages. It is in dark and crowded—perhaps also damp—orchards, that moths find themselves screened from observation while depositing eggs, and their broods of caterpillars are less likely to be seized by insect-eating birds; also if the grass, as sometimes happens in such orchards, is suffered to grow long, caterpillars blown off by the early summer gales escape hurt, and manage to crawl up the trunks to feed again. I doubt whether the fires of weeds or refuse which one sees about some orchards, kindled with a view of keeping off insects, do much good; the smoke is almost sure to be freely diluted by air, and moths hover at a distance, to return as the fire dies down. Owing to their peculiar habits, some moths that seek out the Apple are astir during the colder months of the year, when the fruit-grower entertains no apprehensions, and their progeny pierce the buds the moment they begin to expand. The cause of the mischief is often mistaken; thus a gardener picks off some damaged buds, and discovering ants about them, believes they have been the culprits, though, in fact, they have only come to suck the juices exuding from cuts made by caterpillars, which have probably migrated. Indeed, as I have myself noticed, ants favour us by dragging or carrying to their nests some young caterpillars, and they certainly do not breed or foster them, if they do their aphid's pets.

In some places on the Continent the caterpillar of the lunar spotted pinion (*Cosmia pyralina*) is common on the fruit trees, and particularly fond of the Apple. The moths fly in June or July, and the eggs appear to remain unhatched till the spring; the young caterpillars feed early and are of full size during May. These are of voracious habit, thick and fleshy, greenish, with a few paler spots and two dark lines. They are easily detected, but as yet the species has only been occasionally noticed in England, along the southern counties chiefly. The worst moth foe of our Apples is, I should say, the caterpillar of the small ermine moth (*Yponomeuta padella*)—that is, as far as the buds and leaves are concerned; though that promiscuous feeder, the caterpillar of the winter moth (*Chimatobia brumata*), is generally seen upon the Apple each year in varying numbers. About its habits it may suffice to remark that the green eggs are laid upon the bark of the trunk or branches by the wingless female, which crawls thither on emerging from the pupa at the end of the year. Flight to her being impossible, the late Edward Newman, when there occurred an outbreak of this pest amongst the cider orchards of the Midlands, wisely suggested that any method must be good by which she could be kept from climbing the trees. After experiment a composition of Stockholm tar and cart grease was proved to answer admirably daubed round the trunks in a ring, care being taken that the moth cannot get up by the aid of posts or loose branches. It does no hurt to the Apple laid on in November or December, but would do so when the weather was sufficiently warm to cause some absorption. It is, however, desirable to slit the bark next year, since the composition tightens it somewhat. Whatever eggs may be laid below this line they will not be likely to produce caterpillars that can reach to the buds; and if examination be made at night with a lantern many moths may be picked off. Such search should always be carried out during mild days of December

in the case of wall fruit trees where the insects cannot be thus prevented ascending. Some people indulge the expectation that a cold spring like the present may destroy the germs of life in the eggs of this and other species, but there is no ground for this idea; the emergence is delayed, that is all. Many caterpillars must be killed by the rains and winds of spring, though they keep themselves for a while concealed in the unexpanded buds, subsequently they feed exposed, save with the protection of a few silken threads. As upon any alarm they drop, it is easy to shake them off small trees or shrubs. This caterpillar is a slim looper of a whitish green or brownish hue, usually adult in May; it then descends to bury in the earth, and as it remains under ground several months by forking the soil and other measures quantities of the chrysalis can be destroyed.

From some cause, about which I cannot be positive, the caterpillars of the little ermine moth (*Yponomeuta padella*) were abroad in very small numbers during the season of 1885. Probably a large proportion of the early brood were killed off by the damp of the preceding winter, for it is their habit to emerge in autumn from the egg, remaining torpid until the approach of spring. It is a species liable to variation as to colour and dotting; one form, which is frequent upon the Apple, and has white fore wings, with a thick cocoon for the chrysalis; while the Hawthorn kind is nearly transparent, has received the name of *Y. malivorella*, and devour it they do indeed, through the influence of numbers, small as is their individual size. Beside the effects of their jaws there is the nuisance of their webs, which are drawn over the branches and shoots to enable them to travel readily, also perhaps affording a partial screen from birds, while the influence upon the growth of the tree is injurious, and it looks as if it were the drill ground of a party of spiders. The removal of these webs from Apple trees when they have reached this conspicuous stage can be managed, certainly, and all wandering caterpillars brushed or shaken to the earth, where they can be disposed of, but no fruit-tree grower should allow his trees to be thus preyed upon by the enemy; and at the period when the moths emerge it will be noticed that they crawl about the branches in a sluggish way, and they, too, may be hunted up and killed, since they fall should they be alarmed, so that they may be gathered and crushed.

The moth, fortunately, is conspicuous by its contrast of colour, and the caterpillar has also black spots, but upon a ground of dull yellow or buff and a black head, which shows more markedly when the creature is little. July is the month that brings forth the moths in most profusion; then the eggs are laid, so coated over with a glossy substance that we do not see them on the twigs, but they are artfully placed near blossom or leaf buds, generally near the former, so that they have food at hand when they rouse. No doubt it is advisable whenever the moths have been seen about to wash or syringe the trees well with any compound, or even a simple solution of soap just at the time the young brood are likely to be shifting from their winter retreats to attack the first growth. In France and Germany, where some years the Apples over many miles of country demonstrate the ravages of this pest, it is noticed that the ermine caterpillars begin to feed in the autumn, like the brown tail, then commencing again in the spring, they are of a size to do mischief more rapidly than they can with their English habits. Hawthorn hedges near orchards do sometimes appear to draw away the ermine moths from the fruit trees.

An insect of the same group, but smaller, lives, in some instances, on the buds of the Apple; it is popularly called the "red bud caterpillar" from its deep red hue; the moth is the "black cloak" (*Spilonota cynobattella*), allied to the "brown cloak," unpleasantly abundant as caterpillars upon Roses during some summers. As the eggs are laid singly it is almost impossible to discover them, else there is a long space while life is dormant in them, the caterpillar seldom appearing until the blossoms open, when they are gummed together by the insect, which migrates from flower to flower till full fed, and should supply run short burrows into any immature fruit it finds. This is a species which sometimes gives trouble in houses, where the ermine moth seldom enters.—ENTOMOLOGIST.

## ORCHID NOTES.

ORCHIDS AT WYNCOOTE.—In Mr. C. W. Neumann's garden at Allerton there is a narrow house between the other houses, in fact it connects the two, and has a central path with a narrow stage on each side. This house has been gay with Orchids in bloom. A plant of *Lælia superbiens* was very noticeable. It is a strong grower, and the flower spike was fully 5 feet in length, with fifteen or sixteen large flowers at the end. The individual flowers are 3 or 4 inches in diameter, and of a beautiful deep rose, marked with dark red, the lip being crimson and yellow. *Phalænopsis* were also very fine, especially *P. Schilleriana*, which have been grown in the stove and placed in their present position while in flower. The whole of these are grown on large blocks of wood, with a small portion of sphagnum moss. The blocks are secured in 10-inch pots by means of charcoal, which is covered with moss to retain moisture during the summer. The numerous roots have attached themselves to the wood, and extend in some cases 18 inches below the plant. The healthiest and most robust of these plants is now bearing 120 flowers, and was raised a few years ago from a flower stem. *Dendrobium Ainsworthii*, a good dark variety, was in full beauty, also *D. Wardianum*, *D. Devonianum*, and *D. crassinode*, a fine variety. In another house I noticed some fine plants of these varieties swelling their flower buds, and the old *D. fimbriatum*, which has generally been seen at St. George's Hall in such splendid condition, was showing flowers in abundance as usual. I also observed in a basket a splendid piece of that useful and beautiful *D. Dearei* growing most luxuriantly. Several forms of *C.*

Trianae were in bloom, both light and dark forms, and also D. Percivaliana, Coelogyne cristata, of which Mr. Mease has some splendid plants, and several Odontoglossums were in bloom.

Orchids are not numerous, but there is probably as many Cattleyas and Laelias represented by grand healthy pieces that would fill a large house. The house, in fact, where Mr. Mease has grown such flowering plants as Stephanotis, Clerodendrons, and others, was ready for their reception. The Cattleyas had previously been grown in the Croton house and the general stove, where most of them had to be grown when shade was necessary. The plants that have been subjected to this treatment are all strong and healthy, which affords another proof that Orchids can be successfully grown in mixed collections of plants. They certainly are better by themselves if houses can be provided for them, but where such is not the case cultivators need not be deterred from growing a few with other plants.—W. B.

## THE WEATHER AND VEGETATION.

### ENGLAND AND WALES.

#### BEDFORDSHIRE.

THE early part of January opened fine, but on the 7th the mercury of the thermometer fell to 20°, or 12° of frost. From this date snow and sharp frosts followed, but on the 13th the temperature rose to 39°, but during early morning rain and snow fell, and at 9.30 A.M. a storm of unusual violence, accompanied with rain and hailstones, passed over this neighbourhood from the north-west, doing considerable injury in some parts of the county, uprooting trees and damaging glass structures. From the above date to the 14th February frost and snow followed; the temperature rose to 34° on the 14th, but from this date to the 18th March we had frost for thirty-two consecutive nights—very unusual weather for the month of March; in fact, I cannot remember such a long spell of frost and snow. The sharpest frost of the season occurred on the 7th of March, when the mercury of the thermometer fell to 15°, or 17° of frost. Although we registered frosts on eighteen nights during March, taking the three months of the present year the frost has been more persistent than severe. The day temperature has been unusually low, the thermometer seldom registering more than 42°, or 10° above freezing point, at midday. On March 18th, from 6 A.M. to 12 P.M., the temperature rose from 26°, or 6° of frost, to 48°, or 16° above freezing point, a rise of 22° in six hours.

The drought of the past year and the late severe weather has greatly reduced the garden produce. Never do I remember during my gardening career such a scarcity of common vegetables as at the present time. Kitchen gardens as a rule look like barren wastes, and the outlook for the next two or three months is anything but encouraging. The old stools of Cabbages are all killed, the autumn-planted stock is nearly as bad, Brussels Sprouts are over, and the different Kales are nearly all used; as for Broccoli, I fear many of them will be killed. Turnip tops in previous years have been very valuable, but this season they are very scarce. The same remark applies to Swedes and other root crops. This is owing to the drought of the past year. Parsnips are selling at from £6 to £7 per ton, owing to the long continuance of frost. The market gardeners are very much in arrears with their work; in fact, quite three weeks or a month behind. Several breadths of Onion bulbs for seeds are not yet planted, and very little Onion seed has been sown, which in favourable seasons is usually sown in February. In previous years most of the early Potatoes have been planted by the middle of March, but much ground is unprepared for crops. Great mortality has taken place amongst our feathered songsters; many blackbirds and thrushes have been found dead, and some of the rarer finches, such as the hramble-finch. The house sparrows seem to have held their own, as we know too well, for they have made sad havoc with the buds on Gooseberries, young Cabbage plants, and Spinach. We usually use black cotton strung about the bushes after pruning. This plan has been found sufficient for the sparrows until this season. Bullfinches have been busy amongst the fruit buds, not only Gooseberry buds, but also Apple-bloom buds. We have found it necessary to cover our Gooseberry bushes with nets as well as the cotton plan after pruning. Fruit trees generally seem well set with blossom buds. The Pears, in spite of the long-continued frost, seem to be swelling fast; Peach and Apricot bloom are beginning to show colour.—G. R. ALLIS, *Old Warden Park, Biggleswade.*

#### BERKSHIRE.

It is pleasant to be able to notice that in view of a thorough break-up of the long wintry weather we may now look forward for a favourable fruit season. We are now able to see to what extent plants have suffered from the past severe weather. All vegetables are cut; the recent cold cutting east winds told more upon them than the whole winter, which, no doubt, will have done so, more or less, in different localities, varying with the latitude and elevation in which they are grown, also with the nature of the soil. Broccoli are very much cut, also Lettuce. Some varieties of Strawberries are looking bad just now. Roses, I find, have also suffered; but I am pleased to say our fruit trees are looking well, and since the change both Apricots and Peaches are coming into bloom. Should we have mild nights, with hot sunshine, no doubt they will soon be all out. Our temperature on the 19th ult., at noon, stood at 85° in the sun, with a night temperature on the 20th of 45°.

The winter commenced here on October 12th, 1885, when 6° of frost

were registered, and Scarlet Runners, &c., were cut down. After two or three mornings' frost fine weather followed till October 29th, when 8° of frost were registered, the daily readings varying from 4° to 8° till the night of November 14th, when the thermometer registered 14° of frost, and winter fairly set in, with ice 1½ to 2 inches in thickness, though the frosts at this period were rimy, and heavy fogs prevailed. During November the sun only appeared on eleven days, and then only for a very brief period at noon. December was a brighter month. The sun appeared on seventeen days; keen frosty nights, and E. or N.E. winds: 16°, 12°, 17°, and 17° of frost was registered on the 9th, 10th, 11th, and 12th respectively, also 15° at Christmas. The new year opened with sunless days and foggy nights. On the 6th of January the temperature rose, and snow fell to a uniform depth of 10 inches. On the 7th, 21° of frost was registered, and on the 8th, 28° of frost (being the lowest reading here since December 24th, 1877, when the thermometer fell to zero). On the 11th a thaw set in, snow now fast disappearing, and 1.31 inch of rain fell in twenty-four hours.

The weather during February and beginning of March was more trying. 12°, 16°, and 18° of frost were frequently recorded, with bitter cold east winds: 16° was registered on March 17th, and 5° on the 18th, when a gradual thaw set in, and rain fell. As already stated, the minimum temperature during the night of the 20th inst. being 45°. The air is now soft and spring-like, with westerly breezes; the maximum reading of thermometer in the sun being 81°.—THOMAS JONES, *Royal Gardens, Windsor.*

#### CHESHIRE.

AFTER such a long winter we have been quite busy these last few days, getting Peas and Beans and other vegetables planted into the open ground that were ready started in boxes. I do not observe extraordinary damage to plants and shrubs, and not a Laurel appears to be injured, when they were all cut down in the three successive hard winters that we had nearly ten years ago. I have not kept an exact record of the temperatures, but the most that we had was above 24° of frost, and the greatest depth of snow did not exceed 6 inches here on the level.—R. MACKELLAR, *Abney Hall Gardens, Cheshire.*

#### DURHAM.

THE late severe snowstorms, which have been more or less continuous during the last three months, caused grievous distress, as all outdoor occupation, and especially land labour, was suspended for a considerable time, caused either by snow or frost, though the latter has not been so notably excessive as in the winter of 1880-81, which at the extreme was 8° below zero. The severest nights of this winter were the 18th and 19th January, which registered respectively 22° to 24°. On March 19th we had a decided change for the better, the wind veered from east to west. The effects of the storm have been much felt by vegetables; young Cabbages are flat and black, but most of them are, I think, sound at heart; Early Broccoli, no doubt, has suffered a good deal, but the late varieties, I think, will escape with a good majority, but Globe Artichokes I fear are all dead. Fruit buds of all kinds are remarkably quiet, except Apricots, which are scarce, and require protection.—R. WESTCOTT, *Raby Castle Gardens.*

#### ESSEX.

THIS has been a long and trying winter. The frosts have not been so intense as in some winters, but they have been more continuous. The lowest registered was 21° of frost on the 8th January, and 19° on 7th March. All green vegetables are much injured, many of the Broccoli are killed, Brussels Sprouts, Cabbage plants, Spinach, and Parsley present a scorched and withered appearance; even Leeks are injured. Wall-flowers, Stocks, and Pentstemons are nearly all killed. Shrubs appear to have escaped.—H. LISTER, *Easton Lodge Gardens, Dunmow.*

#### GLAMORGANSHIRE.

THE winter hereabouts is regarded as the most severe in memory. Some very severe weather was experienced in November and December but it was worse in February and March than previously. On several nights in the first week in February we registered from 10° to 16° of frost, then it became very mild and fine, but on March 1st snow fell to the depth of 6 inches; 17° of frost was experienced during the following night, and from then until March 18th we had from 8° to 14° nightly. On parts exposed to the sun the snow gradually disappeared, but in the shade it was not reduced until we had a thunderstorm on the night of March 18th, followed by rain for two days, when a complete thaw was the result. Trees and shrubs do not appear to have suffered very much, but they are unusually late. Vegetables have suffered severely; spring flowers have had a hard time; fruit trees, especially those on the walls, are later in blooming than I ever remember them, as we have often had the Apricots in blossom in February and the Peaches almost full out by the middle of March. The fields are as bare now as at midwinter, and the farmers are feeling severely the want of herbage for their sheep, lambs, and general stock.—J. MUIR, *Margam Park, Port Talbot, S. Wales.*

#### NORFOLK.

A LONG trying winter, which will be memorable here for its persistency more than for its severity, finally broke up on March the 19th, having begun about December 9th with a fall of snow. The snowstorms in Norfolk have not been so heavy as in other parts of the country. The

heaviest experienced here was January 7th, which laid about in drifts until the change of weather set in. The ground has been tolerably clear of snow throughout the winter, giving farmers and gardeners a chance to proceed with manuring. Garden crops, through the absence of snow, being so much exposed to the severity of the weather, had a scorched appearance, but have suffered but little. All fruit trees are well set with fruit buds and promise well for the coming season. The mild weather has worked a marvellous change. Grass and crops are everywhere green. The spring flowers have come with a rush, and are already plentiful. Iris reticulata, in flower last year with me on February 10th, did not open a bloom in the open border until March 22nd, and is now a mass of bloom, and the most striking object in the garden at the present time.—W.M. ALLAN, *Gunton Park Gardens*.

## NOTTINGHAMSHIRE.

THE winter in this district has been a long and trying one for all kinds of vegetation. Commencing early in November, we had frost and snow until December 14th. From that time up to January 3rd it was comparatively mild; a period of frost and snow then set in without intermission up to March 19th, from which up to March 27th the weather was remarkably mild, and the effect on early spring flowers is magical. Snowdrops, Crocuses, Hepaticas, Scillas, Daphnes, Daffodils, Primroses, and Violets are all in flower together. The most severe frost we had here was on the 7th of March, when we had 25° of frost. Brussels Sprouts, Broccoli, Lettuce, Celery, and Cabbage suffered severely. Veitch's Model Broccoli, Asparagus Kale, and Sprouting Broccoli have stood well. Portugal Laurels have suffered the worst amongst shrubs, a few of them are killed in places exposed to the east wind. Roses are safe, no doubt the snow saved them; all fruit trees are now swelling their buds, and are promising well for a good crop. Taken altogether, the past winter will be long remembered for its unusual length and sunless days.—J. EDMONDS, *Bestwood Lodge Gardens*.

## RUTLANDSHIRE.

JUDGING from the reports published we have been more fortunate in the midland district this season than our neighbours either north or south. We have had a long winter and much frost, but at no time very severe, the most we have had being 15° on December 11th, and also on March 7th, as registered by a thermometer certified at Kew, and which hangs in a Stevenson screen. We generally get 4° or 5° more than our immediate neighbours, as this place is situated at the bottom of a valley with a stream of water running through it. The only plants generally considered hardy here that have suffered from the frost, &c., are Wallflowers, Brompton Stocks, Spinach, Myosotis disitiflora, and Victoria Regina Violets. The last three are severely affected. The common Laurels are very slightly browned.

The average maximum temperature here for the seventy-seven days, ending March 18th, is 38.89°. Average minimum in the screen for the seventy-seven days, ending March 18th, is 28.63°. Average minimum on the grass for the seventy-seven days, ending March 18th, is 28.02°. Total rainfall for the same period, January 1st to March 18th inclusive, 4.40 inches. Frost this season commenced suddenly on September 26th, and Heliotropes, Dahlias, Pelargoniums, &c., were cut very much. Highest shade temperature in September was 75° on 15th; total rainfall for the month 3.01 inches. October was very changeable, with several slight frosts and much rainy weather. Highest shade temperature was 63° on 16th; lowest in screen, 29°, on the 30th; lowest on grass, 30° on 25th and 30th; total rainfall for the month, 5.42 inches. November was another rainy month; the total rainfall was 3.11 inches, which fell on twenty-three days. On the 27th we had a very heavy hailstorm with thunder. The highest shade temperature was 57° on 28th; lowest in stand 21° on 16th, and 22° on 19th; lowest on grass, 24° on 16th and 19th. December was very changeable, but principally dull damp weather. The first snow of the season, only a few flakes, fell on the 4th. Lowest temperature in stand, 17° on 11th; lowest on grass, 20° on 11th; highest shade temperature, 53° on 17th; total rainfall, 0.92 inch, which fell on seventeen days. January was a very wintery month, much snow fell, which, as a rule, soon melted, but on the morning of the 25th it was 6 inches deep. The ground was covered with snow from 20th to 31st. Highest shade temperature, 52° on 3rd; lowest in screen, 21° on 19th; lowest on grass, 22° on 10th and 19th; total rainfall, 3.07 inches. February was remarkable for a low temperature and absence of either rain or snow, only 0.30 inch falling during the month, and this fell during thirteen days. Highest shade temperature, 51° on 14th; all other days the maximum was below 46°, and on seventeen of them it was below 40°; lowest temperature in screen was 19° on 15th and 20th; lowest on grass, 23° on 7th, 15th, and 27th. The wind was in a northerly direction nineteen days, and eastward thirteen days during the month. March began very wintery, snow falling all day on the 1st, and was 4 inches deep at 6 P.M., and this had not all melted on 16th, when we had another snowy day, the fall being equal to 0.21 inches of rain, but fortunately a change to milder weather set in on the 18th, which it is hoped may now continue.—W. H. DIVERS, *Ketton Hall, Stamford*.

## SOMERSETSHIRE.

THE winter of 1885-6 has been the most protracted and trying that has occurred within memory. The frosty and easterly winds were the worst, especially during the early part of March. We had severe frosts early in December and again early in January. On the night of January 7th the thermometer fell to 11°, or 21° below freezing point. During the

early part of March we had sharp frosts every night, ranging from 6° to 18°, and on March 7th we experienced 22°. On March 18th we had a sudden change, and, on the whole, so little harm has apparently been done that we have ceased to grumble about the weather. We had but little snow, the most being on March 5th, or about 3 inches, and the bulk of this soon disappeared. Conifers and other trees are uninjured. All the winter vegetables have a scorched appearance, but none is killed, neither have we failed to maintain a fairly good supply of Brussels Sprouts and Kales, owing to the firm growth, consequent upon planting on firm ground. The Green Curled Borecole has been especially serviceable, while the Asparagus Kale will shortly yield numerous gatherings. Tripoli Onions, Parsley, and Cabbage plants are very scarce. A great number of birds died from starvation, but I find there are plenty left, more blackbirds than are wanted in fact, and, strange to say, a considerable number of slugs were to be seen directly the change came. Our clayey soil now works well, and as we shall have abundance of bloom on all fruit trees I am looking forward to a prosperous year.—W. IGGULDEN, *Marston Gardens, Frome*.

## STAFFORDSHIRE.

MY own experience is that the winter has been most disastrous to all green vegetables; Borecole stood fairly well; Broccoli was nearly all killed; autumn-planted Cabbage very much cut; Veitch's Matchless and Ellam's Dwarf has stood the best; Early Heartwell is nearly all gone; Brussels Sprouts are much injured; the Aighurth has escaped the best, and is invaluable at the present time; winter Spinach where fully exposed suffered very much, but where sheltered by a range of houses is fairly good and will be very useful as a green spring vegetable. Where houses and pits can be spared it will be a good plan to grow a supply of French Beans to meet the difficulty as far as possible, also hasten the growth of autumn-sown Cauliflowers by planting them in frames with a gentle bottom heat. As far as I can see at present Roses are not much hurt; shrubs generally I do not think are injured to any great extent. The lowest temperature registered here was on the 6th of March, when we had 20° of frost.—G. H. GREEN, *Enville Hall Gardens, Stourbridge*.

## SUSSEX.

BRAMBLETYPE stands on a high exposed situation 400 feet above the sea level, but we did not get the frost so severe—from 11° to 18° this winter—as our friends in the valley, but we are exposed to the east wind, which affects tender shrubs and plants seriously. The Brassicas, both young and old, have suffered greatly; from a bed of 400 Cabbages planted in October not one plant remains, and all the old stems are killed. Brussels Sprouts and Borecole are nearly as bad; Savoys and Celery (Grove's Red) have stood well; Spinach, Lettuce, and Turnips are complete failures, being destroyed by wind and frost. Fortunately, with the help of some dozen spare lights, I made a reserve in January of Cabbages, Cauliflowers, Lettuces, Carrots, Radishes, &c., which will prove useful this year, and I have looked carefully over my Broccoli and am glad to find my old favourite, Knight's Protecting, the best; the others are Miller's Dwarf, Cattell's Eclipse, and Wilcove. We have 95 per cent. of the first, and about 40 per cent. of the three others.

Wallflowers are much injured, and it is doubtful if they will break again. Violets on north, east, and west borders are as bad as if they had been salted. Forget-me-nots, Aubrietia, and Pansies, are destroyed by hundreds. Shrubs have not suffered much with us, common Laurels are the worst; Roses very doubtful. Fruit trees are safe except Peaches, and some of the immatured wood must be cut back hard, but we need not fear for a crop. In the year 1880 I cut back closely, and had a good crop of fruit and well-furnished trees. I have tried it both inside and out, and have never failed with a crop.—SAMUEL JENKS, *Brambletype Gardens*.

## WARWICKSHIRE.

THE frosts and snows have not been so severe with us as in some parts of the county, still the winter has been long and cold. For over four months we have had little sunshine, the wind north, north-east, with occasional snowstorms and frost nearly every night. The heaviest fall of snow was on 1st March, when 9 to 12 inches fell during the twenty-four hours it lasted. On 7th January and 7th March we registered 18° of frost, the most this winter. The effects on vegetation will not be known for some time. That vegetable crops have suffered very much, and spring hedding have all perished. Eucalyptus globulus that have stood the previous winters, and attained the height of 15 feet, I fear are killed. Since the 19th we have had a marvellous change, can almost see the buds and flowers expanding. First Apricot blossoms opened on the 25th, over a fortnight later than usual.—A. D. CHRISTIE, *Castle Gardens, Warwick*.

## WILTSHIRE.

THE long-looked-for change in the weather took place here on the 18th inst. In glancing at the green crops in the kitchen garden conclusive evidence is there afforded of the weather which we have experienced. A reserve stock of autumn-raised Cabbage plants has suffered severely owing to their stems being exposed to the frost, though, fortunately, those which had been planted from the same sowing in drills 2 feet apart in September last, and which were landed up in due time, have suffered comparatively little injury. But in view of the break which the loss of the reserve plants would otherwise make in the supply of young Cabbages, which will be fully six or eight weeks late this season, we are pushing on the plants raised in heat in January last, some of the plants being pricked out in flower boxes and placed near the glass

between the rows of Potatoes just appearing above ground, and others in improvised frames on warm borders. Consequent upon the favourable change in the weather good plantings and sowings of Potatoes, Cauliflowers, Lettuces, Peas, and Broad Beans and Spinach were made forthwith, also of Cabbage, Cauliflower, Brussels Sprouts, Savoy, Carrots, Parsnips, Lettuce, and Leek seed. Several dozen ranks of Peas and Broad Beans were transplanted from pots and boxes early in February, and by way of showing that the plants after being raised in forcing houses had been properly hardened, it may be interesting to state that notwithstanding the severe frosts and easterly winds which these Peas and Beans experienced during the interval, not a single plant of either has been killed. On the contrary, the plants, though very little advanced in growth since they were turned out of the pots and boxes, are in capital condition. The varieties referred to are Sutton's Ringleader and William I. on warm borders, Carter's Telephone, Carter's Pride of the Market, Carter's Stratagem, and Culverwell's Telegraph in open plots of ground, and in the same situation are ranks of Carter's Leviathan Broad Beans, the individual plants being supported by a stick. Seeds of Webb's Wordsley Wonder and Chancellor Peas, which were sown on the 1st of February, I find, by examining the soil, are just pushing into growth. I sowed my Onions on the 20th of February, when I also made a sowing of Turnips. From the 15th of February to the 18th inst. there have been from 2° to 18° of frost every night, that of the 7th being the most severe.—H. W. WARD, Longford Castle.

#### HARDY FRUIT GARDEN.

SWELLING huds remind us that fruit blossom will soon be open, and no time must be lost in providing all available means of shelter to afford protection against cold winds and late frost. Wall copings of glass or wood should now be in position, and if we are so fortunate as to have plenty of hexagon netting, a double covering of it stretched tightly over poles driven into the ground, and fastened to the coping so that the netting is about 2 feet from the trees, answers admirably to protect blossom and foliage. Do not forget that a little extra care now may save the fruit crop; without it the crop may be lost. Hurdles thatched with straw, garden mats, branches of Fir and Yew, dried bracken, are all useful for various purposes of shelter, and all should be turned to account. Whatever is used see that there is no risk of its being loosened by high wind, or the blossom which it is intended to protect may be battered to pieces by it. Bracken may be shaken lightly upon the tops of Gooseberry bushes as a means of protection from late frost, which not unfrequently destroys the crop.

New Strawberry beds may now be made if a due provision of plants was made last autumn by planting rooted runners thickly in nursery beds of 6 or 8 inches of rough leaf mould. Once established in such material the plants are lifted with a large ball of roots and soil, they are soon growing freely in the fruiting bed, they will afford a few fine fruits this year and a full crop next year. This method of making new Strawberry beds is especially recommended for small gardens where space cannot be spared in July or August. Plant in well-drained, highly manured soil, in rows 2 feet apart, and with the plants a foot apart in the rows. Do not forget that now and onwards through the season of growth Strawberry plants are much better for a liberal supply of liquid manure, and this may easily be had for every garden in the convenient guise of house sewage. It is withheld as the fruit approaches ripeness, but it is again given after the fruit is all gathered to promote the development of strong plump crowns, from which spring the fruit crop of the following season.

As the catkins of Filbert and Nut trees become fully developed and shed pollen freely upon the pink female blossoms, the pruning may be done, care being taken to keep open the middle of each tree so as to give free admission of light and air to every part of it. In the extensive Filbert plantations of Kent the form of a shallow basin is imparted to the trees by careful training and pruning, that form being the best for the production of full crops of nuts.

#### FRUIT FORCING.

PINES.—Utilise solar heat as much as possible, employing no more fire heat than is absolutely necessary. Attend to watering regularly at least once a week, each plant being examined before water is given, and when needed supply sufficient to moisten the soil down to the drainage. Syringing may now be more freely practised at the time of closing the house for the day. Disturb fermenting beds but little, or the heat may be increased to an extent that will be injurious to the roots. Plants placed near large squares of glass will be much benefited by slight shade during the hottest part of sunny days, until the tissues of the leaves have become more hardened. Examine fruiting plants occasionally, and remove all suckers not wanted for stock, stake the fruit to keep it in an erect position. The temperature in fruiting houses should range from 70° to 75° at night, and 80° to 95° by day, successional plants 65° to 70° by

night, and 80° to 90° in the day, the younger stock of plants not taking any harm at 60° at night, and a proportionate rise in the daytime according to the weather.

FIGS.—*Early-forced Trees in Pots.*—When the fruit show signs of ripening the ventilation may be increased, and the flavour will be much improved by full exposure to the sun. Many of the fruits on large pot trees cannot have this, but judicious stopping, thinning, and tying will help them, as Figs ripened in a close moist house are insipid. Figs under glass have two enemies—viz., red spider and brown scale. Red spider does not make much progress under good syringing, but when atmospheric moisture is reduced it increases rapidly, and on this account no effort should be spared to keep the foliage quite clean up to the ripening time. Brown scale also spreads rapidly over the young shoots, and extends to the leaves and fruit. Spare no pains to prevent this by the timely use of an insecticide, carefully using it with a brush or sponge upon the first appearance of the pest. Supplies of water at the roots are needed through all stages, and favourable opportunities for washing the trees may often be found through the ripening season by gathering all the ripe fruit at one time. For private use Figs should be ripe when taken from the trees, but for market purposes they must be gathered before they are fully ripe. The temperature should be 60° to 65° at night, with a little air, and 80° to 85° by day. Top ventilation must be given at 70°, and increased at 80°, with plenty of moisture rising from water applied to the mulching.

*Succession Houses.*—Permanently planted trees in borders inside will now need large quantities of water through the mulching. Syringe twice a day. Let the night temperature range from 55° to 60°, 70° to 75° by day, with gleams of sun, and 80° from sun heat, ventilating from 70°, and fully at 75°, but with an advancing temperature to 80° or 85°, closing at 80°, and sufficiently early to cause the temperature to rise 5°.

*Late Houses.*—Trees in these and wall cases must now be tied in and syringed on fine days, but sufficiently early to allow the trees becoming dry before night. In low cold localities unfavourable to the culture of Figs on walls, excellent crops may be grown under glass, but cold houses are not the best to insure annual success, there should be some provision for keeping out frost in the spring and ripening the wood in the autumn. Fires are unnecessary through the winter, and possibly injurious, as the trees may be unfasted in the autumn, tied in bundles, and protected with dry straw or bracken, and with dryness at the roots they will have a safe and complete season of rest.

PEACHES AND NECTARINES.—*Earliest House.*—The stoning process with Alexander and Waterloo (the two best very early Peaches) will soon be completed, and may be given a temperature of 70° to 75° by artificial means, but as this attenuates the wood if continued through the night, the temperature should be allowed to fall 5° through the night, and the temperature from sun heat may be kept through the day at 80° to 85°, ventilating by the top at 75°, and opening the front at 80°, so as to insure a circulation. Admit a little air constantly. Close the house at 80°, and sufficiently early to allow of an advance to 85° or 90°, the trees being well syringed and a good atmospheric moisture secured, which will insure the fruit swelling to a large size, but the foliage and fruit must become fairly dry before night, and clear rain water must be used, as spring water is liable to leave a stain upon the fruit. Remove the leaves over or in front of the fruit, and turn it up to the light by thin laths placed across the trellis, as it adds greatly to the appearance of the fruit when it is well and evenly coloured from the apex, besides making all the difference between high and poor flavoured fruit. Syringing should cease when the fruit commences ripening, but a genial condition of the atmosphere must be maintained for the benefit of the foliage by damping available surfaces twice a day and keeping the mulching thoroughly moist. Grow the very early varieties in a house by themselves, as they precede Hales' Early and A Bec by nearly a month, and Royal George by six weeks. If they are grown with the last-named, then the night temperature must not be more than 60° to 65°, and 70° to 75° by day with gleams of sun, and 5° to 10° advance on bright days until the stoning is completed, in another fortnight or three weeks, if the trees were started in December to ripen Hales' Early by the end of May. The prolonged cold weather has retarded forcing considerably, and when the stoning is completed they will bear a considerable advance in temperature with safety. Pay particular attention to syringing the trees, using clear soft water twice a day, and see that every part of the foliage and old wood is thoroughly washed. Keep the roots well mulched and supplied with weak tepid liquid manure. Regulate the flow of the sap by stopping all gross shoots before they have time to draw the supplies from the weakest parts of the trees. Allow leading shoots, particularly of young trees, to extend over uncovered parts of the trellis, and pinch out the points when the fruit begins to take the last swelling, at the same time turning aside any leaves that are likely to shade or otherwise interfere with the colouring or ripening.

*Second House.*—The trees in the house started early in January will have the fruit in a forward state, the disbudding completed, and the shoots that are to succeed those now fruiting have been heeled in. Allow plenty of room in the ties, and do not keep them very closely tied down for some time longer. Allow no more growths to remain than are necessary for next year's fruiting or for the extension of the trees. Stop gross growths or remove them, as it is highly important the sap be equally distributed, and an equality of vigour maintained through the branches of each tree. Pinch laterals at the first joint, and shoots retained to attract the sap to the fruit should only be allowed moderate extension, stopping them in the first instance at three or four joints of growth. Endeavour to provide an equal distribution of foliage that will

shade and protect the strong wood from the direct rays of the sun as the season advances. Avoid overcrowding, not allowing more shoots than can have full exposure to light and air. Ventilate freely but carefully, so as to avoid cold currents of air and sudden depressions of temperature. As the fruits will be swelling fast thin it if too thick, as with the trees in good health the fruit is more likely to stone well than when they are overburdened, besides taking from the size of those that remain for the crop at the final thinning after stoning. Water the inside border copiously, and keep them well mulched with short well-worked horse dung.

*Third House.*—Trees started early in February should be examined frequently for disbudding, and as this is best done gradually the strongest parts of the trees should be first commenced with, being careful to preserve a shoot at the base of the current year's bearing shoots, and to leave no more on the extensions than will be required for furnishing the trees with bearing wood at 15 to 18 inches apart, and all the others on these may be pinched in closely to form spurs. A shoot on a level with or above the fruit must be retained on each bearing shoot and be pinched at the third joint. As the fruit is swelling freely remove those worst placed, and leave only a few more than will be required for the crop, one fruit to every square foot of trellis covered by the trees being ample. Syringe early on fine mornings, give a little air shortly afterwards, gradually increase it, and close with a rise from sun heat about 3 P.M.

*Fourth House.*—Trees started early in March will be out of bloom, and should be fumigated if there is any trace of aphides on two or three consecutive evenings. Syringe morning and early afternoon, and see that the inside borders do not lack moisture. Proceed with disbudding gradually, and rub off all small and badly placed fruit as soon as the most prominent show signs of taking the lead. Ventilate freely on all favourable occasions, and close early with a view to husbanding the sun heat.

*Late Houses.*—The trees in these are unusually backward, but this is none the worse, as the blossoms are usually stronger and set quicker than when brought forward by mild weather in the early part of the year. Ventilate freely until the blossoms begin expanding, but keep them safe from frost. When the anthers show turn on the heat in the morning so as to raise the temperature to 50°, and keep it at that with a gentle circulation of air, turning off the heat early in the afternoon so as to allow of the pipes cooling before night, and the temperature falling to its night minimum of 40° to 45°, which is quite safe, and ought to be secured after the blossoms expand, with a little air to prevent the deposition of moisture through the night on the flowers. Artificial impregnation should be resorted to either by shaking the trees, or by dusting the flowers with Pampas plume, or camel's-hair brush, but the best aids to a good set are proper borders full of active roots, kept so by constant attention to lifting, root-pruning, and the addition of fresh calcareous food with rich surface dressings.

#### PLANT HOUSES.

*Azaleas.*—As these plants cease flowering they should be pushed into growth at once by placing them in a temperature of 55° to 60° by night, with rise of about 10° from sun heat by day. Directly the roots are active pot the plants if they need more root room. Those that do not need repotting may have during the season two or three applications of artificial manure applied to the surface with advantage. Shade must be provided for a few hours during the hottest part of the day, and the atmosphere must be kept moderately moist. All plants required for late flowering should be in some structure with a northern aspect, and must be kept as cool as possible. They come forward rapidly at this season of the year in the houses exposed to the sun. In such houses ventilation must be provided day and night, whenever the weather is favourable, and heavy shade, applied during the day.

*Epaerises.*—Except the latest these will have flowered, and should be cut back without delay and introduced into a temperature of about 50° to 55°. If kept moderately close and syringed twice daily they will soon break again in growth. The earliest flowering plants will have made 2 inches of growth, and will be ready for repotting if they require more root room. In potting the roots should not be disturbed further than the removal of the drainage from the base. The soil used should be pressed firmly into the pots and the plants watered afterwards with great care. If they are kept close, slightly shaded from the sun in a moderately moist atmosphere, they will be rooting in the new soil in about a fortnight. When they reach this stage they should be gradually hardened to cool treatment or their shoots will draw up weakly. Care must be taken that the plants are not checked.

*Camellias.*—As these cease flowering start them into growth by keeping them in a close moist atmosphere where the temperature at night can be maintained at about 55°. The house at which they are grown should be lightly shaded for a few hours daily during bright sunshine. Syringe the plants liberally, and throw plenty of water about the paths and stages of the house. As soon as growth is visible repotting may be done. Camellias do well in a mixture of fibry loam, one-seventh of decayed manure and a liberal dash of coarse sand, or they may be successfully grown in equal proportions of loam and peat. Provide liberal drainage, for these plants when in active growth require abundance of water, in fact they must never suffer by an insufficient supply in any stage of growth. Carefully remove the old drainage and any loose soil into which the roots have not entered. Pot firmly, but do not bury the collar of the plant below the surface of the soil. Plants in tubs or large pots, that it is not necessary to repot, may have the surface soil removed and then top-dressed with fibry loam and one-third of manure. A little artificial manure applied to the surface of the soil about once every three weeks will prove advantageous to these plants, or they may be given weak

liquid manure every time they need water. If the plants are infested with scale syringe them before the growth is advanced with petroleum and water, one ounce of the former to one gallon of the latter. This is an operation for two persons, the one to syringe into the pail, while the other distributes it upon the plants. Shade the plants from the sun for a few days afterwards.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

*Shrubberies.*—A busy time has arrived, much work in all directions now requiring to be done before it is too late. Hollies, Conifers generally, Box, Phillyreas, Aucubas, and various other evergreens may yet be safely transplanted, care being taken in every instance to preserve as much soil about the roots as can be retained without unduly increasing the weight. Unless the soil is very loose no great difficulty need be experienced in securing a good ball of earth about the roots if sufficient time is allowed to do the work properly. The start should be made at a good distance from the stem of the tree, the trench being cut slightly deeper than the principal roots. This renders the gradual undermining, as well as the preservation of many of the roots, a comparatively easy matter, the tree being eventually well balanced on a short stout plant barrow, or a legless hand barrow, and on this transferred to its new site. No attempt should be made to drag out a tree or shrub, neither should they be cramped in small holes with nothing but poor soil to root in. The new sites should be of good width and depth, and a liberal addition of leaf soil or other good light compost be well mixed with the ordinary soil. Either common peat or leaf soil must be freely added to the ordinary soil where Rhododendrons and Belgian Azaleas are to be planted, or in most cases failure is certain. Cutting evergreen hedges and banks of Laurels should now be completed, and this is also a good time to cut down tall and unsightly Laurels, Laurustinuses, Yews, Tree Box, Hollies, Portugal Laurels, Lilacs, Rhododendrons, and other trees and shrubs, most of which will soon break afresh from the old stems, and in time grow into handsome trees. Use the saw for all stout wood, the edges of the cuts being neatly rounded with a knife. Jagged wounds do not heal so surely, especially if they hold water.

*Climbers.*—Ivies are improved by being shorn closely to the wall, as they soon form fresh bright green leaves, and are much less liable to become detached from the walls. Where it has reached the water-shoots or eaves of the roof, unless it receives rather severe trimming it may soon become a nuisance. In such cases cut it clean away from the wall for at least a yard from the top. Evergreen Magnolias require little or no pruning, but unless the principal branches are secured to the walls, and the smaller branches tied to these, they are liable to be much damaged by winds. Virginian Creepers, notably Ampelopsis Veitchii, require but little assistance, but it is advisable to cut away all loose growths, unless these are leading shoots, in which case they should be fastened to the wall or woodwork. All loose growth on Passion-flowers may be cut back to the principal branches, the flowers being produced on the young growths resulting. Wistarias also must be spurred back, only a few thinly disposed main branches being kept properly fastened to the walls, and plenty of bloom should thus be secured. Cut back Jasminum nudiflorum and Forsythia viridissima rather closely after they cease flowering, while the common white Jessamine ought to be spurred in closely now. Pyracanthas require little pruning, but neither these nor Pyrus japonica should be allowed to extend far from the wall. Cut back flowering Loniceras freely, and the golden-leaved Lonicera should also be prevented from becoming bushy and unsightly, a free use of the knife or shears greatly improving its appearance later on. Clematis and Roses were alluded to on page 240.

*Lawns.*—Since the introduction of mowing machines there has been less need for the use of the roller, but the late frosts will have loosened the soil rather more than usual, and a good rolling will serve to fix the roots of some of the best grasses. If there are many wormcasts or moss abounds a bush harrow should first be freely used, or on small lawns a sharp-toothed iron rake may be substituted. Where it is considered desirable to improve the quality of the sward a thin top-dressing of good compost, consisting, say, of good sifted loamy soil, to every twenty bushels of which has been added one bushel each of lime, wood ashes, and soot. This if well raked or harrowed into the surface will soon become incorporated with the old soil, and will quickly effect a change for the better. Where the grass is very thin it is advisable to prick up the surface with garden forks, next giving a good top-dressing of the compost mentioned prior to sowing a suitable mixture of lawn grass seeds. These should be lightly raked in, and if the soil does not pick up badly a good rolling should follow. Levelling and turf-laying may still be proceeded with, and it is not yet too late to drain lawns or tennis grounds when these are too damp and mossy. April is also a good month for sowing grass seeds to form a new lawn, as during showery weather the seeds germinate in a few days, and consequently are not so long exposed to the attacks of small birds. In all cases the ground should be prepared as much as possible during rather dry weather, this admitting of the work being done well. The ground must be made firm, or inequalities will soon become apparent. The greater the depth of soil the more need for extra heavy ramming. The principal seedsmen supply mixtures of seeds to suit all soils and positions, and if birds are troublesome the seed may be sown thinly in drills 2 inches apart and well covered. The turf soon meets.

*Herbaceous Plants.*—Now that the bulbous-rooted plants are showing above the surface the herbaceous borders may safely be overhauled. Such strong growers as Phloxes, Asters, Pyrethrums, Potentillas, Japanese Anemones, Irises, Delphiniums, Spiræas, Hemerocallis, Geums, Tritomas, Hellebores, and Aquilegias are frequently much improved by being lifted, freely divided with plunging forks, and replanted in fresh well-enriched

soil. Unless this is done many of them soon throw up too many growths, and the bloom is much inferior accordingly. Besides, they are great exhausters of the ground, and during hot dry weather especially, present an unhealthy appearance if at all neglected. Early-flowering *Chrysanthemums* are becoming very popular, and they may be largely planted in the herbaceous border. Slugs are rather too fond of the young shoots, but where strong old plants have escaped, these may be freely divided and replanted. We are obliged to winter a few stock plants in frames, and from these we obtain abundance of cuttings, which are struck in boxes in a close frame, stopped once, and planted out early in April where they are to bloom. Some of the best are Mrs. Cullingford, *Précocité*, *La Petite Marie*, *Lyon*, *St. Mary*, *Frederick Marronet*, *Madame Piccol*, *Little Bob*, *Virginia*, *Fiberta*, *Scarlet Gem*, *Madame Desgrange*, and *Mons. E. Pynaert Van Geert*.

## THE BEE-KEEPER.

### INITIATORY INSTRUCTIONS.—No. 2.

WHEN a Stewarton hive is at first stocked with bees, and intended for profit, the swarm should be of sufficient strength to be able to fill two body boxes in about eight days if the weather is favourable. If the bees have swarmed six weeks before the expected honey glut, although the swarm is small, will by that time have made considerable progress if it has been fed a little immediately after being hived. Whenever the two body boxes are filled a super may be placed on; but at this time first swarms are liable to start royal cells and prepare for swarming. To prevent this a third box should be put beneath for a day or two, or until the bees begin to make comb in it, known by looking in at one or both of the windows provided in these hives. When this is seen to be the case the box should be removed and a super put on, unless the one employed beneath was a super, then simply take it out from beneath and place it above. Such a super is a capital inducement for the bees to continue work. If it has been a body box, then lay it aside where it will be safe and ready to do service for some other hive, or it may be the one it has been underneath already.

I used to make my supers with doorways, so that they might be interchangeable. When the supers have no doorway it will be necessary to raise it with fillets of wood, forming a doorway when one piece is kept out. When supers are so used care must be taken not to let them remain too long, else the combs would be discoloured. Of old ekes or "raises" varying from 2 to 3 inches were used for this purpose, as well as for putting underneath the hive during winter to encourage a circulation of air and insure dryness. The ventilating floors obviate these, and are a great improvement. Some of these ekes were used with bars and some without. The objection to the latter was the bees built right down their combs, and when they required removing the combs had to be cut—a rather disagreeable duty to perform, and annoyance to the bees when they were allowed to remain flush with edge of hive. Bees always leave a half-inch space or more between the bottom of their combs and floorboard, and their desire to do this should not be frustrated. The hive that would yield the greatest amount of honey with the least amount of toil for the bees, and the one best adapted to their nature, and by far the best for wintering, would be the hive made of ekes or raises without bars, and the same dimensions as Stewarton. Such a hive, however, would not do for carrying or moving about, and would be very impracticable when depriving the bees of surplus honey.

The best time for adding a second swarm of bees to a Stewarton hive is immediately before the honey glut, and if possible at the time described above for putting on the first super. There are various ways of joining swarms. Success depends entirely on having both lots of bees fully gorged with honey, and when in this state the quicker it is done the better. The way I generally perform the operation is, when I have the swarm secured it is placed near the one it has to be joined to whenever all the bees are settled and come to it. I either get assistance from someone to hold up the first swarm for me, or I place it on a tressle or bottomless stool of a good height; then having some very thin honey and water in readiness (sugar is apt to clog the bees), I take a syringe with a fine rose and spray the bees as well as I possibly can in that position, because to invert a hive with newly made combs would simply be courting destruction. After that one has been operated on I carefully invert the other with bees only and spray them well with the sweetened water; then, quick as possible, with a sudden bump knock all the bees on to the floorboard of the other, on which a few pieces of wood have been laid to prevent crushing the bees when the other has been placed over them, which should be done instantly, and better if the operation has been performed on the ground in front of its permanent stand, so that the bees now heavy will be able to creep into the hive. Many of the bees of the first swarm will have been abroad when operations

were commenced, will now be flying about in a distracted state, but they will be readily subdued and in a fit state for joining peaceably. As a rule when bees are swarming they are filled with honey, and so will all others be that are working in other hives, and might be joined in perfect safety, but this is not always the case, so it is better to use the precautions of spraying with diluted honey. Time means honey with bees, as it means money with man, so if bees can be joined when newly swarmed instead of waiting till night more honey will be gathered; therefore, I advise immediate joining. When bees are left to join themselves by having one lot placed over the other time is lost, and if the upper portion has combs there is a danger of their repelling those below.

When a second good lot of bees has been successfully joined to another good one place two supers on at once, and in a day or two the third body box should be added, and if one can be had full of comb all the better, if not fill with comb foundation. This third box has the effect of encouraging breeding, keeping the queen from the supers, and where the queen is young from swarming, as well as having plenty of empty cells to allow the bees to store as much as possible when the glut is at its height, which seldom lasts long. We may well judge what the future weather will be from that in past years. Dry weather often sets in after a long continuance of wet, when the thermometer registers 32° or a little more, or even less. On the same day after it may rise to 70°, and the bees will appear as if they were seized with madness from their alacrity and helter-skelter out and in the hive. People will begin to ask how long this fine weather will last. Bee-keepers will be very anxious it should do so until the full harvest is reaped, and prophets will fix it at so many days or weeks. Do not mind what any of them say, but watch and weigh your hives, and you will find the income decrease at the end of the third day, and should it continue dry the change will recur every third day until again white clouds skim the horizon, or it may be a small one obscuring the sun when he sinks. The next day the sky may be overcast and the air oppressive, honey plentiful, bees so loaded that they fall short of the hive with a sort of a drowsy and monotonous hum, and at intervals they return in crowds to their hives. When these signs are seen be sure the end of the honey glut is near. I have mentioned these things so as to impress the bee-keeper with the necessity of studying the weather in conjunction with bee-keeping and its study. Bees are capital barometers, and where a journal of the doings of the bees and the weather is kept it materially assists the bee-keeper as well as the farmer as to what work should be performed.

The foregoing is what may be considered the most likely work to be performed, but circumstances may alter the whole proceedings, and after all the young bee-keeper may be unable to carry out the work as advised. Using his own judgment with the advice given may enable him to overcome difficulties. The weather is the main factor. Without favourable weather bees will not thrive. Under these circumstances feed until the weather changes, but never count on more than a week at a time, nor on more than three weeks during the season; and if at any time the three-weeks fine weather continues at a spell be thankful, but always have your hives in good order and things in readiness for fine weather come when it may. Believe that the bees have resources that man has not, and that if they have only room given in time they will collect and store more honey in a perfect state when let alone than when annoyed by man and his devices, which are often of a kind to thwart Nature. Learn to judge for yourselves; always buy the best article, and if ever it comes to be sold it will realise its full value, which an inferior one will not do. Use the microscope for amusement and study. When you have a feeder of the right sort and properly made a lens placed on the top of the glass will show to great advantage the parts of the living bee, and if of the yellow sort a glimpse of their internal parts may be had. A drop of condensed water from their perspiration is a good microscope when viewing the bees through the glass it is suspended on. Turn to the supers, view the bees through the window, and you will see them storing the honey direct from the fields, proving the fallacy of those who say it is first stored underneath and again methodically carried aloft. If you have been attentive readers of modern bee literature think how absurd are some people's teachings when they say the honey must first be stored underneath to be carried aloft during the night. Yet they recommend oblong hives, which precludes its possibility owing to the few frames they employ. They disparage the use of the Stewarton hive which is so well adapted for performing the work according to their own views. Another thing greatly recommended by some is to supply one hive with brood and honey from one or more others, then the contents taken from that one hive is put down as a *bonâ fide* gathering by one hive. Let every hive perform its own duty except in doubling swarms, which it is more profitable to do when there is honey to gather than at the end of the season to preserve alive bungled and otherwise mismanaged stocks. Bees are not worth keeping unless every hive can gather a

surplus, and this they will do if kept in large hives and have anything like favourable weather during the honey season.

Still another thing you must guard against, also taught by some—namely, when the bees are about taking to the supers do not remove part of their combs leaving scarcely half enough for the internal economy of the hive, forcing the bees into the supers, thereby cutting short any chance of a large yield. A case of “killing the goose for the golden egg.” An example in point concerning two clever bee-keepers. It was a bad year with little signs of improvement at the beginning of August. The one hired the other's bees from that time onwards at so much for the super only, all in the body of the hive was to remain for the benefit of the bees. When the hirer of the bees got possession of them he removed all the combs containing honey to about the one-half of what the hive contained in full, in short to six frames of large size, the bees were fed a little to encourage breeding, and were crowded out. Supers were added which the bees took to at once, and the Heather which was in the immediate vicinity was bursting into bloom, yielded honey plentifully, but for a few days only. The supers on these hives were filled, but on no others; these were at once taken off and empty ones substituted, resulting in drawing off the brood through the impoverished state of the hives, and at the end of the season when the extracted combs were returned there were but few bees to take advantage of them, and the season was too far advanced for the bees to better their condition by breeding, while the small sum received for hire was insufficient to purchase bees to make them as good as they should have been.

Moral, always keep your hives strong in bees, and the more empty comb they have during a honey glut, though it be of short duration, the better. I will at another time return to the subject, and give instructions to beginners, hoping the foregoing will help to keep in the right path those who are willing to be led by —A LANARKSHIRE BEE-KEEPER.

#### EARLY SWARMING.

YOUR readers may be interested in the following account of a swarm which came from a straw skep in this neighbourhood a few days ago. It took place about ten days ago, on one of the warm days which we in this neighbourhood had immediately after the frost broke up. The hive was light. The occupants of three hives had been joined together last autumn. Seeing the bees were very busy, the owner was watching them, when suddenly the queen came out. He caught her, and held her in his hand, while he asked a friend who was with him to get an empty skep. He was about to put the queen into this skep, when she flew away, and he expected to see no more of her; but in two or three hours the swarm was found 300 yards off on an old earthen bank, or dyke as we call them. It was duly hived, but was returned to its old home. What, however, struck the man as peculiar was that when the queen escaped from the hive he saw nothing in the shape of a swarm following her, and the remaining bees seemed to go on just as they had done before gathering bee bread, and he could not see any reduction in their numbers. The swarm was about the size of a cocoa-nut. —A BEE-KEEPER IN DUMFRIESHIRE.

#### TRADE CATALOGUES RECEIVED.

Viccars, Collyer, & Co., Leicester.—*Catalogue of Seeds and Specialties.*  
Jacob W. Manning, Reading Nursery, Reading, Mass, U.S.A.—*Catalogue of Fruit and Ornamental Trees, Shrubs, and Herbaceous Plants.*  
Charles Turner, Royal Nurseries, Slough.—*General Spring Catalogue, 1886.*  
William Paul, Waltham Cross, Herts.—*Catalogue of New Roses, &c.*

\* \* All correspondence should be directed either to “THE EDITOR” or to “THE PUBLISHER.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Royal Botanic Gardens (*Old Gardener*).—If you write to W. Sowerby, Esq., the Secretary, he will inform you of the manner in which Fellows are elected, these alone, we believe having regular admission to the Gardens.

Mrs. Pearson Grape (*J. F. H.*).—This variety was raised by Mr. Pearson at Chilwell from Black Alicante crossed with Ferdinand de Lesseps, and was awarded a first-class certificate by the Royal Horticultural Society in 1874.

White Chrysanthemum for Market (*D.*).—The following varieties are extensively grown for the sale of their blooms:—Madame Desgrange, early, followed by Elaine, Lady Selborne, Mrs. G. Rundle, Mdle. Lacroix, White Princess of Teck, Meg Merrilies, and Miss Marechaux, these affording a supply from September to the end of the year under good management. We are unable to answer your other question.

Lapageria Sporting (*G. H.*).—We see no reason why the sport you describe should not be fixed by pegging down the branch in turfy peat and sand, and rooting it as a layer. We are not able to say how far your variety is distinct from others without seeing a flower.

White Flowers for Wreaths (*T. A.*).—The following are amongst the best and most generally used plants for supplying flowers for wreaths:—White Azaleas, Camellias, Roses, Carnations, Pinks, Chrysanthemums, Lily of the Valley, Spiræa japonica, Roman and Dutch Hyacinths, Tulips, Epacris, Begonias, Callas, Bouvardias, Gardenias, Eucharises, Stephanotis, Paper White Narcissus, Rhodanthe maculata alba, Ammobium alatum grandiflorum, White Double Pelargoniums, Lapageria alba, Achilleas, Gladiolus The Bride, Gelder Roses, Lilacs, Chinese Asters, Lilliums, Freesia refracta alba, and Hellebores. If you do not know the best of the Azaleas and such plants and write to us again, we shall be pleased to help you.

Wanted Vine Roots (*Phylloxera*).—We regret to inform you that there is no doubt as to the presence of the phylloxera on the Vine roots you have sent. This insect passes through various stages, those now present being in what is termed the nymph form, and will speedily develop if permitted to do so. You may if you like saturate the border with ammoniacal liquor from gasworks, half-diluted. This proved effectual in a garden at Eaton Hall; or you may prefer to adopt a more radical method of extirpating the pest. The leaves sent are perfectly clean.

Beetles in Vinery (*J. M.*).—Your house is infested with the Vine weevil *Curculio Betuleti*. It is seldom we hear of this pest being found in such great numbers, as you appear to have caught over a thousand during three evenings. We know of no easy means of extirpating the pest, which is very destructive and feeds at night. You had better continue your practice of searching for and catching the weevils, and the house and Vines must undergo a radical cleansing in the winter. You may try the effect of the hellebore and petroleum mixture, as recommended to another correspondent, and we shall be glad to know if it proves of any value in your case.

Grafting Weeping Ash (*J. H.*).—You may graft your young Ash trees with weeping varieties at once. If the stocks are moderately strong at the top place a scion on both sides. The scion should be put on with the growth buds upwards and not downwards, for it is natural for the growths to weep without the adoption of such artificial means as the reversal of the scions. The scions should be from 2 to 3 inches in length, half or little more of that length being cut in a slanting direction with a sharp knife, a similar piece should be removed from the stock, and the two cut portions made to fit exactly. This done, and made secure, a little clay or grafting wax should be well rubbed into the tying material used, and then the whole covered with sufficient to exclude air. If clay is used a good percentage of cow manure should be incorporated with it to prevent it cracking by the influence of drying winds.

Pruning Orange Trees (*M. R. D.*).—We should not hesitate to prune the trees now to any desired extent, but the exact extent to shorten the branches can only be determined by the condition of the trees. After pruning they should be syringed twice or thrice a day to excite the production of fresh growths in preference to keeping the roots in a very wet state. If these are healthy your shoots will push from the old stems in a house in which a genial atmosphere is maintained. You may cut down the Shaddock to the strong growth on the lower part of the stem, or shorten the upper branches according as it may be thought desirable. A definite opinion cannot be formed in a case of this kind without inspecting the tree, and you had better confer with a good practical gardener on the spot. We suspect the authors of the evil are liable to damages, but it is not always easy to prove allegations of the nature indicated.

Grass Seeds for Embankment (*Cranfordian*).—For so small a plot of ground it is not practicable to apportion the quantities of the different varieties of Grass seeds that would be suitable for the purpose intended. The mixture should consist of such kinds as *Cynosurus cristatus*, *Festuca duriuscula*, *F. rubra*, *F. tenuifolia*, *Poa nemoralis sempervirens*, *Trifolium minus*, and *Lotus corniculatus*, with *Lolium perenne tenue* to shelter the finer Grasses until they became established, and so insure a quicker and better lawn. We should procure 3 lbs. of the finest mixture of lawn grass seeds—i.e., finest Grasses and Clovers, from a respectable seedsmen, and having the ground in fine tilth sow about the second or third week in this month (April) on a calm day evenly, raking over lightly after sowing, and passing a roller over the ground, or otherwise making it even and embedding the seed in the soil. It is better if a time be chosen for sowing when there is an early prospect of rain.

Caterpillars in Vinery—Hellebore Petroleum Mixture (*S. Carlisle*).—The specimens shall be examined, all we can do at present being to suggest a remedy that we have found quite effectual in the case of the Gooseberry caterpillar and many other garden pests. We put 2 ozs. (a small wineglassful) of petroleum, 2 ozs. of soft soap, 1 oz. of washing soda, and 2 ozs. of hellebore powder into a two-gallon stone bottle, and pour in one-gallon of boiling rain water over them; shake violently, let it remain till cool, then strain through a cloth. This applied with a syringe destroys all caterpillars it touches and does not injure the trees nor stain the foliage. In the case of very tender plants, or of leaves covered with fine hairs, it might be prudent to try half the quantity of petroleum, but more than that.

named does no harm to smooth leaves. We advise its use during the evening, soon enough for the Vines and plants to get dry before nightfall, as the action of the sun on the wet foliage may cause injury. Still as much depends on the effective preparation of the mixture, you had better try it on one or two plants and parts of a Vine, noting its effect before syringing the whole of the Vines and plants.

**Lengthening Lawn Tennis Ground (Merchant).**—The lower part of the ground will no doubt consist of good soil, and that would be best removed and placed handy for covering any rubbish you may bring in to raise the ground. You may fill up with cinders or any other description of rubbish until you get within 2 feet 6 inches or 3 feet of the intended surface, and that should be good soil for insuring a good growth of grass, and a similar thickness should be present on the face of the embankment for the satisfactory growth of the shrubs. We do not consider Rhododendrons suitable for a steep slope. Laurels would be better, and, pegged down, would have a neat appearance, besides helping to keep the bank up. Even with common Laurels pegged down you will not be able to have so steep a slope as if it were turf'd or covered with Ivy, but the best form of slope is that having a base double that of the height. For instance, if you raise the ground 2 or 3 yards, the width of the base of the slope should be 4 or 6 yards respectively. This is very much better in every respect than a steeper slope, indeed it is as steep as it ought to be for planting with shrubs. The mode of levelling the ground is right—i.e., level it with pegs to the extent required from the present ground to which it is to be a continuation. In putting in the materials they should be well trodden down or rammed so as to prevent their settling. If you have the ground asphalted or cemented cinders would be far the best material, ramming them well down. At the end, instead of a slope you could have a retaining wall, but a slope planted with common Laurel would be the most pleasing. If you have a retaining wall it should incline inwards about 1 foot in 9 or 10 feet of height. Drainage will not be necessary if you use rubble, and certainly not if it be cemented. Asphalt is not suitable, as the smell of tar is not pleasant for a long time after making.

**Destroying Ants (Liverpool).**—If the ants have their nests in the open ground where they can be got at readily, a dry time should be selected, hollow out the nest so as to form a cavity, and pour into it a solution of Fir tree oil insecticide at the rate of a pint to a gallon of water at a temperature of 100°, or if there are no plant roots it may be applied at any temperature between that and boiling. The ammoniacal liquor from the gasworks is also useful. It may be applied where there are plants growing diluted with six times the quantity of water. Gnano sprinkled over their nests and haunts will drive them away. If the ants have their nests in plant houses or where the above cannot be applied, the best plan we know is to get some pieces of sponge, the coarser the better, and dip them whilst squeezed in the fingers in a vessel containing honey or treacle, withdrawing the pressure the honey or treacle will be absorbed into the interior of the sponge. Place these as baits on pieces of slate or plates, which will attract the ants, and when a good number have entered the pieces of sponge they may be thrown into a pail of boiling water. Wash the sponges clean in warm water, dry them, and repeat the bait. They may also be poisoned by mixing honey and arsenic together, but it must be thoroughly mixed or the ants will take the honey and leave the arsenic. It must be used with great care. Half-picked bones are excellent baits. Petroleum is a good ant eradicator. A lump of camphor the size of a Filbert dissolved in a quart of water and this applied, has been found effectual without injuring the roots of plants. We give a choice of remedies, so that if one fails or is inapplicable in any particular case, another may be tried.

**Cyclamens (J. H. Y.).**—Many gardeners fail in growing these plants satisfactorily, not from want of skill so much as by lack of suitable conveniences. The finest examples are produced in low heated span-roofed houses wholly devoted to these plants, the pots standing on a close moist base, not dry open stages, and a genial atmosphere maintained, the night temperature being about 60°. They must have all the light possible, yet shade from bright sun, as if this extracts the moisture from the leaves more rapidly than it is supplied by the roots the plants cannot be satisfactory. They succeed well in frames in the summer with good attention as regards watering, syringing, shading, and ventilating. Mr. Hugh Ranger, an admirable grower of Cyclamens, read a paper on their culture at Liverpool. This was published in the Journal on page 541, December 18th, 1884, and as the number is out of print we cite the following:—"Cyclamen persicum and its varieties may be had in flower from the beginning of September until the end of March, or even the end of April. In order to grow them successfully very careful treatment is required. The seed should be sown in September in shallow seed pans, and the pans placed on a shelf close to the glass in a warm greenhouse or cool stove, where the temperature will be about 60°, shaded from the sun, and the soil kept constantly moist. The seed will germinate in about six weeks, and as soon as the first leaf is developed the seedlings should be placed singly in 2-inch pots, and still kept in the same temperature close up to the light, but shaded from the sun. They may remain in these pots until the beginning of February, when they should be shifted into 3½-inch pots, and still kept in a similar temperature, and sprinkled occasionally in the mornings of bright days; and as the season advances the young plants will make rapid growth, which must be encouraged, and great care must be taken to avoid giving them a check in any way. The plants will do in these pots till about the beginning of June, when they may be placed in warm pits for ten days or a fortnight, and then transferred into 5 or 5½-inch pots. After potting they should be kept close, syringed, or sprinkled with a fine-rose watering can, and shaded for a time until the roots have taken to the new soil, when air may be admitted freely. They should still be shaded from the sun, syringed twice a day, and the house closed at night. The larger size pot will be a good one to flower them in, but if extra large plants are required the best and largest of them may be potted again about the end of July or the beginning of August, this time into 7-inch or 8-inch pots. By the end of October the plants in the smaller pots will be 10 inches across, and those in the larger pots 15 inches across, carrying from 100 to 200 flowers each, provided the plants have done well. Thus by following the course I have indicated, Cyclamen persicum can be grown 15 inches in diameter in thirteen months from the time of sowing seed. To flower them well they should be placed in a light airy house with the temperature from 50° to 55°. The soil I have

found to suit Cyclamens best is a mixture of three parts good fibrous loam, two parts good leaf mould—the latter not too much decayed—and a sprinkling of silver sand, with the addition of a little Clay's Fertiliser, say a 5½-inch potful to a barrowload of the compost." The plants must be kept scrupulously free from insects, or the best of soil will not avail to produce good flowering plants.

**Notes on Bee Management (A. S.).**—We are obliged by your letter. You will find something of what you require in this issue of the Journal, and more plain notes will follow. If you desire specific information on any particular point, and state your requirements from time to time, your letters shall have attention. That before us now appears to embody general suggestions pertaining to the whole routine of bee-keeping, and the various points indicated are not likely to be overlooked.

#### CLOVER AND GRASS.

RED Clover sown annually with a corn crop is a part of the old four-course shift to which many a farmer still clings with characteristic persistence, and there is undoubtedly

strong reason for doing so. Good clean seed sown in April seldom fails to afford an abundant plant, and in the following year the crop is turned to account in several ways. It may be used entirely for grazing; the first growth may be cut green for forage or mown for hay just as the plants come into flower, and the second growth may be fed off by sheep in folds, or be kept for seed. In a favourable season the saving of the second crop for seed answers very well, a high price often being realised for the seed: but in such a cold wet autumn as we had last year much of the seed was spoilt, and sheep-folding answered best. Regarded from the safe aspect of general utility solely as a forage crop, Red Clover alone is not a desirable crop, and it is fast being replaced by a mixture of Clover and Grasses, as affording more certain results and a heavier bulk per acre. In such mixtures Cocksfoot, the best of all our perennial Grasses, now takes a leading place with the best of the Rye Grasses, and we certainly have reason to prefer it to the ordinary mixture of Clover and Rye Grass. Mr. Ashton, the winner of the first prize in the farm competition of the Royal Agricultural Society last year, goes a step farther than this, and has two-year layers, for which he uses twelve kinds of seed at the following rate per acre:—Half bushel each of Pacey's Perennial Rye Grass and Italian Rye Grass; 3 lbs. each of Red Clover, Cow Grass, and Alsike Clover; 2 lbs. each of Timothy, Cocksfoot, Crested Dogtail, and Rib Grass; 1½ lb. each of Trefoil and Giant White Clover, and 1 lb. of Sweet Vernal. The Judges mention in their report that: "In this Mr. Ashton's practice differs widely from that of many of his neighbours, who sow a mixture of Red Clover and Italian Rye Grass only. Nothing, however, could be better than the well-mixed hay produced on this farm in almost every case." The bulk obtained per acre must be remarkable, for they say farther: "In April the first cutting to sell green was just commenced, and in July it was ready to cut again, and will be cut a third time this summer, so we were informed. Following his usual practice, Mr. Ashton top-dressed this piece, after the removal of the first cutting, with sawdust-manure soaked with liquid manure, which was pumped on to it in the midden from the tank into which the buildings are drained."

We mention this part of Mr. Ashton's practice because it is in keeping with the sort of high farming we advocate and practise, and we may usefully follow the report of his practice and its results a little farther. We are told of a piece of first year's seeds being cut for grass, which was a heavy crop of the best quality. The earliest cut from the first year's seeds is secured by sowing a few acres each year early in the autumn, after Tares or early Potatoes. In the first year three green cuttings are usually taken off, and in the second year the seeds are twice cut for hay. "The first cut of grass should yield about 12, the second 7 or 8, and the third 9 or 10 tons per acre; and the second year the first hay crop will probably not be less in a favourable season than 2 to 2½ tons, and the second crop from 1½ to 2 tons." We here quote the exact words of the report in order to authenticate this extraordinary statement, which we do not in any way venture to question, for we know in ordinary practice it is quite customary to sell the first cut of green forage at 1s. a perch or £8 an acre, and under a spirited system of high farming we may fairly expect a first crop of mixed Grasses and Clover of 12 tons an acre, worth £1 per ton.

Eastern county farmers have recently been invited to consider the advantages of permanent pastures, but a tenant farmer might turn his attention more advantageously to alternate husbandry, and while avoiding the annual sowing of Red Clover follow the happy mean of two or three-year layers of mixed Grasses and Clovers. He would thus avoid the double expense involved in laying down land to permanent pasture, as well as that which one-year layers involve, and he would enjoy a quick and profitable return upon his outlay. No doubt farmers near large towns have exceptional advantages in the sale of such crops, but no really clever

farmer could be at a loss what to do with them wherever his farm might be.

The existing prejudice against hay made from strong-growing Grasses on the score of coarseness is taken advantage of by dealers in hay. It ought now to be known generally that chemical examination and careful observation of their effect on stock show that the Grasses which are most productive are also the most nutritious. Cocksfoot, which is the most robust of all the permanent Grasses, is pronounced by our highest authority, Mr. Faunce de Laune, by far the most valuable of all Grasses, because it grows in all soils; it produces the greatest amount of keep; it is the most nutritious Grass, and seems to grow faster and stronger in extremes of weather, either wet or dry, than any other Grass. There is, moreover, hardly any stage of its growth in which stock do not eat it greedily. We have at the present time a rick of hay in use consisting entirely of Cocksfoot and other coarse Grasses, and we have every reason to be satisfied with its quality and its effect upon the stock.

#### WORK ON THE HOME FARM.

On every hand may be seen the almost magical effects of genial spring weather upon vegetation. Winter corn has lost its russet hue. Grass, too, grows apace, and we have been able to take ewes and lambs out of the Turnip folds on to the pastures for a few hours daily. Eagerly do they eat the young grass, and we are glad to say it has failed to produce any signs of scouring; but then the ewes have plenty of chaff, cake, Oats, and bran in the troughs, and the lambs have as much mixed lamb food as they can eat. Printed instructions were sent us with the first consignment of this food, as to how much weight of it we were to allow each lamb daily. While ignoring this well-meant advice, we told the shepherd only to use a small quantity at first, and to give more as the lambs appeared to require it. The condition of the lambs is highly satisfactory, and we now think we shall be able to send some early draughts of fat lambs to market. Our bacon pigs sold well, exceeding our average of £4 apiece; some of them ranging as high as £5 5s. On the whole our venture in winter pigs has answered, and our inferior corn has been profitably turned into pork. Early litters of spring porkers suffered from the effects of cold weather so much that many were lost. We shall, however, muster enough for our purpose, and we always find six or eight pigs to a sow more profitable than double the number. Winter Tares sown late in November could hardly be expected to answer, and our advice to an amateur farmer who complained of the failure of his efforts to obtain a crop in that manner was to sow spring Tares at once. We never had but one failure of winter Tares, and that was owing to having sown them in September: they were too forward and perished. The nitrate of soda sown upon the Rye was quickly dissolved by rain, and its beneficial effects are already visible, the growth being quick and strong. It is nevertheless backward, and glad shall we be when we are able to begin folding the ewes and lambs upon it. A moderate supply of roots and backward spring puts a strain upon farmers' resources, evidence of which may be seen in the guise of the large numbers of hoggets in poor condition now forced upon the market. Our preparations for root crops are in a forward condition, and the Mangold crop will this spring be sown soon after the spring corn. On heavy land the work of sowing has been much hindered by rain, and while one of our bailiffs has been able to point to corn-sowing finished, another had not got through more than half of it at the same time. By the exercise of a little patience and perseverance difficulties of this kind will soon be overcome, and we may reasonably hope for early seed-germination and quick growth now.

#### REMARKS.

28th.—Dull and showery.  
29th.—Wet early, dull till 10.30 A.M., afterwards sunshine and showers, with high wind; clear at night.  
30th.—Fine and bright till 11 A.M., heavy S.W. gale with showers all day and night.  
31st.—Generally bright, with showers; gale unabated.  
1st.—Fine and bright.  
2nd.—Bright early, afterwards dull and showery.  
3rd.—Rain early, but generally fine and bright.  
A mild week, with only one trace of frost; hot sun on sever days.—G. J. SYMONS.

### PROFITABLE GARDENING.

**T**HERE are hundreds of practical gardeners out of employment, and many thousands of dwellers in towns very badly supplied with vegetables, fruit, and common flowers, and those who have the welfare of both classes at heart may well set the former to work to supply the latter. Not a few gardeners have invested their "all" in florists' businesses and small nurseries, only to find that in most districts there were already too many. Others have hired or built several forcing and plant houses, with perhaps a little land attached, with the idea of making a fortune with the profits attending the sale of fruit and cut flowers in the London markets; but these again, unless they are particularly keen and practical, are doomed to disappointment and failure. There are by far too many labouring to supply the principal markets, notably Covent Garden, and the sooner innumerable private gardeners as well as others beginning on their account realise this fact the better for them and those whom they serve. It is the small towns that as a rule are badly supplied, and it is among the middle and working classes that customers are to be found.

I do not advise any gardener at present in a fairly good situation to exchange this certainty for what might prove an uncertainty, but were I out of a situation I would unhesitatingly commence on my own account, and most probably in this neighbourhood, where there are already several well-established market growers. As a rule the men that at present monopolise the business of small towns are greatly inferior in ability and general experience to the majority of the very men now struggling on, charitably employed it may be by various nurserymen, and waiting for head places that seem farther off than ever, and yet the former prosper simply from the fact that they are plodding and were content to make a small beginning. Now that the craze for building has subsided with no prospect of any immediate revival, much less difficulty is experienced in obtaining land comparatively near to a town than many seem to imagine, especially if one would be contented with a moderately long lease. Then, seeing how easily money can be borrowed, it is decidedly a mistake to wait till such times as enough can be scraped together for a big commencement. There is no time like the present for commencing, everything, including uncultivated land, manual and horse labour, being plentiful and cheap, while houses can be built at a surprisingly cheap rate, and when a revival does take place the market gardeners will be the first to feel the reaction in the shape of a greater demand and better prices.

It is a well-known fact that in spite of the poorness of the prices obtained by the senders to large market towns the inhabitants are rarely supplied at a proportionately cheap rate, or otherwise there would be a much greater demand, both growers and consumers being benefited accordingly, but sooner or later I hope these rapacious middlemen will come to grief. Even greengrocers and fruiterers in small towns

have to be watched very closely, and many of these must have everything for about half its value, even if there is little or no risk of its being unsold. If it is not possible for a beginner to open a shop for the sale of fruit, flowers, and vegetables, then the next best thing is to arrange for the regular supply of all that may be needed by a certain number of hotel-keepers, tradespeople, and other well-to-do people who have no garden of their own. The smaller greengrocers will usually take all that may remain to be sold. This is no imaginary scheme, as I have been repeatedly asked to supply townspeople, and I am acquainted with several private gardeners who have long been obliged to sell surplus produce, and these men now have their regular customers. In one instance three private families are supplied with everything but Potatoes from one garden, and the plan works well all round.

It is unwise to depend solely on a vegetable and fruit garden for gaining a livelihood now-a-days, as what is wanted is something of everything and not too much of a few things only. There are customers for all the surplus produce except those high-priced of private gardens, as well as that grown under glass and in the open by market growers. At the outset I intended to point out what I find pays best for growing, but as I have occupied much space in expressing my views on this important subject of how best to utilise the talents of many good yet unemployed men, I must at present confine my remarks upon the profitable cropping of the open garden, leaving choice flowers and fruit for another occasion.

As before stated, high prices are seldom realised, and the aim should be to crop the ground as closely as may safely be done with the kinds of vegetables, fruit, and flowers that may be most in demand. Supposing there is a warm end or corner, it is here that the most scheming is required. There should be good breadths of Ashleaf Potatoes, Kidney Beans, notably Ne Plus Ultra and Canadian Wonder; Lettuces, preferably Paris White Cos; Nantes Horn Carrots, with Radishes everywhere. The latter are sometimes very profitable, as they can be sown over the Potatoes among the Carrots in advance of the Beans and various other crops. Wood's Frame and French Breakfast are the two best sorts, and hundreds of bunches at 1d. per bunch or thereabouts may be quickly and profitably grown. Lettuces again may be grown by hundreds or thousands (we have already put out two thousand) on the ridges between the Celery rows, on young Strawberry beds, and other positions, and if only 1s. per dozen is obtained they pay well and quickly. The Brown Cos, though one of the best sorts for a private place, is unsuitable for marketing. Neither do the buyers care for the Cabbage varieties unless there is no choice in the matter. Early Turnips are profitable, and an east border as well as spaces between fruit bushes may well be sown with Early Milan and Snowball, the latter in the greatest quantities. During the summer and early autumn months there is much less demand for Turnips, but for the winter supply it is advisable to sow a good breadth of ground, just cleared of early and second early Potatoes, with Veitch's Red Globe Turnip. Nantes Horn Carrot is always profitable, so many bunches being drawn from a comparatively small piece of light ground. It is also good for the winter supply. Onions, very small in bunches and fully grown, usually pay well, and so also does Beet. The former ought already to have been sown, but Dell's Crimson Beet, the best for all purposes, may be sown any time in April or early in May. Celery we cannot grow enough of, and really good, not necessarily large, samples will, I believe, sell anywhere. There is no demand for early Celery, November, December, and January being the best months for it, and at 2d. per stick, or even less, it pays very well. We prefer Williams' Matchless and Leicester Red, good substitutes being Sulham Prize and Carter's Incomparable Crimson.

Very early and late Peas do not pay; but a few rows of

William I., followed by Telegraph or Telephone, the two latter being staked, usually prove remunerative. William I. may be profitably grown on open ground without stakes, as well as Pride of the Market, Dr. McLean, and Veitch's Perfection. Runner Beans are always in demand, and when they are to be had French or Dwarf Kidney Beans will not sell. They may be trained up stakes any height from 3 feet to 12 feet, or may be grown without stakes, in which case all running growth must be kept closely pinched off. Our rows of staked Beans are disposed 6 feet apart, and the stopped rows 3 feet apart. Between the former we grow two rows of Ash-leaf Potatoes and one row between the latter. Brussels Sprouts are always profitable, and a good breadth of the Aigburth should be established early. Broccoli must be classed as doubtful, though on firm good ground, in succession to early Peas and Strawberries, they are usually hardy and good. Savoys and Kales may be grown as successional crops, being planted between Potatoes. Asparagus, Rhubarb, Seakale, and Mushrooms are always saleable and profitable. There is only a small demand for Globe and Jerusalem Artichokes, and Parsnips do not always find purchasers; but well-grown Horseradish is bought readily, and the same may be said of early and late Parsley. Early Cabbages only, and Veitch's Autumn Giant Cauliflowers prove remunerative hereabouts, the former in succession to Onions and the latter between or after early Potatoes.—I. M., *Somerset*.

### POLYANTHUSES FOR CULTURE IN POTS.

At the outset I must explain that I do not mean the florists' gold laced varieties, but those strains of mottled, self-coloured, and white varieties which have been advancing with such rapid strides during the past ten years. You printed a short note on these which I sent you about twelve months ago, and I then detailed the method of growing them which has given the finest plants. However, in drawing attention to the place which these beautiful flowers may be made to fill as decorative greenhouse plants throughout the early spring months, it may not be amiss to give a résumé of the cultural details.

In the first place seed should be sown at once, or if deferred much later it will be better to sow in boxes and raise the plants in a cool house. In preparing the seed bed it should be made rich with some light root-producing material, of which spent Mushroom bed refuse is a very good example. This is not dug into the soil, but is spread over the surface of the beds after the ground has been dug, and is then mixed with the surface soil to the depth of 2 or 3 inches. Treated in this manner the seedlings have something which they can take to from the first. If good plants are expected—and unless they are strong they are of no use for pot culture—the seedlings must be transplanted before they have made much growth into a specially prepared bed. I find it useful to have a piece of ground set apart for the growth of various plants. This ground has a hard bottom of coal ashes, and in preparing a suitable bed for Polyanthus a portion of this cinder-bottomed ground is chosen of a suitable size. On the cinders a layer 3 inches deep of spent Mushroom manure is firmly pressed down, and on the manure a surfacing of loam and manure, in the proportion of two of the former to one of the latter. This is also made quite firm. The seedlings are on the first suitable day after the bed has been made up—a drizzly damp day is best—pricked out in rows 9 inches apart, and about as much apart in the rows.

After attention consists in giving water as it may be required and keeping them free from weeds. In October the strongest plants are lifted and placed in pots, the precaution being taken ten days before the time of lifting to cut down each row and between the plants in the rows with a spade. When lifted the plants will have capital balls of active roots, and should be showing a number of trusses ready to throw up on the first exciting cause. If the plants can be kept in a cool light structure, and not allowed to be frozen, they will continue to progress slowly through the winter. A little heat does not hurt them if carefully managed; a very good guide to follow with this and kindred subjects being to take the average temperatures of the season they flower out of doors, and falling a few degrees to make up for the want of air which they more or less have to put up with when grown under glass.

When well grown these free-flowering strains of Polyanthus form quite a feature throughout the spring months, and well repay the care spent in bringing them on. I have found them very popular, and on the whole of much service. Primroses, though useful, I do not find to be so floriferous as Polyanthus. At the same time they are well worth growing, the cultural details being the same for both plants.

It may be noted that seedling plants are better than sorts which have been selected, named, and propagated by division. However, as some of the named varieties are quite indispensable, and some seedlings may be so good as to be worthy of growing on in future years, it is necessary to treat these so that they keep in robust health. In our soil we have the greatest difficulty with these, and when kept in pots the plants are very apt to be neglected, so that we would advise a like treatment to be given these as already advised for seedlings. Double varieties require to be dealt with in the same manner.

A word of caution may be given as to purchasing named varieties. I have had both Primroses and Polyanthus sent with names and only fit for the rubbish heap. Doubtless the vendors would think them worthy of naming, but until both plants are better known than they are at present new growers will do well for themselves to be sure of what they are buying before investing in many named varieties. A variety which it is almost impossible to obtain is the true double crimson. It is most difficult to keep, and in trying to obtain it I have found the best way to proceed in making a purchase was to ask for a bloom from the would-be seller, and in most cases the bloom forwarded has not been the true variety. Beside an inferior crimson, various shades of purple are sold for the old crimson. It is remarkable how many double sorts there are. I have met with two white double, several yellows, three shades of lilac, several purple shades, beside a few intermediate colours. Of Polyanthus we have only two doubles, one almost black and the other an edged variety.—B.

### MELONS.

I HAVE read with interest the able articles upon Melons that have appeared recently in the Journal. I also have grown a few for the past two years in a simple manner, a brief description of which may interest some of your amateur readers.

Two years ago my employer was offered the use of a lean-to greenhouse, 24 feet by 10 feet, adjoining the garden here, but belonging to an unoccupied house. Not knowing how long it might be in our hands, I did not increase my permanent plants, but decided to grow a few Melons in summer, with Chrysanthemums, bedding plants, &c., in the winter. The house in question has very deep front lights (4 feet) resting upon a wall 18 inches high from the ground line. It is heated by four rows of 3-inch piping along the front, about 6 inches above which is a stage 18 inches wide, on a level with the wall plate; a path 3½ feet wide runs parallel, and a stage leaning to the back wall completes the house. On the front stage I grew the Melons, fixing boards 9 inches wide to keep in the soil, and a layer of leaves to prevent it falling through amongst the pipes. On the 12th of May I closed the house, putting in the soil to warm, and on the 13th put out the plants which I had grown on in a frame. For about ten days I employed the fire gently to give them a start, after which I discontinued it except on a few cold wet days. Air was admitted carefully, the house was closed early with a good syring (excepting when the plants were in flower) running the heat up to 100°, sometimes 110°. On several occasions at six o'clock in the morning the glass stood at 57°, but generally about 62°.

The plants grew vigorously, not making large leaves, but solid, and I was never troubled with either red spider or canker. I top-dressed them twice, and the depth of soil at finish was 8 inches. From eight plants I cut nineteen fruits weighing from 1½ lb. to 3¼ lbs. Hero of Bath and Hero of Lockinge produced my largest fruits, Earl of Beaconsfield the smallest, but one of which my employer pronounced the best he had ever tasted. The dates are from a diary of 1884. Last season I was a little later.—J. CORSON, *Down Ampney*.

I HAVE read with much interest the two excellent articles on Melons by Mr. Bardney (pages 206 and 245 of the Journal), particularly his reference to the disease called "rot." I agree with your correspondent in attributing low temperatures as the cause of this evil.

Several years ago the glass department over which I had then charge included the Melon pits, in one of which the plants were affected by this disease in a very striking manner. The Melons were planted in the usual way. The soil was ordinary loam, with a small addition of horse droppings, and was pressed quite firm. After planting, I received orders from my superior to guard against strong firing, to give abundance of air on all favourable occasions, to aim at a slow sturdy growth, as he said they were in the habit of growing too strongly and going off. Under this treatment—the weather being mild—they made rapid progress, but were still very soft. To prevent, as we thought, further grossness, the fire heat was reduced, and bottom heat dispensed with. A few days more and they were at the top of the trellis, being trained on the single-stem system. At this stage they appeared very healthy, which led some visitors to remark that they were the best they had ever seen. Had they favoured us with a visit about a week or ten days afterwards they would have beheld the sad spectacle of nearly all the plants they admired so much being carried to the rubbish heap, as in a few days the stems "melted away," turning quite soft from top to bottom, and consequently causing the collapse of the whole plant. Although we knew that over-grossness was the cause, we did not know how to prevent it in this particular house, as they did very well in other houses. Since then my experience has taught me that the cultural treatment adopted in the above case to prevent the disease was in reality the cause of it—too low a temperature and too much moisture.—D. B.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 250.)

## CUTTING DOWN PLANTS.

THE system of cutting down Chrysanthemums to render them dwarf and more suitable for decorative purposes has much to recommend it, especially in preparing groups for conservatories or exhibition, as it is seldom that naturally grown plants can be arranged so that they can be readily seen. To obtain plants for this purpose strong cuttings should be struck at the same time and in the same manner as previously advised. Do not top the plants, but train them with one stem. As they are mainly used for grouping, and as they are generally stood closely together when in bloom, 9-inch pots will be large enough for the final shift. If possible the pots should be of one uniform size, therefore after the cuttings are

Fig. 50.

struck place them into 3½-inch pots, and then into those 5¼ inches in diameter, using similar soil to that recommended already, transferring the plants to cold frames as soon as they are ready.

About the 20th of May cutting down should commence with the late-flowering varieties, say for example *Boule d'Or*, *Meg Merrilies*, *Yellow Dragon*, *Grandiflorum*, *Princess Teck*, *Hero of Stoke Newington*, and *Cherub*; midseason varieties about the 1st of June; and the early-blooming varieties, such as *Elaine*, *Mrs. G. Rundle*, and *Prince Alfred*, should be cut down about the middle of June. None should be cut down later than this date if they are to be in bloom early in November. It is well to take into consideration the purpose for which the plants are required in determining the height at which they are to be cut. Dwarf-growing varieties best suited for front rows of groups may be cut down to within about 4 inches of the soil, the others to 6, 8, and 12 inches. As they do not break so freely from the old wood as from the young, plants of small-flowered varieties which are intended to have more branches each should not be cut so low as the larger-flowering varieties.

Great care must be exercised in watering the plants after they are cut down, as they do not require much water at the roots for some time. If they can have the protection of a cold frame so much the better, as they can then be protected from showery weather. Syringe the plants once a day to assist the shoots starting, and if the sun be very hot at this time a little shade in the middle of the day can be applied. As soon as the shoots are long enough to determine if they are perfect, disbud to the quantity required; three branches for most sorts is enough, except the small-flowering varieties which may have five or six. At this stage transfer the plants into the largest pots, and when rooting into the new soil remove them to their summer quarters, allowing them ample space,

as crowding quickly spoils their appearance, drawing them up weakly and ruining the foliage. Tie each branch to stakes separately to prevent their being broken or the leaves damaged by chafing during gales of wind, and as soon as the pots are filled with roots stimulants may be supplied.

The first buds produced on the shoots after cutting down should in nearly all cases be selected as best suited for producing large blooms. They will appear from the middle to the end of August, and it will be soon enough if some sorts show their buds the first week in September, such as the *Queen* family. Sometimes a bud will show the first week in August. This is too early. In this case rub it out and wait till the next one shows, which will be about the middle of September. When the buds are selected take off all growth shoots, which are freely produced at this stage. Commence housing the plants the 1st of October, starting with the late varieties, and have all under cover by the middle of the month. Place them as near to the glass as possible, giving sufficient space to each plant to prevent loss of the foliage. Fire heat will be needed occasionally in dull weather to prevent the blooms damping. Thin wires are useful to support the stems when the plants are required for exhibition grouping, as stakes of this kind are less seen than those made from laths or hazel stems. Another advantage gained by the wire supports over the wooden ones is that sometimes one flower does not come quite in the right place, whereas in this case the wire can be bent as desired.

The illustrations (figs. 50 and 51) show a cut-down plant and one bearing flowers, and will serve to render the preceding explanations more easily understood.—E. MOLYNEUX.

## MR. JOHN SMITH OF KEW.

As will be seen from a paragraph in "Notes and Gleanings," Mr. John Smith, who has been Curator of the Royal Gardens, Kew, for twenty-two years, has, owing to ill-health, resigned an appointment which he has held with much credit. The post is an exceedingly difficult one, requiring a wide practical knowledge together with many other attainments which very few possess; but all who are acquainted with Mr. Smith have had ample proofs that he performed his duties with the skill of an experienced gardener and the courtesy of a gentleman.

Mr. Smith was born in Roxburghshire, and commenced his gardening career in 1841 by being apprenticed to Mr. C. Pillans, gardener to the

Fig. 51.

Duke of Roxburgh, Floors Castle, Kelso. During the three years spent in this garden, which was then one of the most noted in Scotland for the skilful practice there displayed, he laid a good foundation for his after experience. At the end of that period Mr. Smith proceeded to Alnwick Castle Gardens, and he remained in the service of the Duke of Northumberland for twenty years. He worked at Alnwick Castle in a subordinate position until 1855, but the time so spent was most valuable in results, for by his assiduity and perseverance he gained the esteem of his noble employer, who assisted him in many ways. In the year named he went to Syon House Gardens to gain some knowledge of tropical fruit culture, returning to Alnwick in 1856, but was shortly afterwards appointed gardener on the Duke of Northumberland's estate, Werrington Park, Cornwall. Three years later—namely, in 1859—Mr. Ivison resigned the

management of the Syon House Gardens, and Mr. J. Smith succeeded him. In 1864 the curatorship of Kew became vacant, and the appointment was offered by Sir William Hooker to Mr. J. Smith, whose qualifications for the post were well known. Since then he has ably assisted the Directors in maintaining the character of our national garden, and we hope he will long enjoy the retirement he has so well earned.

### HYBRID ORCHIDS.

THE hybrid Orchids obtained within the past forty years constitute an important addition to the number of attractive cultivated forms, no less than 125 having been raised in that period, and the majority are distinguished by characters amply sufficient to command the attention of all who admire this variable family of plants, some like *Calanthe Veitchi* and *Cypripedium Sedeni* ranking amongst the most useful Orchids. The first recorded hybrid Orchid was one observed by M. Weddell on the Continent about 1841, which was described as possessing a combination of the characters of *Aceras anthropophora* and *Orchis militaris*, and was therefore regarded as a probable natural hybrid between those species. As Orchids were then coming much into favour, it is not surprising that some observant cultivators should have given, what proved a difficult matter—namely, a little attention to raising them from seed, and though several engaged in this, it appears that the principal success was attained in the Glasnevin Botanic Gardens, where from 1845 to 1850 numbers of plants were so raised. Dean Herbert also experimented in artificial hybridising amongst Orchids about the same time, but though he states that pods were secured from crossing an *Orchis* with pollen from an *Ophrys*, it does not seem that he succeeded in raising plants from the seed. He, however, mentions having seedling *Cattleyas*, *Bletias*, *Ophrys*, and *Hermidium*. The first substantial results of such experiments were reserved for Mr. Doiny, who commenced hybridising in Messrs. Veitch and Sons' nursery at Exeter in 1853, and first obtained some seedling *Cattleyas*. Owing, however, to the quicker growth of some other seedlings which appeared subsequently, *Calanthe Domini* was the first to flower in October 1856, and was followed by *C. Veitchi* in 1859. About twenty others were selected from others which flowered in succeeding years, and were found sufficiently distinct to merit new names. Since then Mr. Seden has been remarkably successful in Messrs. J. Veitch and Sons' nursery at Chelsea, where large numbers of seedlings have been raised, and up to the present time over sixty handsome hybrids have been flowered and named. It is surprising that amateurs have done so little, for comparatively few have paid any attention to the matter. Amongst those, however, who have made some good additions to the list, must be named Sir Trevor Lawrence, Bart., M.P., Mr. R. Warner, Mr. J. C. Bowring, Mr. J. C. Cookson, Mr. W. Swan, M. Alfred Bleu, and Mr. Cross.

The following list contains all the hybrids concerning which any information could be obtained up to the present time, the seed-bearing parent is named first, and the pollen parent second, in all Mr. Seden's hybrids, and in other cases also where it could be ascertained.

#### MR. DOMINY'S HYBRIDS.

HYBRID.	PARENTS.
<i>Aërides hybridum</i> . . .	<i>A. affine</i> — <i>A. Fieldingi</i>
<i>Anætochilus Domini</i> . . .	<i>A. xanthophyllus</i> — <i>Goodyera discolor</i>
<i>Calanthe Domini</i> . . .	<i>C. Masuca</i> — <i>C. fuscata</i>
<i>Veitchi</i> . . .	<i>vestita</i> — <i>Limatodes rosea</i>
<i>Cattleya Brabantiae</i> . . .	<i>C. Loddigesi</i> — <i>Acklandiae</i>
<i>Devoniensis</i> . . .	<i>crispa</i> — <i>guttata</i>
<i>Domini</i> . . .	<i>maxima</i> — <i>amethystina</i>
<i>exoniensis</i> . . .	<i>Mossiae</i> — <i>Laelia purpurata</i>
<i>Felix</i> . . .	<i>crispa</i> — <i>Regnelli</i>
<i>hybrida</i> . . .	<i>granulosa</i> — <i>Harrisoniae</i>
<i>hybrida maculata</i> . . .	<i>guttata</i> — <i>intermedia</i>
<i>Manglesi</i> . . .	<i>Mossiae</i> — <i>Loddigesi</i>

—LEWIS CASTLE.

## ESTIMATES OF VEGETABLES.

**PARSNIPS.**—These form a profitable crop and do well in almost any soil, but best in that of a deep, moist, alluvial nature; in such the roots are clean and straight, the size being dependant on the ground and the distance accorded the plants. I give 18 inches from row to row, and about 9 inches distance in the row, and secure fine roots. Medium-sized roots are, however, most esteemed for private use, and the kind I find most esteemed is The Student, which has very handsome clean roots, fine quality, and rich flavour. I grew them last year on trenched ground after Peas, and had a crop bringing first-rate returns from the salesman. Under field culture, however, it does not attain sufficient size to please buyers, though for shallow soils it is far the best. Large Guernsey may differ from Hollow-crowned, but it is difficult to distinguish. Hollow-crowned Improved has large roots, the crop being heavy, and taken altogether is the best for general use.

**CARROTS.**—The value of an early crop is considerable, but to secure this warm soils and situations must be chosen. I had a considerable breadth of Early Nantes last year and got an excellent crop, the roots being of medium size, stump-shaped, and coming early to maturity. The colour is a bright red, and that means money. It is the very best of the Early Horn section, and is a selection from the Early Scarlet Horn—an excellent variety, very short small top, but sufficiently large for bunching. James' Intermediate Scarlet affords a capital succession, is of fine shape, and medium size, with fine quality. There are many forms of this best of keeping Carrots, but the most desirable is that with a bright scarlet colour, and strange as this may seem these have firmer, more solid, and sweeter flesh than the pale-coloured roots. These improved forms are all due to selection—seed-saving from the finest quality roots. Long Red Surrey is an excellent Carrot for deep soils, attaining to a large size, and good flavoured. Large Carrots, however, are not in much demand for private use, a medium-sized one being always more acceptable, such are obtained by sowing after a crop of early-lifted Potatoes, and the roots from an early July sowing keep much longer in spring than those obtained from spring sowing.

**BEET.**—The quality is everything in Beet, and this is in proportion to the colour, for the deeper the colour the more tender the flesh, and the higher the flavour, with freedom from woody or stringy matter, so characteristic of the pale-coloured Beets. For private use none surpasses Nutting's Dwarf Red, which is of medium size, red colour, fine quality, and sweet flavour, the top being small. Pine Apple Short-top is also excellent, but does not attain such evenness in growth or size as Nutting's. Dewar's Dwarf Red is of fine shape and good size, and the colour bright red. It is a very good Beet and attains a good size early, and as such is valuable for marketing. Cattell's Crimson attains to a large size, and is not by any means coarse, the colour being good. It is first-rate for market, but colour is

essential, and this it seems to be losing, and points to want of care in selecting seed stock. Black, which is credited with the prefix of its improvers in selection, is in every respect first-rate for market, large and handsome in shape, very dark in colour, and of high quality. This and Cattell's must not be sown early or the plants are liable to run to seed, but sown early in May very fine roots result. Egyptian Turnip-rooted is very useful as an early variety. Beet for late use keeps best buried in the soil on a north border, a protection of straw or litter free from horse droppings being placed on the surface.

**RADISHES.**—For frames there is none to surpass Wood's Early Frame in the long varieties, Scarlet Forcing and White Forcing Turnip, Early Rose Globe, and French Breakfast. They are all excellent, and very fine for early crops outdoors, except in the height of summer, and then if care be taken to water and sow frequently they are the best at that season for private use, where their mild flavour causes their being held in high esteem. Long Scarlet, Red, and White Turnip are the best for summer use, as they stand hot dry weather better than the others, being crisp and of a mild flavour when the early sorts are hot, hollow, and woody.

In Salsafy I do not know of more than one variety, but of Scorzonera there is a great advance in the Russian which is larger and not running to seed so much as the old sort.

**LEEKS.**—Musselburgh is without exception the best, and the giants and others are only selected stocks of this fine sort. Leeks afford fairly good returns, being sown in rows 15 to 18 inches asunder, and 6 inches asunder in the rows. This surpasses the trench, transplanting, and blanching system, for Leeks blanch themselves when properly grown.

**LETTUCE.**—Cabbage for spring use, Hardy White Dutch; summer use, Royal Albert; for frame, Commodore Nutt. Cos—spring and early summer, Bath or Brown Cos, Summer White Cos, of which there are many fine selections, all of the Paris White. Early Lettuces pay well, summer crops do not pay much carriage.

**ENDIVE.**—Batavian Improved Round-leaved and Green Curled Improved. These afford good returns if they can be had in well blanched large heads in winter and early spring, but the foreigners compete keenly with the home grower in early produce, and the shipping and railway companies seem to combine to help them all they can.

**TOMATOES.**—Whether grown under glass or outdoors large fruits with little rib or corrugation command the best prices. The best I have grown is Hackwood Park Prolific. Acme, Dedham Favourite, Hathaway's Excelsior, and Perfection have very fine fruits, all are good croppers and are all after the style of Stamfordian, and in what that differs from Excelsior is not easily observable. Earliness, however, is a consideration, and the corrugated sorts then come to the front, such being Conqueror, Orangefield Dwarf, and Trentham Early Fillbasket. They are harder than the smooth round sorts, and not so liable to split with wet as the round smooth varieties, therefore are better suited for outdoor culture. For the last purpose none surpasses the Large Red, seed being saved from the plants that have the best-shaped fruits, and tend to earliness and prolificacy in the plants.

**SPINACH.**—There is not much choice in this very highly esteemed vegetable, but one sort is worth the other two. How it originated it would be interesting to know, but it grows better and is hardier than the others, and does not bolt or run to seed nearly so quickly, and that means having Spinach in summer. I had it giving large thick dark green leaves this winter when the Prickly or Winter had its leaves parboiled, and it realised 6s. per bushel, when the other gave nothing. It is named Victoria, and well it deserves its name.—UTILITARIAN.

## THE PERILS OF MANURE.

It is the habit of some gardeners to have in an odd corner of their ground a manure heap, which, like certain columns of gleanings we meet with in periodicals, is more remarkable for the promiscuous character of its contents than for their excellence. Often it combines animal and vegetable refuse, earth turned out of flower pots containing fibrous roots, larger roots and stems of decaying vegetables, bulbs, dead leaves, dung, and a comprehensive et-cetera. This is sufficed to remain from autumn to spring; it is then spread upon the soil, perhaps dug in without much preparation or examination. Its condition, indeed, after the moisture of winter is rarely such as to allow of the process of sifting or division by chopping, and unfortunately this half-fermenting pasty substance is likely to be a fertile source of insect life during the ensuing season. I will only mention a part of the enemies of the garden that may possibly be lurking therein, frequently they are at such a stage in their growth that even if the manure be casually inspected they are not perceived.

There will be, for instance, the crustacean woodlice, hiding amid

its damp layers, accompanied probably by one or more varieties of the millipede. Dried leaves or fragments of bark have contributed their quota of carwigs, many small and in that stage when, as I believe, their food is of a mixed character, but still liable to develop until they are mischievous. The brownish bristly grub of the St. Mark's fly (*Ribis Marci*) is a common lurker in manure, and an especial foe to the roots of the Strawberry, but it also attacks many ornamental species in flower beds. That almost omnivorous weevil, *Otiorhynchus sulcatus*, which feeds nearly all the winter, generally finds enough in a manure heap to sustain its life, and completes the larval growth in spring upon whatever plants it can reach in borders. Roots of grass or Clover that may have got amongst the manure will add some wireworms, should they not be otherwise introduced. Another beetle grub that may be secreted in manure is that of the garden chafer or bracken clogs (*Phyllopertha horticola*), which follows the habits of the cockchafer, though fortunately less destructive. Of fly grubs many lie dormant in manure, such as that of the Cabbage fly, the Onion fly, and the Carrot fly, and occasionally, should it be dry, for these pests have no liking for damp, there may be found a winter party of some of the root-haunting aphides ready to propagate during the first mild weather of spring. The process of baking is not applicable to manure, but such a compound as described should be treated, ere using, with gaslime, then exposed to the air for awhile, or with common lime or salt; soapsuds added will kill many, but not all species.—ENTOMOLOGIST.

### CULTURE OF THE NEAPOLITAN VIOLET.

As our system of growing this lovely Violet is somewhat different from that which is generally pursued, we venture to give a brief outline of the method we have found to answer well.

We select a piece of ground upon a south border sheltered on the north side by a wall 10 feet high. The ground is made rich by adding a good deal of decayed manure and chopped turves, a slight dusting of soot being thrown over the ground when the plants are put in. As soon as the plants have flowered they are pulled to pieces, the strongest single crowns are selected for planting. We put the plants into the ground about 12 or 14 inches apart, a good watering is given, and a temporary shade is erected until the plants have got fairly under way. In sunny weather they are syringed once or twice every day in the earlier stages of their growth; during the summer a mulching of horse droppings is given, and the plants kept free from runners. At the end of September, instead of lifting the plants and transferring them to frames, we allow them to remain in their summer quarters, simply putting a board about 10 inches deep around them, upon which the lights are placed. Abundance of air is given on all favourable occasions. By having them so low, and the glass so near the ground level, they are very easily protected in severe weather; mats placed singly over the glass, and a few inches of rough litter spread over the top and around the sides is quite sufficient to keep out any severe frost.

Our limited experience with *De Parme* and the new white Neapolitan enables us to speak highly of both varieties. The former is darker in colour, stronger in habit, and blooms earlier than the old Neapolitan. The white variety grows stronger than the Neapolitan, with large blooms somewhat similar in form to the beautiful variety *Marie Louise*.—JOSEPH OLIVER, *Eslington Park Gardens*.

[We have seen no finer Violets this year than have been sent to us by our correspondent as grown in the simple manner described.]

### SCIENCE IN HORTICULTURE.

In your issue of April 1st, "Young Practicalist" is, to use a common phrase, "running the foreign horticulturist down." I agree with him in some points, but in others I cannot. "Young Practicalist" tells us he has had the misfortune to work with foreigners, and he admits that, as a rule, they are better educated than Britishers in the way of sketching flowers, drawing plans, botany, &c., but when it comes to the practical part of the profession, "Young Practicalist" thinks that our foreign friends are only fit to be classed with beginners. "Young Practicalist" perhaps forgets that if any young British gardener, after working at his profession in England or Scotland from six to eight years, was then to go over to France or Germany, he would find himself farther back, both in practical and theoretical knowledge, than his fellow workmen. "Young Practicalist" seems to think that, as a rule, the British gardener does not require a knowledge of botany or chemistry, to be able to draw plants, sketch flowers, and to know a little Latin; and I will admit that it is not, as a rule, required of us from our employers, but at the same time it is very useful with practical knowledge as well. I think that some of us young British gardeners would find ourselves more to the front if we had a little more "theoretical knowledge," as "Young Practicalist" terms it, and we might devote a little more of our spare time to books and study, also taking more interest in our work, both in working hours and after. An hour or so devoted to study after our work is over for the day would never injure our health nor overtax our brains, although perhaps it might have to be a case of self-denial in something else less beneficial. A man can always be studying when he is at his work, no matter what he is doing. I do not mean to say that a young gardener should be always at work

and study, quite the reverse, for I am a strong advocate of that old saying, "All work and no play makes Jack a dull boy;" but I cannot agree with "Young Practicalist" that if a young man is fond of books and study he loses his liking for work, and thinks himself too good for the practical part of his profession, and in so doing loses the character of being an "active, industrious man."—C. COLLINS, *Howick Gardens*.

PERMIT me as a young gardener of "the period" to have a voice in the question which has lately been having consideration in your columns. Most readers would be apt to suppose, if they were to accept the ideas of "Young Practicalist," that our continental contemporaries are useless men, as he says "they are only fit to work with beginners." That may be true so far, but it most certainly is not true in the sense he gives it. If his opinions are honest, his experience must have been limited. I have worked with Swedish, Norwegian, Danish, Dutch, Austrian, French, and Germans—I do not know if your correspondent can say so much—and I must say that the majority of them are quite the reverse of novices at practice. It is certainly quite correct that most of them have had some academical education, indeed, some I have personally known who have had a university education. Among my acquaintances I have met with the sons of men holding high positions in their own country. As a rule gardening is considered a high-class profession on the continent; indeed, a great percentage of the foreign gardeners to be met with have worked in some of the continental nurseries, and it is well known that many of the new varieties of flowers, fruits, and vegetables have their origin on the continent besides. What "Young Practicalist" says about the pay of British gardeners is right, and I also agree with what he says in reference to science and art as related to practice; indeed, to a certain extent his remarks are indisputable, the chief use of science being to teach us the reason why. Without science our practice is all rule of thumb. I certainly consider that if gardeners are to keep up their reputation some kind of elementary scientific knowledge is indispensable. What would "Young Practicalist" say, for instance, about the late "Single-handed," whose articles in the Journal, I think, were ample testimony of the utility of chemistry? Gardeners, indeed, often outgrow their profession by taking up a science or art, and I could name more than one old or young gardener who are now earning a better livelihood by that means. It has been proposed to add horticulture to the series of subjects of the Science and Art Department. If such an able authority as Mr. Buckmaster were to take the subject in hand, there surely would be few objections in the way. I found my opinions on what the so-called practical men put so much faith in—namely, results. I had the great good fortune to have the opportunity of attending classes connected with the Science and Art Department the first season I was a gardener, and I must say that any gardener who has to do with cropping a kitchen garden will find the principles of agriculture, as far as the analysis of soils and manures, &c., go, to be as useful in the garden as the farm. I would ask "Young Practicalist" how would the superintendents of our various botanic gardens at home and the British colonies get on without some knowledge of botany. I hope I have made my ideas intelligible; there are two sides to every question, and this is no exception to the rule.—R. W. M.

IN reference to the remarks of "Young Practicalist" in your issue of April 1st, page 250, on the above heading, I feel obliged to take exception to some of his statements. It is not my intention to deal with the subject *in extenso*, but to point out what is incorrect and unjust in the second paragraph.

He says, "It has been my misfortune to work with foreigners." This last word, and the pronouns referring to it, should have been in the singular; because, his experience has been with only one foreigner, a young Frenchman from the National School of Horticulture at Versailles, who does not, as "Young Practicalist" "presumes," call himself a "picked foreign gardener." He is one who, after a three-years course in this school, is given a subvention of £50 by his government to spend a year in some establishment at home or abroad, to improve himself in those matters which will eventually be of most use to him. This grant, with his wages, makes him the best paid man among those with whom he works. Therefore the "poser" quoted by "Young Practicalist" does not apply to him.

Then follows the question, "How comes it that the head gardener at one of the most noted places in France will not employ young men from the National School of Horticulture at Versailles?" This I challenge; indeed, I know it to be untrue.

Why I take up the matter is, I annually take a student from this school, each of whom has been a pleasure and a credit to me. The young Frenchman with me now feels most keenly the injustice of the remarks of "Young Practicalist," but cannot so well defend himself in a language foreign to him. Again, as an hon. member of this School of Horticulture, I feel bound to defend it against any unjust imputations as far as lies in my power.

I feel sure if "Young Practicalist" had known more of the National School of Horticulture at Versailles he would not have written of it in the way he has.—A LOVER OF FAIR PLAY.

### LIME FOR VINE BORDERS.

I HAVE read Mr. Bardney's article again on page 104, also his reply on page 189, and think his remarks are liable to be misconstrued. Mr. Bardney seems surprised that I should use lime, but I have only written against what I consider the abuse of it.

Your correspondent says Vines cannot be grown well if bones are

used, but a friend to whom I mentioned the subject tells me he assisted to make a Vine border several years ago. It was composed of sandy turf and inch bones. The turf was used dry, and was well trodden when made up. The border was top-dressed every year with some half-decayed turf and bone dust. Five years after making a trench was opened at the edge of the borders about 2 feet wide, and the whole depth. The trench was again filled with fresh turf and bones, thus keeping the roots in the border and furnishing fresh food. Abundance of water and liquid manure was given, and the produce was good enough to win prizes in first-rate company. I have seen bones used with heavy loam with no perceptible benefit, but with a sandy soil where lime is deficient I believe bones will furnish all the lime necessary.

A writer in recommending fish potash manure confirms my opinion that Vines may be grown with a positive manure, and there is then no danger of the exhaustion which is likely to follow the use of caustic lime. Mr. Bardney's assertion that his borders are rich in humus appears to require explanation when it is remembered he uses 10 per cent. of caustic. "Thinker" points out the usual per-centage of lime in a fertile soil. Does it not occur to him that it exists as carbonate of lime, and not as hydrated or caustic lime? If it is necessary to use a heavy dressing, chalk is better; it is quite as useful to prevent clubbing, may contain a little phosphoric acid, and will not destroy the humus so rapidly. The only cases in which I would use such a dressing of quicklime would be in a newly drained bog, or such heavy land as "Thinker" describes, and even in the latter case I am not sure that burning part of the soil, as recommended by F. H. Cobham, would not have been as well.

"Thinker" and Mr. Bardney say the addition of lime will not cause the loss of much ammonia from the soil, but an experiment I made seems to prove the contrary. I took three tin canisters, punched holes in the bottom of Nos. 1 and 2, put a few crocks in the bottom, and covered them with turf. In No. 1, I put some heavy loam without fibre, containing 10 per cent. of added lime, and covered it with half an inch of loam. No. 2 was not covered. I then filled the canisters with water in which I dissolved sulphate of ammonia at the rate of a handful to two gallons of water. I put the lids on, and in five minutes on taking them off I could smell the carbonate of ammonia, and on a feather wetted with vinegar being held over them a white vapour was given off. No. 3 had 20 per cent. of partially decayed horse droppings mixed with the loam and lime, and after the canister had been covered for a time, the ammonia, although it did not smell so strong, was escaping, as the vinegar proved. Mr. Bardney has evidently a strong prejudice in favour of newly slaked lime, and is consequently unfitted to judge the soundness of my views, but whether the readers of the Journal agree with me or not, I hope they will believe I had no unworthy motive in writing.—A. L. G.

[No one, we feel sure, can question the motives of our correspondent. His object is admittedly to impart information, and he takes pains to ascertain the correctness of his views. This is highly commendable, but Mr. Bardney in recording his experience on page 190 did not say that 'Vines cannot be grown well if bones are used.']

## THE PRIMULAS.

(Continued from page 276.)

*P. SINENSIS*, Ldl.—Although not a hardy Primrose is of sufficient interest to deserve notice here. It may be easily grown by those having a small greenhouse and a little heat at command to assist in raising the seed. It was introduced to this country about the year 1821, and was introduced to Breslau, Germany, by Treviranus in 1826, when the plants were priced at 9s. each, and although called the Chinese Primrose from its first introduction, its native habitat has always been doubtful until Yun-nan was explored by M. Delavay, when it was found growing wild in that locality. It is needless to recount the various and striking improvements that have taken place in this *Primula* since its introduction, the forms being endless, single and double of all forms and sizes; the strains are also numerous. I am unaware of any attempts to hybridise this with some of our less floriferous kinds. There is every reason to believe that something could be done in this way, and although the progeny might not be hardy they would probably stand rougher handling than the type. Syn., *P. pranitens*, Ker; *chinensis*, Lour.

*P. SPECTABILIS*, Thell.—This species, type specimens of which I have not yet seen in cultivation, seems to be very variable. Taking a broad view of it (and you will find intermediate forms to support it), there seems to be every gradation between the very hairy *P. Kitaibeliana*, through *Wulfeniana*, to the large-leaved *spectabilis* and *Clusiana*, the latter apparently the other extreme. In *Wulfeniana* the leaves are pointed as in the type, getting more obtuse with *Kitaibeliana* until they become rhomboid in *Polliniana*. *P. spectabilis* grows from 3 to 6 inches in height. Leaves large, shiny green on the upper surface, obscurely dentate, ovate-shaped, pointed, and more or less erect. The scape terminates in a head of from three to six large deep lilac flowers, surrounded by an involucre of narrow linear bracts. Flowers April and May.

The variety *Kitaibeliana*, Schott, answers in general character to the above, with the exception of the leaves being hairy,

distinctly crenated, and more obtuse. Var. *Polliniana*, Mor.—Almost orbicular leaves, pitted and covered with a transparent glutinous substance. Margins cartilaginous, wavy, irregularly serrated or dentate.

The variety *Wulfeniana*, Schott, is perhaps the best known of the above. The leaves are lanceolate or slightly spatulate, glabrous, shiny green, cartilaginous margins. Flowers larger than in the type, with the exception of *Polliniana*, which is rather difficult to establish. The others may be readily established on rockery. A light free soil mixed with small pieces of granite rock we find suits them well with an easterly or western exposure. Natives of Croatia, Carniola, Austrian Alps, South Tyrol, &c. Flowering April and May.

*P. STEINII*, Obrist.—A hybrid between sub-*minima* × *hirsuta*. It is most nearly related, as will be seen, to the *minima* group, a near ally to *P. Forsteri*, also a cross between the same parents, but super-*minima* instead of sub (after Stein). It is by far the easiest of this group to cultivate; more floriferous than *P. minima*. Generally with a two or three-flowered scape, and not unfrequently flowering twice in a season—in spring and again towards the autumn. It thrives best in a soil abundant in calcareous matter. Much the size and habit of *P. minima*. Leaves in largish rosettes, obovate spatulate, terminating with from seven to nine large teeth, with thinly scattered glandular hairs along the margin. Scape carrying two or three large flowers, violet purple with a white centre; flowering in April. It is found in the Central Tyrolean Alps along with its parents, where it was found in October, 1878, by J. Obrist, of the Innsbruck Botanic Garden, and we believe has not since been found.

*P. STUARTII*, Wall, and *P. purpurea*, Royle, are, in our opinion, the two least satisfactory for garden purposes of all the Himalayan Primroses yet introduced, and according to Sir J. D. Hooker its position seems to be equally unsatisfactory. He says, "This is one of the most common and puzzling of the Himalayan Primulas, if indeed there be not two or more species included under it, with possibly hybrid intermediates. *P. denticulata*, which inhabits lower levels, and *P. petiolaris*, from still lower, are the only equally wide spread and Protean Himalayan congeners. The original *P. Stuartii* was founded by Wallich on a yellow flowered plant, well figured in the "Bot. Mag." t. 4356. *P. purpurea*, published later by Royle (illustrations) t. 77 was founded on a purple-flowered one, which I find it impossible to distinguish by any other character from *P. Stuartii*, the two presenting a parallel series of varieties in the size, shape, mealiness and crenature of the leaves, number of flowers and bracts, and the shape and comparative lengths of the calyx lobes and capsule. *P. Moorcroftiana*, Wall, founded on miserable fragments collected in Western Tibet by Moorcroft, is a third supposed species, which is obviously a small state of *purpurea*. I suspect that all—i.e., *Stuartii*, *purpurea*, *Moorcroftiana*, and *lineariloba*, are forms of the beautiful *P. nivalis*, Pall, of Siberia and Central Asia." Besides the difficulty of keeping them until they are large enough to flower, they rarely if ever survive after that takes place, and a well-known grower has suggested their being biennial, an opinion we are inclined to agree with. A large plant of *P. Stuartii* we remember having seen in flower on the old rockery at Kew a few years ago, and which we found had never been seen afterwards. *Stuartii* has flowered at various times, but *purpurea* I have never seen, nor has anyone to whom I have spoken about it. The seed germinates freely, but I have never seen the seedlings live beyond the second year. We grow them in peaty soil in a northern exposure. *P. Stuartii* grows between a foot and 18 inches in height. Leaves all coming from the root, broad, lanceolate, pointed, sharply serrated, and covered on the under surface with a golden yellow meal. The flowers varying from ten to twenty, are produced in an umbel surrounded with narrow bracts, each flower about an inch in diameter, yellow, with an orange centre, and drooping as in *sikkimensis*. It was found by Royle at an elevation of 9000 feet, and flowered in the Edinburgh Horticultural Society's Garden 1847. It flowers July. Var. *purpurea*, Royle, much the same as the above, but with purple flowers and sulphury meal on both sides of the leaves. Syn., *macrophylla*, Don, *Jaeschkiana*, Kern. Other varieties are *macrocarpa*, *Moorcroftiana*, and *lineariloba*.

*P. STURII*, Schott (*minima* × *villosa*, Kern).—Found in Steiermark in 1856, and about which Professor Kerner says it is very probable that the plant found by Zahlbruckner on the Waldhorn Alps, a short distance south of Schladning in Steiermark, and described, 1820, as *P. truncata*, Lehm, and which Lehmann later determined to be *minima* var. *pubescens*, is a cross between *minima* and *villosa*, but without personal knowledge of the locality where Zahlbruckner found the plant, and without having seen the original specimens I cannot settle the question. If the suggestion is proved the name *truncata* must be kept up and

*P. Sturii* put as a synonym. We have not seen the plant growing. *Syn. minima, var. pubescens, Josch.*

*P. SUFFRUTESCENS, A. Gray.*—One of the most charming little shrubby *Primulas* we have yet seen, and with the exception of *P. marginata* is the only one known to us with this curious habit. Fortunately, it is very easily cultivated, as shown by a large piece growing on the rockery at the Tottenham Nurseries, and we believe T. S. Ware to be the introducer of this gem. It is doing well with us in strong loamy soil, with small pieces of sandstone round the neck, and plentifully supplied with water during the season of growth. The whole plant is nearly glabrous, leaves thick, leathery textured, cuneate spatulate, and coarsely, sharply toothed at the apex. Leaves crowded on the top of the stem, the old ones being rather persistent. Stem upright or sometimes creeping. Scape about 6 inches in height, carrying three to ten flowers, deep maroon purple, with a large yellowish eye, the tube longer than the calyx, and about the same length as the lobes. Exposed rocks of the Sierra Nevada at 9000 to 11,000 feet elevation, Silver Mountains, &c. First discovered by Bridges above the Jeosmite Valley. The thick matted roots are said to fill the crevices of the rocks, and are more creeping than in any other species. Flowers April and June.—D.

### BURGHLEY PRODUCTIONS.

**CHOU DE BURGHLEY.**—It says much for anything new when it is criticised in the Press; it shows the interest taken by growers, and leads to a correct estimate of its value. I have before had something to say in favour of Chou de Burghley, but it was objected by "A Working Man" through there not having been any weather to test its hardness. Another year's experience of it only confirms the views I had formed. It is an excellent winter vegetable, taking the place of Cabbage from October to April inclusive, and superior in flavour at that season, having a taste of Cauliflower along with Cabbage, and in spring the Cauliflower flavour is very decided in the Broccoli-like hearts. Sown in March or early April it forms large Cabbage-like heads by October, and these may be calculated on to be fit for the knife and pot any day from then to spring, as wet weather does not affect the heads to anything like the same extent as Cabbage and Savoy, for while the Cabbage and Savoys are split and torn into shreds, Chou de Burghley is unaffected by fog or rain. Frost (and "A Working Man" will note this) has very little effect upon it, and there has surely been enough frost and cold to test the hardness of anything. After standing the winter in an open situation I had a large batch that were not any worse in March, and then came in most acceptably. They were from a sowing made early in May, and afforded a capital succession to those sown earlier. I found by planting in firm soil the plants were much dwarfer and formed closer hearts.

**CHOU DE GILBERT.**—I had this for the first time. It may be described as a Cabbage-Brussels Sprout, the Cabbage-buttons clothing the stem as in Brussels Sprouts. It grew strongly, attained to a height of 3 feet, and were studded with little Cabbage-heads from the bottom to the top of the stem. The heads or buttons are exactly similar to Brussels Sprouts, only smooth and shining, not crumpled, and more prolific. The quality when cooked is excellent, having the sweetness of Cabbage, most delicate and delicious. It seems quite as hardy as Brussels Sprouts, not being in any respect injured by the frost of the past winter. It was considered quite a delicacy at table, and I consider it one of the best vegetables introduced of recent years, even by Gilbert.

**UNIVERSAL SAVOY.**—I have grown this two seasons. It is a decided improvement upon the Ulm and Vienna varieties, and quite distinct, partaking more of the character of the Dwarf Green Curled than those varieties, and is much hardier. It is very dwarf and turns in quickly, being next to all heart, there being few useless outside leaves, and the quality excellent. Asking how it was liked at table, I was answered, "Capital, delicious, delicately flavoured." It is one of those things that can be grown by everybody, and it does not require much space. I gave it 18 inches distance, and that was ample. Those requiring small heads may give it less. It stands wet well, and frost does not damage it nearly so much as the yellow-hearted sorts. I have cut it in spring when others had only split or decayed heads, and it keeps a long time fit for use. In order to obtain a late supply a sowing should be made at the end of May or early in June for putting out after early Potatoes.

**PRIMROSE HARBINGER.**—Primroses are the most popular of our hardy flowers; even the Violet is losing ground. I wish the Primrose League would associate the Violet with the Primrose, the "bit of blue" shows off the Primrose so gloriously. Gold and purple go well together. Harbinger Primrose has foliage like the common Primrose, only more shining or less hairy. It is quite hardy, and adorns a hedgebank, copse, shrubbery, and garden quite as well as window, greenhouse, conservatory, and boudoir. It is a plant for the million. Its flowers are large and as fine in form (lacking the fringe) and sweeter than the Chinese *Primulas*, with the difference that the one is suited to everybody and the other only gladdens those with greenhouses. Its flowers are white, primrose-tinted, yellow eye, and sweetly scented. The flowers are borne in trusses—*Polyanthus*-like—and yet without the stiffness of that flower, but diffused openly have a grace exceedingly attractive. Outdoors it flowers with the Primrose, being at its best in the spring, and is fine for spring bedding, imparting a richness to borders through its purity, superior form, and floriferous character. For pots I find it extremely useful as

plants have only to be lifted from the open ground, potted, and stood in a cold frame, from which they can be drafted at intervals to a greenhouse, so as to afford a succession from the New Year to April. Well-grown plants are invaluable for house as well as conservatory decoration, and being hardy they are available where tender-flowering plants are not. It increases rapidly by division after flowering, planted in good soil on a summer-shaded border, but not by overhanging the ground and rendering it as hard and dry as a barn floor. Primroses like moisture and as much sun and light in winter as possible.—G. ABBEY.

**THE PRIMULA CONFERENCE.**—This Conference will be held on Wednesday, the 21st inst., in the Royal Albert Hall. The chair will be taken at noon punctually by John T. D. Llewellyn, Esq., Penllergare, Swansea. The following papers will be read and discussion invited thereon. The first in order is that by Mr. Shirley Hibberd, "On the origin and history of the florists' *Auricula*;" second, "In what direction should efforts be made with the view of improving the florists' flowers belonging to the genus *Primula*?" Mr. Barlow has been unable to prepare a paper on this subject, but the Rev. F. D. Horner has kindly consented to take his place. Mr. J. G. Baker, of the Royal Herbarium, Kew, will next discourse "On the nomenclature of alpine *Primulas*;" while to Dr. Masters has been committed the important subject of "Root structure and mode of growth, as affording indications of the probable best culture."

— AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday, Maxwell T. Masters, Esq., M.D., in the chair, the following candidates were unanimously elected Fellows—namely, Alexander Finn, John Goddard, Leonard G. Sutton, and John Wright. M. Treub was elected a Foreign Member.

— PRESENTATION TO MR. W. J. IRELAND.—On Thursday last a few friends and fellow servants of Mr. W. J. Ireland met him in Kells to present him with a handsome gold watch as a small token of their esteem and regard on his leaving Headfort Gardens to take charge of those of Lord St. Oswald, Nostell Priory, Wakefield, Yorks. Mr. Ireland, in replying, thanked them for the honour done to him, and said he would always look back with feelings of pleasure on the time spent among them.

— WE understand that the first-prize silver medal, offered by the ENGLISH ARBORICULTURAL SOCIETY for an essay on the "LARCH DISEASE," has been awarded by the Judges to Mr. Clark, of Clark Brothers and Co., nurserymen, Carlisle, the second-prize bronze medal being awarded to Mr. Coupar, Ashford, County Galway, Ireland. The publication of these essays will be looked forward to with interest, as whole plantations of Larch are supposed to have been destroyed by this cause all over Great Britain and Ireland.

— ROYAL AQUARIUM, WESTMINSTER.—We are requested to state that, owing to the enlargement of, and to the extension of the time for holding the exhibition by the Kennel Clubs, the Rose Show announced for June 25th and 26th is entirely withdrawn; and the Strawberry Fête and Show, announced for July 2nd and 3rd, is from the same reason postponed until July 9th and 10th.

— MR. STEPHEN CASTLE, West Lynn Vineyard, King's Lynn Norfolk, states that he "Caught the first QUEEN WASP on Friday, the 9th, and another on the 12th. What this means I hardly know after the severe late winter."

— WE are informed that, owing to continued ill-health, Mr. JOHN SMITH has felt it incumbent upon him to resign his post as Curator of the Royal Gardens, Kew, an appointment he has held for twenty-two years. A brief notice of Mr. Smith's career will be found on another page.

— THE statement made on page 160 of the "Gardener's Year Book" for 1886, to the effect that the horizontal tubular boiler there figured and said to be advertised by the Thames Bank Iron Company as the "ROCHFORD" BOILER, is an error. The boiler under that name, we

are informed, is made, advertised, and supplied only by Messrs. C. P. Kinnell & Co., 31, Bankside, London, who are the sole proprietors.

— MR. J. MALLENDER, Hodsock Priory Gardens, Worksop, Notts, writes—"The minimum thermometer in my WEATHER SUMMARY in last week's Journal is made to read 5.7°; it ought to read -5.7, which makes 10° difference, the actual lowest readings of the minimum on the grass were on the 5th 0.1, on the 7th -5.7°, on the 10th -1.5°; so, had it not been for the snow, we must have suffered very much."

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 21st inst., at 7 P.M., the following papers will be read:—"The Climate of Killarney," by the Ven. Archdeacon Wynne, M.A., F.R.Met.Soc. "Note on the Probability of Weather Sequence," by Lieut.-Col. C. K. Brooke, F.R.Met.Soc. "Account of the Cyclone of June 3rd, 1885, in the Arabian Sea," by Capt. Maurice T. Mess. "Results of Solar Radiation Observations in the Neighbourhood of Birmingham, 1875-1884," by Rupert T. Smith, F.R.Met.Soc., M.Inst.C.E. "Results of Meteorological Observations made at Kwala Lumpur, Malay States, 1884," by A. W. Sinclair, L.R.C.P.

— MR. ROBT. OWEN, Maidenhead, sends us some blooms of CINERARIAS of good size, bright and varied in colours, evidently a good strain. Mr. Owen states that the strain is the result of several years' careful selection, the chief objects having been to obtain good substance with varied tints.

— ROYAL HORTICULTURAL SOCIETY.—Amongst the privileges of the Fellows of this Society are the following:—"Each Forty Guinea Life and Four Guinea Annual Fellow is entitled to purchase two tickets, and each Twenty Guinea Life and Two Guinea Annual Fellow one ticket of admission to the Exhibition Buildings through which the Royal Procession will pass on the occasion of the opening of the Colonial and Indian Exhibition by Her Majesty the Queen on May 4th, at the price of 10s. per ticket, instead of £1, the price charged to the public. Application for these, accompanied by a remittance, should be made as soon as possible to the Secretary, Royal Horticultural Society, South Kensington, S.W., and no tickets can be issued after 3 P.M. on the day preceding the opening day. Only bona fide Fellows of the Society are entitled to purchase these tickets, and not their nominees. They will not admit to the Royal Albert Hall, where the opening ceremony will take place. Fellows are informed that each ordinary Fellow's card ticket (green) should be signed by that person in whose name it has been issued, and that, in addition to personal admission to the gardens and Exhibition at South Kensington, such ticket will admit the owner to the Royal Horticultural Society's Provincial Show at Liverpool, from June 29th to July 5th, accompanied by one friend. The paper orders (pink) giving admission for 6d. on 1s. days require the signature of the Fellow of the Society to whom they have been issued." The Orchid Conference Report, published by the Society, may now be had, free of charge, on application to the Secretary.

— MR. J. LESLIE, the Lodge, Pilcullen House, Perth, sends us blooms of CHRYSANTHEMUM FAIR MAID OF GUERNSEY, from plants that have been flowering since December, and asks if it is usual for this variety to bloom so long. It is certainly not usual for such fresh blooms to be sent to us on the 12th of April, and the plants that produced them must have had the best of attention.

— THE NATIONAL CHRYSANTHEMUM SOCIETY'S ANNUAL REPORT AND SCHEDULE OF PRIZES FOR 1886 is now to hand, from which it appears that three exhibitions are provided—one of early Chrysanthemums, Dahlias, and Gladioli, September 9th and 10th; the Annual Chrysanthemum, Fruit, and Vegetable Show, November 10th and 11th, and a Mid-winter Show of Chrysanthemums, Cyclamens, and Primulas, January 12th and 13th, 1887. All these will be held at the Royal Aquarium, Westminster, and the prizes are very liberal in the majority of classes. It is satisfactory to see the Society making such good progress, the number of members having greatly increased, and twenty other societies are now affiliated to it. Schedules can be had from the Hon. Sec., Mr. William Holmes, Frampton Park Nursery, Hackney.

— THE COMMITTEE of the PRESTON AND FULWOOD HORTICULTURAL SOCIETY held their fortnightly meeting on April 10th, when Mr. W. Swan of The Gardens, Howick House, Preston, read a most interesting paper, his subject being "ORCHID CULTURE." The reading was full of valuable and practical information to those present, who

numbered over fifty. The Committee very cordially invite all gardeners, under gardeners included, and there are on all occasions crowded meetings. Mr. Swan alluded to the importance of suitable structures for Orchids, giving many valuable hints upon the best means of heating, ventilating, and shading. He strongly condemned the use of white spar in Orchid houses, and in every case it should be discarded for common cinders or ordinary coke, the latter being preferable, as the spar becomes partially green and unsightly in a very few weeks, and thereby requiring to be washed frequently. Plants never appear so green when staged upon it as they do when placed upon coke or cinders. These latter also absorb a great amount of water. Mr. Swan, being a most successful grower of Orchids for many years past, rendered the subject all the more interesting. A few questions were asked by several members, which were answered by Mr. Swan, after which a little discussion followed by Messrs. Atherton, Roberts, Clarke, and others. A hearty vote of thanks was accorded for his excellent paper, which brought a most pleasant evening's proceedings to a close.

— AT a recent meeting of the LINNEAN SOCIETY Mr. J. G. Baker exhibited *Scelopendrium Devalyi*, a new species of Fern discovered by the Abbé Devalyi in the province of Yunnan. A paper was read, botanical observations made in a journey to the Naga Hills (between Assam and Manipure), by Mr. C. B. Clarke. Writing from Kohima, a station 4750 feet altitude, he says the country above 5000 feet is nearly all jungle, and that the predominant plant groups, such as the Commelinaceæ, Rubi, Senecio, and Ferns, besides others, are nearly all identical with those growing in Sikkim, while, on the contrary, many Khasi plants are conspicuously absent. Various kinds of Oaks form forests around Kohima, and the Alder is abundant, the latter occasionally having an enormous trunk. The Nagas pollard the Alder at 6 feet from the ground, and cut the innumerable sprouts for firewood. Two rare species of Diospyros were observed. The flora is altogether rich and interesting, though there are few new species. Mr. Clarke gives an account of his ascent of Jakpho, a mountain peak 9980 feet high, and about 10 miles distant from Kohima. *Lomaria glauca*, a rare Fern in Khasia, is here plentiful, *Rhododendrons* are plentiful at 8500, and the ridge at the top is clothed with dwarf Bamboo. The levels 5000 to 7000 feet on Jakpho are mostly forests of shrubby *Strobilanthes* 6 to 12 feet high, just as in Sikkim. There are several Laurels, and *Ilex Aquifolium* exists as a tree 30 to 40 feet high. The *Convolvulaceæ* are prominent up to 5000 feet.

— AT the same meeting the Secretary read a communication on the VEGETATION OF THE ARCTIC REGIONS by M. Buysman. The author remarks that the flora of Greenland is decidedly Scandinavian in character. Almost all the plants are also found in Lapland, but, notwithstanding the proximity of America, few belong to that continent, while Asiatic Arctic types are rare. Some 378 species of phanerogams and cryptogams compose the Greenland flora. Of these over 200 are found on the eastern coast, only seven of them being absent on the western shore, while 170 species are recorded from the west, these being absent on the east. Nova Zemlya and the Island of Waigatz together possess 290 species, and Spitzbergen 117 species. The author enters into particulars regarding the special plants peculiar to the seaboard, and such are cultivated by the inhabitants both in the open air and under cover. He remarks that the long and continuous summer sunlight, and at times intense heat, have much influence on the vegetation, and counterbalance the dark severe winter season.

— COMMENTING upon the forthcoming INDIAN AND COLONIAL EXHIBITION AT SOUTH KENSINGTON, *Nature* remarks that "The collection of woods from the Andaman and Nicobar Islands, shown at the Forestry Exhibition at Edinburgh, has been greatly enlarged, especially by specimens of timber of extraordinary size from the Andamans, and will be shown in the Indian section. One of these, the *Diospyros Kurzii*, a marble wood, resembles a combination of oak and ebony. There will be two timber trophies from the Indian Forest Department; one will be a triple arch 46 feet broad by 15 feet high, containing over 300 kinds of wood, while the second will be formed wholly of bamboo, of which thirty species will be shown. The most original arrangement of woods, however, is that adopted in the Victorian Court. Each specimen is in the shape of an octavo volume, on the back being printed, as a title and place of publication, the scientific name of the wood and the locality when it came. The whole collection is enclosed in a handsome book-case, and so resembles a small library. Prof. McCoy and Baron von Müller have prepared a large natural history collection, and one of rare plants

from Victoria in albums. The Melbourne Botanical Gardens send a collection of fibres and carpological specimens. In a natural history case in the Canadian section, prepared by Col. Stockwell, will be a general representation of the fauna and flora of Anticosti. It may be hoped that one result of this Exhibition, and of the meeting of colonists from all quarters of the globe simultaneously in London, will be the establishment of a permanent colonial museum in London. The Exhibition will supply abundant materials with which to make a beginning."

### ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE spring Exhibition of this Society was held on the 7th and 8th insts. in the Waverley Market, Edinburgh. The number of the exhibits seemed smaller than in former years, and in some cases the quality was not quite so good. This was notably so in the case of Azaleas and stove and greenhouse plants, while the tables of plants arranged for effect were fewer in number. Hardy spring-flowering plants were generally poor. On the other hand, we must note the improved quality of the Orchids, while in the case of the Dutch bulbs there was certainly no falling off either in numbers or quality. Cut flowers were also well represented, and of the commoner plants, such as Arums, Primulas, Cinerarias, &c., quite a large show was made. On the second day the Society repeated an experiment which was initiated in autumn last by allowing a large number of children (1500 to 1700) from schools and institutions to visit the Exhibition. They enjoyed themselves to the utmost, and finally, through the generosity of an Edinburgh citizen, each left the building with a present. Managers of shows in populous centres should note that not the slightest damage was done.

The best prizes were offered for the tables of plants. In the nurserymen's section Messrs. R. B. Laird & Son were the sole exhibitors, and had a very neat arrangement, rendered bright with Azaleas and other plants in season. In the gardeners' section Mr. Grossart, gardener to J. Buchanan, Esq., Oswald Road, took first. The arrangement was the common one of a groundwork of Ferns with dot plants. The best of the latter were Orchids and several good Hyacinths. There was a lack of finish which might have been avoided. The second prize went to Mr. Smith, Restalrig. For a table of hardy spring-flowering plants (open) Mr. Munro Robertson, Portobello, was first, and Mr. J. Sinclair, Preston Kirk, second. Much inferior produce was exhibited on both tables, possibly unavoidable on account of the previous bad weather. Of the many prizes offered for hardy plants, Primroses, Auriculas, and so on, none brought forward any plants of extra merit. The first and second prize collections of six Alpines, from Mr. Kerr, Sunlaws, Kelso, may be excepted. Mr. John Patterson, gardener to Jas. Syme, Esq., Millbank, showed four good Azaleas, gaining the first prize; Messrs. Ireland and Thomson, and R. B. Laird & Sons, being first and second respectively in the nurserymen's section for the same plants. In Mr. Patterson's first prize stand of six stove or greenhouse plants, were good specimens of *Acacia armata*, *Erica Bothwelliana alba*, and *Tetratheca ericoides*. In Mr. Grossart's second prize collection was a magnificent specimen of *Cymbidium Lowianum*, also of *C. eburneum* and *Dendrobium fimbriatum oculatum*. Mr. J. Patterson was again first for four Cape Heaths, the plant being small in size, but well bloomed. Orchids, as has already been stated, were fine. Mr. Grossart was the only exhibitor for six plants, having a very good *Cymbidium Lowianum*, *Cœlogyne cristata*, *Vanda suavis*, and *Ada aurantiaca*. In the class for three plants, Mr. Curror, gardener to G. Douglas, Esq., Eskbank, was first with a very fine *Vanda suavis*, good *Cattleya Trianae* with seventeen blooms, and *Dendrobium nobile*. Mr. Grossart with *Dendrobium densiflorum* was first for one plant. A fine example of *Dendrobium Findleyanum* was noticeable in one collection. Two flowering plants of *Cattleya Lawrenceana* were staged, the one from Mr. Grossart, the other from Messrs. Thomson & Sons, Clovenfords. The latter firm also exhibited the new hybrid *Dendrobium Leechianum*. To all three plants first-class certificates were awarded.

Ferns were not largely shown, and mostly the plants were small. The best four exotic Ferns came from Mr. Hunter, gardener to T. Craufurd, Esq., Lauriston Castle. Mr. Patterson, Millbank, showed three good *Gleichenias*. In the classes for Dutch bulbs, Mr. Watson, Newcastle-on-Tyne, in the nurserymen's section, took first prizes for twenty-four Hyacinths, six pots of Tulips, eight pots of Narcissus, and extra prize was also awarded him for six pots of well-flowered Lily of the Valley. Mr. McKenzie, 63, Vincent Street, Glasgow, was second for twenty-four Hyacinths, Messrs. R. B. Laird & Sons, Edinburgh, being second in the Tulip class. In the gardeners' section, Mr. Kerr, Sunlaws, Kelso, was first for twelve Hyacinths, spike good but rather drawn; Mr. Pearson, gardener to Lady Lucy Dundas, Beechwood, a very good second. Mr. R. Laurie, gardener to G. D. Mackay, Esq., Crammond, had first for eight varieties, and Mr. Laurie, gardener to Professor Calderwood, Murchiston, first for six. For eight pots Tulips, Mr. Grossart was a good first, and Mr. Grey, gardener to Wm. Christie, Esq., Craigend, first for six pots. Mr. Grossart six pots *Polyanthus Narcissus* was again first, also for nine *Narcissus*. A large number of *Deutzias* was shown, as also *Coleuses*, table plants, foliage plants, *Cyclamens*, *Primulas*, *Arums*, *Lilies*, and *Lily of the Valley*, most of these being good and above the average. We must not omit to mention the enormous specimens of *Rhododendrons* with which Messrs. Laird took the honours in the nurserymen's classes. Smaller plants of these were also well shown.

The display of fruit was not large. Only two Pine Apples were staged, Mr. McIntyre, gardener to Sir C. Tennant, Bart., M.P., The Glen, Peebles, being first with a good Smooth Cayenne. Five exhibitors showed Black Grapes, Mr. McLennan, gardener to Lady Emma McNeill, Liberton, being first with a brace of Lady Downe's; and with the same sort, Mr. McKelvie, Broxmouth Park, Dunbar, second. Mr. Dow, gardener to Sir David Baird, Bart., Dunbar, had six pots of Strawberries. For a dish of the same fruit Mr. McIndoe, Hutton Hall, Guisboro', was first with very fine Keens' Seedling, Mr. Dow second with *Vicomtesse Hericart de Thury*. A goodly display of Apples was provided, Mr. Potter, Seacliffe, North Berwick, being first with collections of both, his fruits being fresh and well kept.

Of cut flowers, the Roses were the main attraction, Mr. R. Green, Falcon Hall, being first for twenty-four blooms, and Mr. Gordon, Niddrie, second. For twelve blooms, Mr. Bowman, Lasswade, was first, Mr. Walker being first with twelve *Gloire de Dijon*, and Mr. Pearson, Beechwood, with *Maréchal Niel*. For twelve trusses of stove or greenhouse plants, Mr. McLeod, gardener to C. Smith, Esq., Brentham Park, Stirling, was awarded first, his flowers being almost all Orchids. Mr. McIndoe second, with a much better-looking collection. Camellias and *Rhododendrons* were also shown as cut flowers, and several good bouquets were set up both by gardeners and nurserymen.

Of vegetables there was a fair display. Two baskets were forwarded, Mr. Potter, Seacliffe, having the best Potatoes, Peas, French Beans, Brussels Sprouts, and Leeks were the best examples in Mr. Potter's collection. Extra fine Mushrooms were shown by Mr. Smith, Restalrig, and Mr. Gordon, Niddrie. Salads and various other vegetables were also well shown. Handsome tables of plants were arranged by Messrs. Methven & Sons, by Messrs. Dickson & Co., by Messrs. Ireland & Thomson, Mr. Sinclair, Prestonkirk, and Messrs. Seth, florists.

In addition to the first-class certificates already noted, Messrs. Canneff and Sons, Swanley, Kent, were awarded one for blooms of *Pride of Penhurst* Carnation, a very beautiful pure yellow variety of medium size. During the two days the Exhibition was open it was largely patronised, the railway companies running excursion trains from various districts, thus bringing a larger constituency under the influence of the Society.

### MILNHURST, ECCLESHALL, SHEFFIELD.

THIS is one of the finest amongst the many handsome and costly suburban residences around Sheffield, and is of very recent date, having been completed at a great cost by Major Blake, J.P. (a partner in the well-known firm of Stephenson & Blake, type founders), as a residence for himself and family three or four years since. The mansion, which is built of dressed ashlar stone and the style of which is early English, is about two miles from the town of Sheffield, on high lands, commanding magnificent views of the Peak district (Derbyshire), to which it is contiguous. The grounds in all occupy an area of about ten acres within the walls. The pleasure grounds and gardens are very complete and fine in all their details. The major has for years been locally well known as a lover and a liberal patron of horticulture; I find also he is a reader of and subscriber to our Journal. The grounds, which were naturally of a pleasing, undulating character, have been well arranged and laid out so as to make the most of the natural formations. The lawns are somewhat extensive, and fall by gentle slopes from the front of the mansion towards a sheet of ornamental water, which is very effective seen from the terrace.

There are some good kitchen gardens and a fine fruit orchard at different levels and sloping towards the south-west, but the most imposing feature of the grounds is the splendid range of plant-stoves, fruit houses, &c., recently erected by Messrs. Foster & Pearson, Chilwell, Notts, which for excellency of construction and workmanship, convenience of arrangements, suitability for the purposes they are intended to serve, and general completeness, cannot be surpassed, if indeed equalled, in this district. They are so arranged as to be all connected with each other, and a tour may be made of the whole without once stepping into the open air. They consist of three span-roofed stoves, the central one being 40 feet by 20 feet; the other two being each 30 feet by 13 feet; also a lean-to vinery about 40 feet by 20 feet. These four houses running parallel with each other, having an intermediate space of about 20 feet between each house, and the whole being connected at their north-easterly ends by a lean-to range about 100 feet in length by 12 feet wide. This range is divided by partitions into several houses, one of which is devoted to Peaches and the others to greenhouse flowering plants and Ferns. At the back are the potting shed, fruit room, Mushroom house, stokeries, &c., all most conveniently arranged and well fitted throughout. The potting shed is a model of what such structures should be, being large, lofty, and very light, the roof a glazed one throughout, well fitted with all necessary cupboards, shelves, and racks, the motto appearing to be, "A place for everything and everything in its place;" also fitted at one end with lavatory and towels for the use of the young men, and well warmed by a service of hot-water pipes.

In the Mushroom house is an admirable arrangement of beds on each side a central pathway, supported upon cast metal columns, which columns are grooved for holding slate slabs, such slabs being made to slide freely in and out these grooves, and being therefore easily removable when required, making the work of emptying and refilling the beds much more convenient thereby. In the lean-to greenhouses are a good collection of Camellias and Azaleas in vigorous health. The back walls of each house are also well covered with greenhouse climbers, especially notable amongst which is a large and very vigorous *Lapageria rosea*. This is planted out in an arrow border at the foot of the wall, and was removed from a similar position at Major Blake's previous residence about a year and a half ago. It appears to have suffered little by the removal. The Peach trees planted out in the Peach house were removed from the same place to their present position in the autumn of 1884, bearing good crops of fruit last summer, and giving promise of doing the same again this season.

In the stoves is a good collection of Orchids, especially notable amongst which for vigour, floriferousness, and high colouring are the *Dendrobiums*. The latter feature I have never before noticed so prominent in all varieties alike in any collection, and I attribute it to the extreme lightness of the houses in which they are grown. A large batch of *D. Bensoniæ* is here noticeable for the vigorous growths they have made. *Phaius Wallichii* and *grandiflora* are here flowering superbly. One plant of the latter has five spikes each 4 feet and averaging twenty-two flowers on each. In

another house are exceedingly fine varieties of *Odontoglossum Alexandræ* and *gloriosum*, also of *Masdevallia ignea* and *Oncidium macranthum*.

The Vines which were planted in May, 1884, have made wonderfully strong rods in addition to maturing last summer three or four bunches each of very fine fruit. One, a Foster's Seedling, carried ten large bunches last year. Throughout all the houses excellent management and skilful culture are apparent, and show the love of horticulture and judicious liberality of the proprietor, with the skill and industry of his gardener, Mr. Herriot.—W. K. W.

#### ORCHIDS AND SPRING FLOWERS AT UPPER HOLLOWAY.

MR. B. S. WILLIAMS has provided an extensive display of bulbs and miscellaneous forced plants in the large conservatory at the Victoria and Paradise Nurseries this season, while in the numerous other houses the Orchids are contributing greatly to the attractions. Of the bulbs the Hyacinths are particularly fine, the spikes and bells large, the colours

its place amongst the most useful and popular species; it is very distinct, free flowering, the colour is extremely good, and a sufficient number has been imported to render the price moderate, though the better varieties will command good prices. The petals are  $1\frac{1}{4}$  to  $1\frac{1}{2}$  inch in diameter, the sepals are narrower but of similar colour—namely, a soft purplish crimson hue, the lip being somewhat tubular, of an intensely rich crimson tint, with a white throat. Two to four flowers are borne in a spike, and one plant in Mr. B. S. Williams' Cattleya house is showing twenty spikes, justifying the comparison between this and *C. Skinneri* as regards floriferousness. The illustration (fig. 52) was prepared from one of the Holloway plants, and gives a good representation of the form of flowers and habit.

It would be unnecessary to enumerate all the Orchids in flower at these nurseries now, but a few may be mentioned. *Lycaste Skinneri* is still attractive, the variety *amabilis* with pale pink flowers being especially good, the Chatsworth variety of *Coelogyne cristata*, the orange-coloured *Lælia harpophylla*, the useful *Sophranitis grandiflora*, *Phalenopsis*

Fig. 52.—CATTLEYA LAWRENCIANA.

clear and bright, and all the best varieties are represented. Tulips are exceedingly bright, and Lilies of the Valley are wonderfully fine; very rarely indeed are such good examples seen. With these are associated Azaleas, Deutzias, and other plants, a suitable proportion of foliage being furnished by the Tree Ferns and Palms, of which such handsome specimens are included in this spacious house.

In the Orchid houses visitors find abundance to admire, all looking remarkably healthy, and Cattleyas and Lælias are showing hundreds of sheaths, in addition to the numerous spikes of flowers now expanded. Cattleyas Warneri and Trianae are beautiful, the latter in several varieties. *C. Mossiæ* is also showing well, and of this with *C. Mendeli* there are about 500 sheaths, giving promise of a grand display a little later. The magnificent Lælias of the *L. purpurata* type, of which there is so large a stock and so many fine varieties, are looking well, and will furnish many hundred flowers in a few weeks. Very notable amongst many others is the new *Cattleya Lawrenciana* that has been certificated this year at South Kensington, Regent's Park, and the Crystal Palace, a trio of honours which it well deserves. Some of the earliest flowers produced were rather disappointing, and unfavourable opinions were expressed concerning it; fortunately these doubts have been removed as the plants became stronger and other flowers have been produced. This *Cattleya* will probably take

*Stuartiana*, *P. grandiflora*, and *Schilleriana* are also flowering freely. The Vandas are in capital condition. There are several beautiful *Cypripediums* in flower, and in the cool house there is a choice collection of *Odontoglossum Alexandræ* and *O. Pescatorei*, varieties comprising some of the best in cultivation. There is also a large stock of *Masdevallias* of the principal species.

Another great specialty at Upper Holloway are *Imantophyllums* and *Amaryllises*, which have houses devoted to them, where they afford a brilliant display. The *Imantophyllums* are extremely showy, and they well deserve more attention in gardens, especially now so many improved varieties have been obtained. They are easily grown, flower abundantly, and their bold dark green foliage renders them ornamental even when not in flower. The *Amaryllises* have been special objects of Mr. Williams' care for many years, and a valuable strain has been gradually formed, with flowers remarkable for their neatness of form and brilliant colours, in which respects they are unsurpassed. The house devoted to these plants is very gay now with the innumerable spikes, and varieties present a wide range of scarlet and crimson tints. In other houses the *Rhododendrons*, *Camellias*, *Ericas*, and hardwooded plants are yielding their flowers freely, while the stoves occupied with miscellaneous foliage plants include much that is interesting and beautiful.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 13TH.

ORCHIDS and Daffodils were again the most important and beautiful of the exhibits at South Kensington; the former from several amateurs, but especially from Sir Trevor Lawrence, Bart., M.P., were admirable, the Daffodils also being largely represented by collections from the nurserymen who make a speciality of those and other hardy plants. One of the greatest attractions was the group of New Zealand Forget-me-nots from E. G. Loder, Esq., the plants being exceedingly healthy and bearing numbers of their pretty blue-tinted flowers. The Berkhamstead Rhododendrons, with miscellaneous contributions from various sources, occupied the whole of the remaining table space on both sides of the conservatory, and formed the most imposing display held by the Society this year.

**FRUIT COMMITTEE.**—Present: T. Francis Rivers, Esq., in the chair, and Messrs. H. J. Veitch, Wm. Denning, John Burnett, F. Rutland, Wm. Paul, John E. Lane, James Smith, Joseph Ellam, John Woodbridge, William Warren, T. J. Saltmarsh, G. Goldsmith, Chas. Silverlock, T. B. Haywood, and R. D. Blackmore. A silver medal was awarded to Mr. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, for an excellent collection of Apples, comprising fifty dishes, nearly all distinct varieties, and six dishes of Pears, the fruit being firm and extremely well kept. The best varieties of Apples were Dumelow's Seedling, Lord Burghley, Winter Colmar, Ribston Pippin, Stone Apple, Glove Pippin, Maiden Millet, and Brabant Bellefleur; the Pears being Catillac, Uvedale's St. Germain, Duchesse Tardive, and Bezi Mai. A letter of thanks was accorded to Mr. Stephen Castle, West Lynn Vineyard, Norfolk, for several good bunches of Gros Colman Grape, the berries large, plump, and bearing a fairly good bloom. A dish of unnamed Apples from H. A. Brassey, Esq., Preston Hall, Aylesford, Kent, was passed.

**FLORAL COMMITTEE.**—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. R. Dean, John Denning, H. M. Pollett, James O'Brien, W. B. Kellock, R. Hill, G. Paul, H. Cannell, J. Douglas, W. Bealby, Amos Perry, B. S. Williams, H. Herbst, W. Wilks, James Hudson, G. Duffield, Harry Turner, H. F. Lendy, H. Ballantine, William Holmes, and Shirley Hibberd.

Some handsome specimen Orchids were contributed by several growers, but the group from Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, was a most important portion of the Show, including several remarkably well-grown plants, and the silver-gilt Banksian medal awarded them was a worthy recognition of their merits. Very conspicuous in the group was a magnificent example of *Oncidium Marshallianum*, with spreading panicles bearing scores of large flowers, the lip broad bright yellow, the sepals and petals smaller, and spotted with reddish brown. *Odontoglossum vexillarium roseum* is a beautiful variety, the flowers deeply coloured with rose, large and freely produced, the plant shown having four spikes of six flowers each. *Cattleya Lawrenciana* was capitally represented by a plant bearing fifteen flowers. *Cypripedium caudatum* had twenty-two of its peculiar flowers, with long ribbon-like petals. Of *Cattleya Mossiae* there was a fine variety, the sepals and petals bluish tinted, the lips white and gold streaked, pale crimson, very delicate and beautiful. *Dendrobium Harveyanum* and *Brymerianum* were also shown, both golden coloured, the former with the petals deeply fringed, and the latter with the lip similarly but still more deeply cut. *Masdevallia racemosa* Crossi is a very distinct form, bright scarlet, but the flowers curiously contracted. *Maxillaria Turneri* had some hundreds of its small flowers; the rosy crimson *Trichopilia lepida* was attractive; *Cattleya Mendeli*, *Dendrobium crystallinum*, *D. lituiflorum*, and the white *Saccolabium curvifolium album* were also well represented. A series of grand varieties of *Anthurium Schertzerianum*, remarkably well grown, formed a part of the Burford Lodge group. They were as follows: Wardi, thirteen spathes,  $4\frac{1}{2}$  inches wide by 5 inches long; Devansayanum, spotted with scarlet on a white ground, certificated; Rothschildianum, similar to the last mentioned but broader; Hendersoni, Cypher's variety, ten spathes, each 6 inches long by 5 inches wide; Palmeri, having the longest spathes, 8 inches by  $3\frac{1}{2}$  inches broad; Pygmaeum, narrow tapering spathes, and a number of Cypher's seedlings, the spathes of various sizes and shapes. All were exceptionally bright in colour.

An interesting hybrid, *Phalaenopsis intermedia*, was shown by Messrs. J. Veitch & Sons, Chelsea, which has been previously referred to when the first flower expanded, this being the second. It was raised from seed in 1882, obtained by crossing *P. amabilis* with *P. rosea*, which was done to prove if *P. intermedia* was really the natural hybrid it was supposed to be. The flowers produced confirm this view, for they have the true character of *P. intermedia*, the sepals and petals are white, the petals tinged with crimson at the base, the centre and side lobes of the lips are purplish crimson, with a few dots and a yellowish crest at the base, the flowers being about 2 inches across, and the foliage the same as that of a well-grown plant of *P. intermedia*. H. J. Buchan, Esq., Wilton House, Salisbury, exhibited a plant of an *Odontoglossum* which had been received under the name of *liliflorum*, but which was thought to be *ramosissimum roseum*, the flowers 2 inches across, with narrow pink undulated sepals and petals, and a tapering lip with a white crest. They are borne on a panicle at the end of a peduncle 4 feet or more in length, the stiff leaves growing to the length of 2 feet. Mr. Buchan also had flowers of some handsome varieties of *Odontoglossum* Halli and its variety *leucoglossum*, *luteopurpureum*, *Alexandrae*, finely tinted with pale crimson at the base of the petals, *Andersonianum* and *Rossi*, all notable for rich colouring and good size of flower. C. L. N. Ingram, Esq., Elstead House, Godalming (gardener, Mr. J. W. Bond) showed several Orchids; *Odontoglossum Elsteadianum*, having narrow yellow sepals and petals spotted with brown, *Phalaenopsis Sanderiana* superba, and *Odontoglossum Andersonianum* were all notable varieties. W. B. Greenfield, Esq., Beechwood Park, Dunstable (gardener, Mr. Freeman) had a capital spike of *Calanthe vestita igneo-oculata*, the flowers extremely large, white with a brilliant orange centre. A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins) exhibited several plants of *Cattleya citrina* in flower (vote of thanks), *Warszewiczella discolor*, with creamy sepals and purplish violet petals and lip, which some not inaptly compared to a *Gloxinia*, with *Scuticaria Hadweni*, a peculiar plant, with cylindrical or channelled drooping leaves and brown flowers, the lip white veined with pink. A. J. Hollington, Esq., Enfield (gardener, Mr. E. Ayling)

showed a delicately coloured *Odontoglossum Alexandrae* named *roseo-pictum*, white tinged with rose and spotted with brown.

W. Lee, Esq., Leatherhead, contributed a small group of choice Orchids, including some well-flowered *Cattleya speciosissima*, *Epidendrum Stamfordianum* with two panicles of flowers, the distinct and beautiful *Cypripedium Godefroya*, and a variety with finer dots, the charming *Oncidium Phalaenopsis* with small flowers, white, spotted violet crimson at the base of lip, the sepals and petals being barred with a similar but darker tint. A bronze medal was awarded to H. M. Pollett, Esq., for a choice collection of *Odontoglossum*, comprising some of the best varieties of *Andersonianum*, *Ruckerianum* insignis, *Wilckeanum*, *Mulus*, *Pollettianum*, and *Schillerianum*. R. B. Lemon, Esq., Mont Lodge, The Avenue, Beckenham, showed *Oncidium Reichenbachii*, a variety having brown sepals and yellow petals, spotted with brown at the centre. Messrs. J. R. Pearson & Son, Chilwell, exhibited several large-flowered varieties of *Dendrobium Wardianum* and noble, the latter being also deeply coloured.

Messrs. J. Veitch & Sons had a selection of their new *Amaryllises*, one of which, *Princess of Wales*, was certificated. Other good varieties were *Eclatante*, white, striped crimson; *Etoile*, scarlet with a white central star; *Compton*, brilliant scarlet, the white central bars extending half the length of the petals; *Pioneer*, crimson, medium size, but good form and distinct shade of colour; and *Crown Princess of Germany*, white striped scarlet, the flowers rounded and well proportioned. Plants of the interesting dwarf Japanese *Heliconopsis umbellata* were staged by the same firm, the flowers pale pink and drooping, the petals narrow. They rise about 3 inches above the rosette of leaves. The greenish yellow *Fritillaria-like Korolkowia Sewerzowii* was also shown. Mr. B. S. Williams, Upper Holloway, contributed a group of plants, the *Imantophyllum* being very fine, the varieties *aurantiacum* and *Ambroise Verschaffelt* being noteworthy for the massiveness of the umbels, the size of the individual flowers, and the rich orange-scarlet shades of colour. *Houlletia odoratissima* is a peculiar Orchid, with brownish-red sepals, the petals and lip being yellowish, the flowers borne in a drooping spike. *Odontoglossum cuspidatum* has yellow sepals, petals blotched with brown, and a white lip. *Masdevallia Harryana lilacina* is a distinct and delicately tinted variety, very pretty in contrast with the darker coloured varieties. *Araucaria Vervaeckiana*, an elegant variety of the excelsa type, and the strangely marked *Bromeliad Vriesia hieroglyphica*, were also shown by Mr. Williams. Mr. W. Bealby, Roshampou, had a good double white *Azalea indica*, named *Sacountala*, very full and pure. G. F. Wilson, Esq., F.R.S., Weybridge, showed flowers of *Megasea speciosa*, large, and of a bright rosy tint. *Primula denticulata purpurea*, and a lovely *Primrose* named *Alice Wilson*, which was certificated. Messrs. H. Cannell & Sons, Swanley, sent flowers of *Carnation Pride of Penhurst*, bright clear yellow, and the scarlet *A. Alegatiere*, which were greatly admired. Mr. F. Perkins, 51, Regent Street, Leamington, exhibited flowers of the now well-known white decorative *Pelargonium Volonté Nationale album*. Mr. James Gray, horticultural builder, Danvers Street, Chelsea, showed a sample of improved Orchid staging, in which the upper part consisted of wood laths in moveable lengths, to allow shingle or ashes on the stage below to be removed with ease. Slate, oak, or elm slabs form the lower stage, resting upon wrought iron standards, and covered with shingle or small coal to retain moisture. It was neatly but strongly constructed, and is one of the best forms of stages for Orchid houses, either over tanks, at the side, or otherwise.

The groups of Daffodils were very extensive and comprised a large number of varieties, the best of which we have mentioned at different times, and the report of the Narcissus Committee will, no doubt, particularise the leading sorts, especially the novelties. Medals were awarded as follows:—Silver Banksian to Messrs. Barr & Son, Covent Garden, T. S. Ware, Tottenham, and bronze Banksian to Messrs. Collins Bros., and Gabriel, Waterloo Bridge Road, New Plant and Bulb Company, Colchester, and Mr. J. Walker, Whitton. Anemones and miscellaneous flowers were included in several of these collections, Mr. Ware's Single Poppy Anemones being exceedingly bright and varied in colour. A silver medal was also awarded to Messrs. H. Lane & Son, Great Berkhamstead, for a group of Rhododendrons in pots, representing many varieties of good colour.

## CERTIFICATED PLANTS.

*Myosotidium nobile* (E. G. Loder, Esq., Floore, Weedon).—This plant, which is popularly known as the New Zealand Forget-me-not, is a native of the Chatham Islands and a member of the Borage family. It was introduced to Europe by Mr. Watson of St. Albans, and first shown in flower before the Horticultural Society in London, March 1858. It was at first referred to the genus *Cynoglossum*, but was subsequently constituted a new genus under the name given. The leaves are heart-shaped, 8 to 9 inches broad, and as much long, with a stout petiole, bright, shining, and deep parallel veins, like a gigantic *Plantago*. The flowers are produced in a cymose inflorescence, forming a rather dense head; they are about half an inch in diameter, of a bright blue in the centre, shading to white at the margin, and much like the *Myosotis* in form. It is a beautiful plant, and the samples shown were wonderfully strong. The gardener at Floore, Mr. J. Goldsmith, states that they are grown in loam, leaf soil, one-third horse manure, and plenty of sand, being placed in a cold frame, but protected from frost. The plant is usually considered difficult to grow and is rarely seen in flower.

*Odontoglossum Pescatorei*, *Knox's Variety* (B. D. Knox, Caversham, Reading).—A supposed natural hybrid between *O. Pescatorei* and another species, but wonderfully distinct from anything yet obtained, and very valuable. The flowers are  $2\frac{3}{4}$  inches in diameter, the sepals and petals broad and rounded, bright yellow, lighter at the base, with a few bold crimson spots, the lip broad, lighter, and with few spots. A superb form and fine companion for *O. Pescatorei* Veitchi.

*Lycaste Skinneri gloriosa* (W. C. Pickersgill, Esq., Blendon Hall, Bexley).—A splendid plant of this was shown with two dozen flowers. The sepals pale bluish, the petals crimson and the lip white. Very handsome and admirably grown.

*Amaryllis Princess of Wales* (J. Veitch & Sons).—A superbly formed flower, the petals broad and round, flushed with pale crimson, and streaked with white, very delicate.

*Amaryllis Crown Princess of Germany* (J. Veitch & Sons).—A beautifully

formed flower, the petals round and well proportioned. It is one of the best of the striped class, which afford such a pleasing contrast with the scarlet and crimson varieties. The ground colour is pure white striped irregularly with bright scarlet.

*Primrose Alice Wilson* (G. F. Wilson, Esq.).—A seedling from Primrose Scott Wilson, the flowers neat in shape and of good size, but chiefly remarkable for the distinct and rich colour, a violet purple with a gold eye, which is surrounded by a crimson margin. An exceedingly pretty variety.

*Masdevallia racemosa* Crossi (Sir Trevor Lawrence, Bart., M.P.).—A distinct variety, brilliant scarlet in colour, the sepals looking as if shortened or contracted, especially the lower ones.

*Anthurium Schertzerianum Devansayanum* (Sir Trevor Lawrence, Bart., M.P.).—One of the same type as *Rothschildianum*, but the spathe is narrower, about  $4\frac{1}{2}$  inches long, boldly spotted with deep scarlet on a white ground, and the back of the spathe is scarlet instead of being dotted as in the other form named.

*Cypripedium Wallisi* (W. Lee, Esq.).—A species of the caudatum section, with tapering greenish sepals, and long narrow brownish-green petals, 12 to 15 inches long, the lip greenish white, pure white in the throat.

*Odontoglossum Courtauldianum* (S. Courtauld, Esq., Braintree, Essex).—One of the luteo-purpureum type, yellow blotched and barred with brown, the lip having a white spot at the base.

#### SCIENTIFIC COMMITTEE.

A. Grote, Esq., in the chair. Present:—Messrs. Llewelyn, Michael, Pascoe, Boulger, Bennett, W. G. Smith, J. O'Brien, G. F. Wilson, Rev. C. W. Dod, A. H. Smee, G. Murray, H. Ridley, Major Clarke, Prof. Church, Dr. Hogg, and Dr. Masters.

*Rhododendrons*.—Mr. Llewelyn exhibited from the neighbourhood of Swansea various *Rhododendrons*, all grown out of doors except *R. Edgeworthii*. The species and varieties included *R. Shepherdii* (?), *R. ochraceum*, *R. barbatum*, *R. Thomsoni*, *R. ciliatum*. Many of these are as hardy as the common Oak, provided they do not make their growth too early in spring. Most of the trees mentioned by Mr. Llewelyn were introduced many years since from Himalayan seed, and have now attained a height of 25 to 30 feet.

*Sparrows and Crocuses*.—Mr. Boulger gave his experience as to the mischief effected by sparrows. Unlike Mr. McLachlan, he had found that the birds principally attacked the edge of the corolla and not the tube. It was remarked that Crocuses in masses were less liable to injury than when in lines.

*Primroses*.—Mr. Boulger exhibited various forms of hose-in-hose Primrose, in which the calyx was petaloid like the corolla, and a malformation in which the stamens were all united into a tube.

*Fungus Poisoning*.—Mr. W. G. Smith read an account of the injurious effects produced on himself by partaking of *Agaricus dealbatus*. The species is capricious in its action, as it does not always, and under all circumstances, produce the effects described by Mr. Smith, and which consisted in a sensation of heat and excessively profuse perspiration. No other ill effect was produced, and others who ate the fungus at the same time were not affected.

*Weevil on Orchid Bulbs*.—Mr. O'Brien showed pseudo-bulbs of *Cœlogyne cristata*, injured by a beetle which was referred to Mr. Pascoe for identification. A conversation ensued respecting *Isosoma* and other insect pests imported with Orchids, and it was suggested that any suspicious-looking plants should be destroyed, but it was pointed out that the damage was probably done in a young state of the insect, and that destruction of the perfect insect or of the affected bulbs might be of little avail. Mr. Llewelyn alluded to certain longicorn beetles imported with timber from the Baltic, and which were illustrations of life under untoward circumstances, the beetles being found in the timber used in the mines after a long period of use under ground.

*Frost on Leaves*.—Mr. G. Murray stated that the leaves referred to him on a former occasion were injured by frost and not by fungi or insects.

*Odontoglossum ramosissimum*.—Mr. Buchan showed a specimen of this plant determined by Professor Reichenbach to be the var. *roseum*, but as the Professor had not seen either leaves or pseudo-bulbs, which differ materially from those of *ramosissimum*, it was considered that the determination was open to doubt.

*Outdoor Orchids*.—Mr. A. H. Smee showed a plant of *Cattleya Trianae* in bloom. The plant was placed in the open air, exposed to full sunshine from June 24th, when the entire growths were made, and taken in again on September 24th. The flowers were of a richer colour than those formerly produced on the same plant under glass. A plant of *Cypripedium insigne* was also shown, which had been out of doors all through the winter with only the protection of a broken handglass. The plant had been exposed in a similar way for two or three years, and this year had been subjected to 22° frost without injury.

*Phatenopsis intermedia*.—A botanical certificate was awarded to this plant from the great interest attaching to the circumstance that this artificially raised hybrid, whose history is given in the report of the Show, proves to be identical with imported plants suspected (and now proved to be of hybrid origin).

*Miscellaneous Exhibits*.—Owing to the number of subjects brought forward, the following subjects were laid on the table:—A specimen of *O. Alexandræ*, in which alternate flowers were fertilised, and had become of a fawn colour, while the virgin flowers remain of their usual colour. A burr of *Abies Douglasi*, showing a condition of things like the *Clanbrassil Fir*. Peculiar growths of the *Laburnum*, in which the growth of last year was much thicker than that of the year preceding.

#### HEDGES.

HEDGES are sometimes planted to afford shelter, but more frequently as a fence. However carefully they may be planted and cared for in a young state, it must be admitted that without the same care in after years they soon become unsatisfactory and unfit for the purpose for which they were planted. Perhaps this remark may apply with much greater force

to hedges on the farm than to those about the garden. How often do we meet with hedges that have been left to grow untended for years, dying at the bottom for want of light and air, and with large gaps. When it gets into this state the farmer finds it is of no use to keep his live stock together, so he cuts it down to the ground, very likely with the good resolution to keep it better in future, but with the result that he has no fence at all for some years to come. Even about gardens hedges sometimes become unsatisfactory, though from a somewhat different cause. They are generally kept under the shears, and if due care is not taken to keep them within bounds they gradually become too wide and heavy at the top, and so become, to a certain extent, faulty at the bottom.

Hedges surrounding plantations are especially liable to fail. They very often are damaged by the trees being too close to them, and in time overhanging them. They are thus weakened and drawn outwards, so that we very often find them similar in shape to that given at A, fig. 53. When such hedges get very bad the usual remedy is to cut them down. This is, however, not always necessary nor desirable. If the timber is well cleared away from behind them, and they are cut in so that they are narrow at the top, similar to the dotted lines in the section referred to, stopping the upper part of them well back, they will generally fill up at the bottom if kept clean and narrow at the top. The best time to do this, or indeed to reduce a hedge in any way, is when the sap begins to move in spring, say from the middle of March to the middle or end of April according to the season. They then soon break in to growth, and are green again in a short time. The ends of the young shoots should be cut off about midsummer, and by the autumn there will be a fair quantity of young growths upon it.

Hedges are to be met with in a great variety of shapes, some of them

Fig. 53.—Hedges.

not commendable. I am rather partial to those with almost perpendicular sides, such as represented at B. But there is no doubt that to keep a good close bottom good enough to turn sheep, &c., the top must be kept a good deal narrower than the base, similar to C. This is not only an advantage in the formation of a good fence, but it is a saving in the labour of keeping. It is quite a common thing to meet with hedges from 2 to 3 feet across the top, and cutting these, propped upon steps or a plank, is a laborious task which may well be avoided. Too much labour is generally expended on the tops of hedges, and too little at the base, in keeping them clean and well furnished. If you can accomplish the latter good quality, the top, which is really of secondary importance, may safely be relied upon to assert its claim to a fair share of the shears, which it should always have. I have sometimes seen young hedges grow four or five years without cutting, to give them strength, and then have them cut down. Is not this a fallacy? I think it is most foolish. If a hedge is from the first turned in the shape of section C, keeping it quite narrow at the top, a good fence will be the result without any cutting down.—R. INGLIS.

#### HINTS ON ORCHID CULTURE.

(Continued from page 271.)

##### ORCHIDS OUT OF DOORS.

MANY of the Orchids already named in the various lists can, under certain favourable conditions, be placed out of doors during the summer months, and the hardier of the cool Orchids seem benefited by such treatment; while with all it has the advantage of keeping them free from insects, and ripens the growths well. It can, however, only be safely done in gardens that are rather sheltered and moist in warm districts, like the southern counties of England. To expose Orchids in hot, dry, or cold gardens would be ruinous, and amateurs who do not wish to lose a large proportion of their plants had better not try such experiments; though with any kind of shelter, as an ordinary frame, most cool Orchids can be grown during the six warmer months of the year. The principal experiments with Orchids out of doors have been tried in Mr. A. H. Smee's garden, where large numbers have been placed out from June to October with satisfactory results, but this garden has a low moist situation, and is otherwise favourable for the purpose. [See *Journal of Horticulture*, p. 392, November 8th, 1883.] Upon the continent similar experiments have been repeatedly tried; indeed it is quite common there to place all but the most tender Orchids outside in the summer. [See *Journal of Horticulture*, pp. 481 and 550, December, 1883.]

## HARDY ORCHIDS.

The hints which have been previously given refer exclusively to the exotic Orchids, which require to be grown in glass houses in this country, but there is a large group of beautiful species, mostly terrestrial, which can be cultivated out of doors. Amongst them are several found wild in Britain, but none the less worthy of attention on that account, though we owe the showiest to North America, such as the beautiful rose and white *Cypripedium spectabile*, which, when well grown, is superior to many of its tropical brethren. *Orchis foliosa* and *maculata*, with crimson and spotted flowers in dense racemes, are also plants of great attraction, and admirably adapted for culture in pots. We have plenty structurally interesting in the genus *Ophrys*, which comprises the Bee, Spider, and Fly Orchids, and many are also sweetly scented. The situation most suitable to the greater number is at the foot of a rather shady bank or rockery, and then the other species which are found on higher lands, and require a chalky or sandy soil, can be accommodated upon the slope. For some a constantly damp soil of peat, leaf mould, and a little turfy loam is the best, such as *Cypripedium spectabile*, *Epipactis palustris*, *Orchis foliosa*, *O. latifolia*, *O. maculata*, and *O. Stabiana*. Another group requires a slightly drier position and a small proportion of sand in the soil, such as *Calopogon pulchellus*, *Cephalanthera grandiflora*, *C. rubra*, *Cypripedium acaulis*, *calceolus*, *candidum*, *japonicum*, *macranthum*, and *pubescens*; *Epipactis latifolia*, *Goodyera pubescens*, *Gymnadenia conopsea*, *Habenaria japonica*, *H. radiata*, and *H. viridis*; *Orchis mascula*, *papilionacea*, and *spectabilis*; *Serapias cordigera*, and *longipetala*. The third group require to be comparatively dry during winter, but moist at other times, though not wet like the first named, and the soil should consist of loam or peat and chalk. The best for this position are the following: *Aceras anthropophora*, *Habenaria bifolia*, *lutea*, and *chlorantha*; *Neottia spiralis*, *Ophrys arachnites*, *aranifera*, *apifera*, *speculum*, *tenthredinifera*; *Orchis atlantica*, *coriophora*, *longicornis*, *militaris*, *pyramidalis*, and *undulatifolia*. Some of those named for the cool house can also be grown, like *Bletia hyacinthina*, and *Disa grandiflora* can also be grown in cold frames out of doors, and the former has proved hardy in a few sheltered districts. All the hardy Orchids deserve much more attention than they receive, and they are by no means so difficult to grow as some imagine, if strong roots are obtained when dormant, and planted either in late autumn or early spring, the latter being the best if the plants are giving no signs of growth. The greatest trouble is experienced with wild plants lifted when in growth and transferred to gardens, these almost invariably die. Most of the species enumerated can now be purchased cheaply at nurseries, where hardy plants are made a specialty.

## THE DURATION OF ORCHID FLOWERS.

Many Orchids continue in flower for a great time, either from the duration of the individual flowers or their production in succession over an extended period. Some, like *Cypripedium insigne*, last for a remarkably long time when cut and placed in water, continuing fresh for two or three weeks. *Dendrobiums* of the noble character are useful for cutting, as they can be employed in bouquets and button-holes with great advantage, though not lasting so well as the *Cypripedium*. To assist in the preservation of flowers on the plants avoid an excess of moisture in the air, and be careful not to damp the flowers when syringing. Some also remove the pollinia to prevent fertilisation, and where bees are numerous this is advantageous, as the flowers of most Orchids fade almost immediately after fertilisation. The list appended gives the names of a selection of the Orchids which continue longest in flower:—

Orchids lasting eight weeks in bloom—*Vanda Sanderiana*, *Oncidium Jonesianum*, and *Ceologyne ocellata*. Lasting twelve weeks—*Cypripedium Argus*, *C. barbatum*, *C. Spicerianum*, *Dendrobium Deari*, *Lycaste Skinneri*, and *Masdevallia ignea*. Lasting thirteen weeks—*Oncidium tigrinum*, *Odontoglossum cariniferum*, *O. Rossi majus*, *Sophrontis grandiflora*, and *Vanda coerulea*. Lasting sixteen weeks—*Cypripedium Harrisianum*, *Calanthe Regneri*, *Epidendrum crassifolium*, *Laelia pumila Dayana*, *Odontoglossum cordatum*, *O. bictonense*, *Oncidium cucullatum*, *O. incurvum*, *Masdevallia tovarensis*, *Phalænopsis grandiflora*, and *Vanda Batemani*. Lasting twenty weeks—*Epidendrum radiatum*, *O. vitellinum majus*, *Odontoglossum maculatum*, *O. membranaceum*, *Oncidium flexuosum*, and *O. linguæ-forme*. Lasting twenty-six weeks—*Dendrobium bigibbum*, *Masdevallia Normani*, *Odontoglossum Uro-Skinneri*, and *Phalænopsis rosea*.

The *Cymbidiums* also last a long time, and others could be named, but those mentioned will suffice as examples, though one curious instance, *Masdevallia oethoides*, deserve notice, as a plant has been had in flower for five years.—AN AMATEUR.

## ROYAL BOTANIC SOCIETY.

APRIL 14TH.

THE second Spring Show of the year was not quite so large as usual, but the nurserymen's and amateurs' non-competing groups were numerous

and occupied considerable space, most of the former being the same as those at Kensington on the previous day.

Messrs. Paul & Son, Cheshunt, were awarded the first prize for nine Roses in pots, showing handsome healthy specimens, profusely flowered, the best varieties being *Madame de St. Joseph*, *Innocenti Pirola*, *Madame Lacharme*, *Villaret de Joyeuse*, *Souvenir d'un Ami*, and *Alba Rosea*, some of which had several dozen flowers each. The White Baroness was also represented by a good plant, bearing full white or bluish-tinted blooms. The amateurs' prizes for Azaleas were gained by Messrs. Wheeler, W. Wesker, gardener to A. Heaver, Esq., Wandsworth Lodge, Tooting, and H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, for plants of medium size well flowered. In the nurserymen's class for six Azaleas, Mr. C. Turner, Slough, with superbly flowered plants of *Jean Vervaene*, *Duc de Nassau*, *Baron de Vriere*, single, white, large, *M. Thibaut*, *Madeleine*, double, white, good, and *Roi d'Holland*, bright red. Messrs. H. James and Cutbush and Son were the other prizetakers. For twelve *Amaryllises* the same firm was first with extremely bright and varied coloured forms.

*Cinerarias* were not of remarkable merit; they were shown by Messrs. Hill, Phillips, and H. Williams & Son. Both prizes for twelve *Auriculas*, Show and Alpine varieties, were gained by Mr. C. Turner, who had strong plants of the leading varieties.

*Pelargoniums* were staged by Mr. R. Phillips and H. Williams & Son. Mr. T. S. Ware won the first prize for a choice collection of Alpine plants, and Messrs. Paul & Son gained a similar prize for twelve hardy herbaceous plants, also having some good plants, and they were second in the Alpine class with an interesting selection, *Primula nivalis* being especially noteworthy. Messrs. H. Lane & Son, Great Berkhamstead, were awarded the first prize for twelve hardy Azaleas of the mollis type, the varieties brightly coloured and flowers large. The same firm was also first with twelve *Rhododendrons* flowering profusely.

The miscellaneous groups formed much the greater portion of the exhibition. Mr. B. S. Williams, Upper Holloway, had a very choice collection of Orchids, *Amaryllises*, *Imantophyllums*, *Cinerarias*, and fine-leafage plants (large silver medal). Daffodils and hardy flowers were shown by Messrs. Barr & Son, Covent Garden (silver medal); T. S. Ware, Tottenham (small silver medal), and Collins Bros. & Gabriel, Waterloo Road (small silver medal), the exhibits being similar to those at Kensington.

Messrs. H. Lane & Son had a group of *Rhododendrons* and *Azalea mollis* (silver medal). H. Little, Esq., Hillingdon, Uxbridge, had a fine group of well-grown *Lycaste Skinneri*, *Odontoglossums* and *Cattleyas* (silver medal).

Certificates were awarded as follows:—To Messrs. J. Veitch & Sons for *Amaryllises Hedila*, *Pioneer*, and *Crown Princess of Germany*; to Mr. B. S. Williams for *Amaryllises Marshalli* and *Joseph Broome*; to Messrs. E. G. Henderson & Son for *Adiantum fragrantissimum*; to Mr. T. S. Ware for *Cypripedium macranthum*; and to Messrs. Paul & Son for *Dentaria podophylla*.

## DURHAM, NORTHUMBERLAND, AND NEWCASTLE-ON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY.

THE spring Show of the above Society was held on Wednesday and Thursday last in the Corn Exchange and Town Hall, Newcastle-on-Tyne, and notwithstanding the extraordinary season was of a most satisfactory nature. A different method of arrangement was adopted this year. The visitors was agreeably surprised in entering the Exhibition to find three rows of plants in ribbon fashion 120 feet long, the base being *Cinerarias*, next row *Spiræa japonica*, and the top *Dielytra spectabilis*. This has a most pleasing effect, but had the *Cinerarias* been raised a little higher from the ground we think the effect would have been considerably enhanced, and the new feature consisted in placing tall plants and Palms amongst the Azaleas, which was desirable in breaking the monotony of their outline.

The chief prize for plants, £5 and a silver medal, was won by Mr. Ford, Pieremont Gardens, Darlington. *Rhododendron Veitchi*, 6 feet across, well flowered, was splendid; *Genetyllis tulipifera*, one mass of flowers; *Clerodendron Balfourianum*, with every calyx perfect; and the best of all *Erica Victoria Regina*, about 5 feet across, every shoot flowered, and of an excellent colour, the whole forming a quartette, hard to beat by the most skilled cultivator. Mr. Noble, gardener to Theodore Fry, Esq., Woodside, Darlington, was second with *Tetratheca hirsuta*, *Genetyllis Hookeri*, *G. fuchsoides*, and a splendid plant of *Cattleya Trianae*, with eleven spikes, but past its best. Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Darlington, was first with Azaleas—viz., *Oswald de Kerchove*, *Comtesse de Flandres*, *Apollon*. Mr. Ford was second with neat plants of *William Bull*, *Duc de Nassau*, and *Roi d'Holland*. For Palms Mr. Hunter, gardener to E. A. Walker, Esq., Low Elswick House, Newcastle, was first; Mr. J. Morris, Park Filling, being second. The *Deutzias* were an excellent show, Mr. F. C. Ford obtaining first prize, followed by Mr. Joseph Puntun. Mr. Corbett, gardener to E. Liddell, Esq., Benwell Grange, was first for *Genistas*; and for *Spiræas*, which were well represented, the prizes were awarded to Mr. Corbett and Mr. J. Morris respectively. For six *Cinerarias* Mr. J. McIntyre, J. Noble, and Messrs. Kennedy were awarded the honours as recorded; and Messrs. W. Carrick, gardener to E. H. Ryott, Esq., Gateshead, and A. J. Brown for *Primulas*. For *Lily of the Valley* Mr. J. McIntyre and Clark & Co., nurserymen, North Shields, were first and second, in excellent condition. Hardy *Primulas* were as usual good, Mr. W. L. Thompson, gardener to E. Bell, Esq., Wolsington, was first; and Mr. McIntyre showed splendid *Cyclamens*. Table plants were as usual a strong feature, and competition great. Mr. J. McIntyre secured his usual place of first with *Aralia Veitchi*, *Pandanus Veitchi*, *Cocos Weddelliana*, *Croton interruptus*, *Aralia elegantissima*, and *Dracæna terminalis*. Mr. Ford and Mr. Noble following.

For twelve nine varieties of *Auriculas* (Alpines excluded) Mr. W. H. White, Killingworth, was first with *Pizarro*, *Lancashire Hero*, *Sapphire*, *Lord of Lorne*, and *Frank Simonite*. Mr. Garret, Hindling Hall, was a good second. Mr. White was also first in other classes likewise, and for twelve Alpines. For *Polyanthuses* (gold-laced) not less than four varieties, Mr. Wm. Sanderson, Walton, was first with *Earl Beaconsfield*, *William IV.*, *George IV.*, and *Big Ben*. Mr. Edward Adams, Swalwell, was second.

For twenty-four *Hyacinths* Mr. W. J. Watson, nurseryman, Fenham, was

first. The bulbs were prominently shown, and the foliage was firm and of a dense green colour. The best spikes were King of the Blues, Grandeur à Merveille, La Grandesse, Lord Macaulay, Lord Derby, Mont Blanc, Gigantea, and Von Schiller. Mr. J. McIntyre was second, and Messrs. Nairn & Sons, Pilgrim Street, third. For nine pots of single Tulips Mr. Watson was also first with Ophir d'Or, Joost Van Vondel, Keizers Kroon, Fabiola, and White Pottebakker. Mr. J. Short second. There were seven lots staged. For double Tulips Mr. Watson was again first, followed by Mr. McIntyre. The same exhibitor was also first for Polyanthus-Narcissuses; Mr. Short, gardener to Arthur Pease, Esq., Hammersknott, Darlington, and Mr. McIntyre following. There were six lots staged, which formed with the Hyacinths and other bulbs a most attractive display, occupying one side of the Corn Exchange.

Cut flowers and table decorations are generally good at the spring Exhibition, but this year they may be fairly said to have been better than ever. Mr. M. D. Thompson, gardener to Lindsay Wood, Esq., South Hill, exhibited a marvellous epergne for the drawing room. The top tier consisted of Cyrtopodiums, Begonias, Apelelexis, and Spiræas; second tier, Maréchal Niel Roses, Oncidium flexuosum; base, Calla æthiopica, Anthurium Schertzerianum, Phaius grandiflora, margined with Davallia Mooreana, the top relieved with Adiantum gracillimum. Mr. S. Rutherford, Leazes House, Durham, was second with a very good stand indeed. Mr. Adams, Swallow, third. For a bridal bouquet Mr. Hutchison, 58, Collingwood Street, Newcastle, was first with a choice arrangement of Lily of the Valley, Niphetos Roses, American Tuberose, and Gardenia florida; Mr. J. R. Chard, Clapham Common, London, second. The last exhibitor was first for a hand bouquet, containing Bouvardia Hogarth, Stephanotis, American Tuberose, Paneratium, Carnation Goldfinger, and Smith's Yellow Rose. This was an effective bouquet. Twenty-two buttonhole bouquets were staged, Mr. Thomas Laidler, Old Benwell, being first with Maréchal Niel Rose, Spiræa, and Adiantum gracillimum. In the classes above referred to the competition is open to all, nurserymen excepted. Mr. F. C. Ford was first, and Mr. J. Noble second with Azaleas; Mr. Corbet and Mr. Noble with Cytisuses; Mr. Forsyth, gardener to Geo. Cairns, Esq., Monkton Hall, with Mignonette; and Mr. Short and Mr. F. C. Ford with Spiræas and Primulas. Hyacinths, Tulips, Lily of the Valley were all well shown. For an epergne Mr. J. Battenshy, Swallow, was first, and Mr. Whiting, Shotley House, second.

Among the exhibits not for competition was a fine stand of Daffodils from Messrs. James Dickson & Sons, Chester, in which Sir Watkin and General Gordon were prominent. Mr. J. Robson, Hexham, exhibited hardy Coniferae margined with the pretty golden Valeriana Phu aurea. Messrs. Wm. Fell & Co., Hexham, exhibited a collection of stove, greenhouse, and hardy plants, which were effectively disposed.

The first day the weather was cold and unpropitious, but the hall was densely packed at night. The Committee were present with their Chairman, who, along with the indefatigable Secretary, Mr. J. G. Gillespie, were doing all they could in sustaining the interest of the Show, and rendering assistance to exhibitors and the public. The Exhibition was admirably arranged by Messrs. Wilson, Balfour, and Gascoigne.

### CINERARIAS AND THEIR CULTURE.

WHEREVER Cinerarias of a good strain are represented by really well-grown plants they are certain to command a host of admirers at this season of the year, and I know of no class of plants likely to give such general satisfaction from January till April. Flowers of the improved types have such great size and substance as to leave but little to be desired in that direction. There is also such great richness in many of the colours in the way of purples, crimsons, and magentas as few other flowers possess. If we could only get a yellow as rich as an Allamanda, and a scarlet as bright as Vesuvius Pelargonium, the range of colour would then be well-nigh complete, but perhaps through the efforts of our skilful hybridists and enterprising nurserymen these may be obtained in the future. Plants in various sized pots are useful in many ways, either for supplying cut flowers or for house and conservatory embellishment; for the latter purpose they are invaluable, especially where large houses have to be kept gay, as when once the flower buds begin to show colour it is not at all necessary to keep the plants near the glass, for they will develop their blossoms when placed many feet from the glass as well as if kept close to it, which is a matter of some importance in large houses. With all these good qualities to recommend them, Cinerarias do not appear to be grown in such quantities as I think their merits deserve. True, we generally see a few plants in any garden where there is a glass structure, and in such cases there is only room for a few, but in larger establishments, where plenty of pits and frames are at liberty for growing them during the summer, and suitable structures for their reception in autumn and winter, they would, I am certain, give greater satisfaction if enough were grown to produce a distinct feature at a certain time than can be obtained by the various mixtures of plants that are often grown, and which, in many cases, cannot have the special treatment the different classes require. The culture of the plants under notice is by no means difficult; nevertheless, like most others, to have them in really creditable condition they require a considerable amount of time spent upon them, and constant attention to the various details connected with their cultivation. Cinerarias are great favourites here, and are consequently grown rather extensively, some three or four hundred plants being required, hence my reason for supplying an account of their treatment, thinking it might be interesting to the readers of the Journal, and also hoping it may be the means of inducing others to grow them in greater numbers.

#### [SOWING THE SEED AND TREATMENT OF YOUNG PLANTS.

The first sowing, to supply plants for flowering in 9 and 10-inch pots, is made about the beginning of April, and another sowing at the end of May to obtain good useful plants in 5 and 7-inch pots. Our practice is

to sow in ordinary seed pans, about 3 inches in depth. One crock is placed over the hole at the bottom, a layer of medium-sized ones over that, which are in turn covered with very small crocks, so as to leave the surface perfectly level. Over this are placed the rough parts of the leaf soil that has been used in preparing the soil in which to sow the seeds. After this operation is completed the rough material over the crocks should be  $1\frac{1}{2}$  inch from the rim of the pan; that will allow room for the soil and a quarter of an inch between it and the glass that should be placed over the top of the pan. The soil we use for the purpose consists of equal parts light loam and good sweet leaf soil free from insects, and little finely powdered charcoal and fine sand added, and the whole passed through the quarter-inch sieve, and well mixed together. A portion is then pressed firmly into the pan already prepared, a little of the same kind of soil is mixed, passed through a fine hair sieve as it is held over the pan, and is then made smooth and firm, which leaves a good surface on which to sow the dust-like seed, but before doing so it is a good plan to place over the soil a very slight sprinkling of white sand shaken through the hair sieve. The seeds can then be seen much better as they are scattered on the surface and consequently can be sown more evenly. It is a great mistake to sow the seeds thickly, because the young plants become too much crowded before they are large enough to be pricked off. After the seed is sown we give a slight covering of finely sifted soil, press it slightly with a smooth board, and give a slight watering through a very fine rose. A square of glass is then placed over the pan, which is placed in a warm vinery and shaded with moss or paper till the seeds show signs of germinating. The shading should then be removed, and as soon as the young seedlings become injured to the light place them in an open position near the glass, where they will require no shading till pricked off. I have found it a great advantage to keep the square of glass still over the pan, but it should be kept a little above the rim by means of two pieces of crocks so as to allow a current of air to pass over the plants.

Treated in this way the plants will make rapid progress, and as soon as they are large enough should be pricked off 1 inch apart in shallow well-drained boxes, in soil similar to that in which the seeds were sown, pressed firmly and finished off with a thin board, and as each box is filled with young plants, watered through a fine rose to thoroughly settle the soil about the roots. A capital place for them at this stage is around the sides of a Melon pit where Melons have been recently planted, fixing shelves to keep them near the glass, and shading from bright sunshine. When the plants have grown sufficiently for the leaves to touch each other, and before they become crowded, place them into small 60-pots. At this first potting do not press the soil too firmly, and take great care not to wring the collars of the plants, or they will be liable to die, especially if by any means they should get too wet. This rule should be observed at all subsequent pottings, as many Cinerarias are lost from this cause alone, although it does not account for the mysterious dying of plants in various stages as is often seen. These causes I will refer to later on.—A. DUNKIN.

(To be continued.)

#### KITCHEN GARDEN.

THE weather continues very changeable, and we have not made the progress in vegetable planting we anticipated since the frost left, but we would rather be a fortnight late in sowing than attempt it when the soil is unfit, as late-sown crops always prove satisfactory, but those sown in wet soil are the reverse.

**RADISHES.**—In large gardens these must be supplied all the year, or as near that as possible; but in small ones they are only cultivated to come in from early summer until late autumn, and where this is the case a sowing of French Breakfast should be made at once. They will grow quickly now, and the first of them will be ready for drawing in from three to four weeks. From the time the first are gathered from a patch until they become stringy is generally about a fortnight, and no more should be sown than there is likely to be a demand for during that time, and by sowing the same quantity once a fortnight a constant succession of tender sweet roots will be produced. Varieties of Radish are very numerous. Many of them are pretty, and all are good when properly grown. The Turnip-rooted ones are the best for shallow soil. In the early spring a sheltered sunny spot where the soil is rather light suits them best, but as the weather becomes warmer a cool soil and situation should be given them. They delight in a rich soil, but dislike rough lumps of manure.

**LETTUCES.**—A patch 2 feet or 3 feet square sown with seed will furnish many scores of plants, and it is a mistake to sow them in too large quantities, as they are apt to run to seed early in hot weather, and small sowings made often is the best way to secure a constant supply of tender crisp heads. They should have rich soil at all stages of their growth, and care must be taken that they are not eaten by snails. Lettuce sown last autumn and wintered in a small state to supply heads early in spring, are now almost ready for cutting, as they were protected during the winter, and others to succeed them which were raised under glass in

spring should be planted out as soon as possible. As yet they should be put in sheltered positions, and none be put out which are not well hardened. Our favourite place for Lettuce culture in summer is on the top of the ridges between the Celery trenches.

**TOMATOES.**—The earliest plants were shifted into pots and boxes some time ago. Some of them were placed on the back shelf of a Pine pit, others into the Cucumber pit, and some in a cool house. Those in the Pine stove are heavily laden with fruit, those with the Cucumbers are not quite so forward, and the others in the cool house are later still, but they are very robust, and will probably be the best in the end. The early ones now maturing their fruit are being kept very closely pinched in, and liberal quantities of liquid manure are given them. This is a sure way of making the fruit swell quickly and to a good size. Young seedlings which are being brought forward should be potted singly before they are injured by being crowded. Others in small pots with a great many roots should be given more root room, as it is very injurious to stunt them early in the season, or when they should be growing freely. Plants intended for open air culture are about 1 foot in height, and they must be hardened by being placed in a cool frame as soon as possible. The great secret of successful open air Tomato culture is to have strong healthy plants to deal with at planting out time, and unless this is the case it will be so late in the season before the fruit ripens that the crop will be light and of short duration.

**CARROTS.**—Those sown in the open air before the severe frost of March have shown up very well of late, and the border of Early Horns is all right, but the main crop has not been put in yet, and it should be sown on an early date. James' Scarlet Intermediate or others of this type is the only variety we grow for the main crop, as the roots do not require a very deep soil, while in quantity and quality they are all that could be desired. This crop should have one of the best spots in the garden, and previous to sowing the ground should have a good dressing of soot, and then fork it in. The rows should be from 15 inches to 18 inches apart and 2 inches in depth. After covering the soil should be finely raked, and then rolled hard. Good roots always follow from this practice, and insects are not half so troublesome in the soil when it is firm than when very loose.

**BROCCOLI.**—Make two sowings of these, and the first may be put in now. We have sown seed of Veitch's Autumn Protecting, Osborn's Winter White, Backhouse's, Cattell's Eclipse, Leamington, and Sutton's Late Queen. Other sorts will be sown in a day or two, and part of each will be sown in a fortnight or three weeks hence. Good soil is very necessary to produce healthy free-growing plants, and they may be sown in rows across a border or in patches anywhere. We sow ours in a narrow border along the side of one of the kitchen garden walks, and they always do well. We prefer them in rows to broadcast, and make the former from 8 inches to 10 inches apart. The seed should not be sown thickly and about 1½ inch below the surface.

**PARSLEY.**—Make a good sowing of this, as the plants raised at this time will keep a supply of the much-valued leaves until next spring. We never found Parsley fail where Carrots succeeded, and if several rows are put in at the same time as the Carrots a good supply will soon be forthcoming.

**VEGETABLE MARROWS.**—The remarks above on ridge Cucumbers apply to these. Where quality is desired sow the Pen-y-byd variety. If size is the object grow Long White.

#### FRUIT FORCING.

**VINES.**—*Early Houses.*—Examine the Grapes, and if any of the bunches are too crowded remove a few of the least promising berries with a pair of finely pointed scissors. Keep the soil of the inside border in a moist state until the Grapes are ripe. Choose a bright fine morning as the best time for watering, and admit air rather freely, so that all superfluous moisture will disappear before ventilation is reduced for the day, and to prevent its escape from the soil a little fresh mulching or short stable manure may be spread on the surface. Ammonia arising from the stable manure in combination with stimulating liquid to the roots will keep red spider in check. It, however, will attack even when the most effectual precautionary measures are taken, and to keep it from spreading there is no better plan than to carefully sponge the leaves with a soft soap solution, 2 ozs. to the gallon of water, which, though a tedious, is an excellent remedy for its removal. Painting the hot-water pipes with sulphur brought to the consistency of thin paint with skim milk is also a good remedy, but it is well to apply it to the return pipes only, and not to give a very thick coating. The fumes of sulphur are very injurious to delicate-skinned Grapes, particularly so to Frontignan and Muscats. Ventilate night and day when the berries begin colouring, and increase it as they approach ripeness, but fire heat must not be entirely discontinued, though the temperature is to be gradually reduced, sufficient being afforded to maintain a minimum of 60°, as the Grapes will improve in quality after they are considered fit to cut, the last out being often better than the first.

*Muscats.*—Houses of these and other shy-setting Grapes when in bloom will require a high temperature by day, with a good circulation of air and a fair supply of atmospheric moisture to prevent the young foliage suffering under the influence of bright sun. Fertilise with Hamburgh pollen if it can be obtained, and in the middle of the day when the atmosphere is buoyant. A temperature of 70° at night is easily maintained in inefficiently heated structures, but with roots active a temperature of 65°, or even 60°, with a little air is more satisfactory than hard firing to maintain a given temperature in all weathers.

*Late Houses.*—Make the most of solar heat for pushing on late Vines as Lady Downe's, as all long-keeping Grapes cannot be over-ripened if they are to be kept fresh for some months after they are removed from the Vines. Commence ventilating early on fine mornings, and allow the heat to rise to 80° with increased ventilation and plenty of moisture, closing in time for it to rise to 90° from sun heat on fine afternoons. A night temperature of 60° will be sufficient until the Grapes flower, when 5° more will be necessary to increase the length of the bunches and produce conditions favourable to the setting of the fruit. All late Grapes do best when planted inside the house with the run of outside borders, which should be elevated, well mulched, and exposed to all the rain that falls from the time the Grapes are cut in January until the succeeding crop is ripe in the September following. As a rule, all late Grapes require artificial impregnation. For removing the glutinous substance from the stigmas a camel-hair brush is best, and the matter allowed to remain will prevent the berries from setting, whilst its removal insures their setting freely.

**CUCUMBERS.**—These are now plentiful in most gardens; the chief object is, therefore, to maintain a good supply throughout the season, which can easily be done by attending to the stopping, thinning, and cropping of the plants, with an occasional top-dressing of light loam, to which a third of short well-decomposed manure has been added. Copious supplies of water must be given to the roots when necessary, some requiring it daily, others bi-weekly, weekly, or less frequently, according to special circumstances, as plants growing in narrow borders with plenty of drainage, and having the bottom heat supplied by hot water pipes, with the plants in full vigour there is little fear of too much water being given, whilst with plants growing upon a bed of fermenting materials, and having more scope for root-action, the plants require very little water at the roots. Syringe twice a day during bright weather. Ventilate freely on all favourable occasions, avoiding cutting winds, striving to secure a short-jointed and consolidated growth. Keep the plants free from the attacks of red spider, green and black aphides, by a proper use of the syringe.

**MELONS.**—The earliest fruits are approaching maturity, and the plants will need syringing less frequently; and in damping the plants and house avoid wetting the fruits, as that would cause them to crack; in fact, a somewhat dry atmosphere is essential when the fruit is ripening. To have highly flavoured and finely finished fruit the cleaner and healthier the plants are at the ripening period the greater is the probability of its being effected. Besides, when care is taken to keep the plants healthy a second crop may be allowed to set, which by the time the first crop is ripe will be considerably advanced in swelling and without any detriment to the first, all male and female flowers being removed after a sufficient number of fruits have been secured for the crop, with the usual stopping attended to. After the ripe fruit is cut stir the surface of the bed, tread, and add more soil if necessary, watering with clear tepid water thoroughly, and follow at once with a copious supply of liquid manure. Keep well syringed, and a full second crop of fine fruit will be obtained. Melons in successional houses, pits, and frames will require daily attention in stopping, tying, and thinning of the shoots and impregnating the blossom in the middle of the day when the pollen is dry, acting upon all expanded flowers at the same time in order to secure a regular set, so that the fruit left may still be distributed regularly over the principal shoots of each plant and swell together, and so insure uniformity in size. Plants should be prepared for planting in pits and frames as they become cleared of Potatoes, &c. Houses that have been used for winter Cucumbers, and these being dispensed with, the houses should undergo a thorough cleaning preparatory to planting with Melons. Wash the woodwork with soap and water, using only clear water for the glass, and well limewashing the brickwork. Use good turfy loam, with a tenth of old mortar rubbish and a sixth of road scrapings, and if the loam be very stiff some charcoal may be added to render it more porous, but burned clay in the same proportion as the road scrapings is preferable. This should be placed in a few days to warm; press the soil firmly around each plant. Sow for succession according to requirements.

## THE BEE-KEEPER.

### QUEEN-RAISING.

HOWEVER much bee-keepers may differ on many points connected with bee-keeping, on one point at least they are all one, and that is, that in order to have all hives in a prosperous condition young queens are essential.

Among the old bee-keepers not much attention was paid to queen-raising, the stocks swarmed in the natural way, and old and young queens were consigned indiscriminately to the sulphur pit, and the heavier the stock at the end of autumn the more certain its doom. Just as we should not expect to get strong lambs from a worn-out ewe, so neither can we expect to get populous colonies from aged queen bees. The duration of the life of a queen bee depends very much on the number of eggs she lays in a season. In a small hive a

queen may live four or five years, and may still lay a large number of eggs, but in large hives she is generally useless after the second year, and unless she is of some particular strain, either English, foreign, or hybrid, we always get rid of a queen at the beginning of the third season. In a small apiary queen-raising hardly pays, as it is cheaper to buy young queens, or, if we can get the chance, the second swarms or casts.

But as our apiary consists of some twelve to twenty hives, we always rear our queens in the following manner. Having carefully selected the strain or strains we wish to perpetuate, we place bars containing sheets of foundation in the centre of the brood nest, but not before the middle of May, or even later if the weather is cold. We then select one of the strongest of our hives, have a small artificial swarm, and remove the old hive to a new stand, giving the swarm two or three bars of brood from the old hives or from others.

The queenless bees immediately start several queen cells, and on the fourth day after they have been deprived of their queen we cut out all the queen cells and place in the centre of the brood nest two or more bars of selected brood, and in order to induce them to make queen cells make slits in the new comb containing the eggs and grubs. Some of the Italian queen-raisers carefully remove alternate eggs, but we have never tried the plan, though, no doubt, it is a good one, as the economical bees do not, unless driven by stress of hunger, destroy eggs. If there are as many queen cells as are wanted, we do not add any more brood for queen-raising, but keep the hive populous by giving them another bar or so of brood. Sometimes it happens that only a few queen cells are started, and in that case we give the bees another bar or so of selected brood, and so get the required number of queen cells.

When ten days have elapsed from the time the queen was taken away, we proceed to make small nuclei, either by making artificial swarms without a queen but with brood, or by putting the nuclei on the stands of the old hives and, of course, giving them some brood. In two days time we insert a queen cell in each nuclei, taking care to cut quite clear of the queen cell. In the course of a few days the young princesses will be hatching out, and great care has to be taken that the bees do not follow them in their nuptial flights. Still if the nuclei have brood, it does not often happen that all the bees leave the hive, but if they do the swarm has to be taken and replaced.

During the course of the next few days we examine the nuclei occasionally to see if the young queens have begun to lay, which is carefully noted in a diary. The fertile queens are then introduced, but we will defer the method of queen introduction to a future article.—A SURREYSHIRE BEE-KEEPER.

### THE EFFECTS OF WINTER ON BEES.

THE present is perhaps a most fitting time to lay before your readers the effect the protracted winter has had upon bees, and so give them an opportunity of comparing the results of their own experience with ours, thereby enabling them to rectify evils or to pursue and establish a system based upon common sense, which they have found to work satisfactorily towards preserving bees and to the profit of the bee-keeper. Although it is now the 2nd of April there has only been two days that the temperature was high enough to feed bees with safety without causing loss, owing to the cold and windy state of the weather. The two days mentioned were occupied and required by the bees to thoroughly air themselves. None of my stocks required feeding, therefore was not in the least put about, relying upon the arrangements I made in autumn and past experience, which, I am glad to say, have no apprehensions but that they are safe and will continue so for weeks yet without any assistance.

I have had one death only. It was a pure Syrian, a nucleus containing very few bees; but several nuclei of Carniolians with fewer have wintered well and are promising well. Another pure Syrian lost most of its bees, but is busy cleaning out, carrying pollen—or rather pea meal, for as yet few flowers are out, while others from the extreme cold refuse to shed their pollen or open up their anther cases. The pure Syrians apparently cannot stand

our climate. The crosses do, and seem no way impaired for their work by the accident.

With the above exceptions all the rest of my hives have wintered well, with less loss than I have witnessed in milder winters, every one without exception having bred since the end of the year, and every one has much of the youthful element and in a fit state to store surplus honey, appear when it may. Those in deep hives as usual remained quietest during winter, most of them never sought out during the snow. Had the spring been earlier I should have reduced the size of my Stewarton hives by removing the under box, but already they occupy the two upper ones, and to lessen the hive now would be courting failure.

Much stress is put on double-cased hives by some. With me there is no difference; if there is, the single-cased hives are the best when well protected. Deep hives, having always the honey above in the natural warm strata, it never suffers from cold and damp as it does in wide flat hives, hence the bees have always a meal of a proper heat of wholesome honey, having access at all times to it through a congenial atmosphere; never requiring to creep aside to the outer combs in the cold where death awaits them, as is the case with those on the combination principle; not requiring to travel round the combs or having "winter passages" artfully cut through them before they can reach their stores, as the flat hives have; and the bees, from the excitement brought about by their attempting to raise the heat, by eating cold honey and entering a cold atmosphere, fly out every feed they take or movement they make. Thus bees in flat hives are decimated or die from starvation when they cannot travel to the adjoining combs for honey, while those in deep hives are safe and healthy.

From time immemorial bee-keepers in Scotland have always held that hives to be healthy must have their combs at right angles to the entrance; and Mr. Woodbury, than whom there is no better authority, put this to a thorough test many years since, and recorded his experience in this Journal to the effect that bees to be healthy ought to have their combs situated at right angles to the entrance. In all he said on that subject I agreed with him, and thought it a foregone conclusion. But a new era in bee-keeping dawned upon us, and we were told we were on the wrong track, and that to be successful hives having their combs parallel to the entrance should be used. In order to satisfy bee-keepers and prove the contrary to them I had several hives with their combs so arranged, but just as Mr. Woodbury explained, and in accordance with my previous experience, the bees refused to live healthy during winter, so I abandoned the idea for ever.

There has been a great mortality amongst bees this year, and I have exerted myself a little to get at the facts, such as what condition were the hives in and of what sort were they. The first news of disasters reaching me were the bees were located in combination hives, the bees had suffered from dysentery, and now all were dead. I have several hives of that sort under my superintendence for an acquaintance: they, too, have paid the debt of Nature prematurely. Other casualties arose from keeping the bees on a stinted allowance of food, so that the "orthodox" plan of stimulative feeding and spreading of the brood should be carried out, but the bees had succumbed for want before the weather was favourable for feeding. Others having hives similarly provided saved the bees from dying inside by feeding them, and thereby bringing them out to perish amongst the snow. Whether these salutary lessons will prevent their erring again remains to be seen; but one thing is certain—had they taken my advice to put their bees up in autumn with 30 lbs. of honey there would have been fewer deaths amongst them than has been this arctic winter, and we have no assurance that the like will not occur again. We have experienced similar winters before, and we may expect them again.

There is still another singular notion bee-keepers have in regard to the size of the hive and its condition. I read lately the cogitations of an advanced bee-keeper, "Ideal of a stock when ready for supers is that it should be filled with brood or eggs from side to side and top to bottom, excepting at most a few days' supply of food in case of a serious reverse of weather." To my mind this is the rock many bee-keepers wreck themselves on. A hive should never be in such a state. It should be large enough to hold at least 30 lbs. of honey and at least one comb, and better two, of pollen over and above what will hold 60,000 eggs or larvae, with additional space for water and unsealed honey, which every healthy and progressing hive has. Such a hive as that, containing a healthy, fertile, and prolific youthful mother, is our ideal of the only hive that will give satisfaction.

The same writer too, as well as others, seems of the opinion that whenever you have a sealed comb in the hive it ought to be uncapped and placed in the centre of the hive to be filled with eggs. But why all this waste and labour? Surely it would be far better for all purposes to keep the queen from the supers, keep the bees breeding, and allow no waste of eggs, &c., by having the hive of a

proper size at first, and save the waste of honey and strength of bees. If bees are restricted in carrying on the internal economy of the hive to the full extent for the purpose of getting all the honey stored in supers, which is bee-keeper's arguments, it is but another way of "killing the goose that lays the golden egg." The hive that allows of a surplus of 40 lbs. in the stock hive will collect far more than that extra than the restricted ones, while the honey is superior. If our bees have come through the winter unscathed my flowers have not. Roses are browned to the ground, Primulas and choice Polyanthus, &c., killed, and the hardy Sedum fabarium is nearly killed.

Wasps seem likely to be very numerous this season, notwithstanding the cold summer and autumn. Some piled wood I saw turned over lately had many thousands ensconced between the boards. In years long past I have gathered shovelfuls from similar places. If gardeners would pile up in August some boards in this fashion, so that the wasps could creep in under, I could not suggest a more destructive plan on wasps and with less expense and trouble than the above. The only caution required is that the boards are under cover but open at the sides.—A LANARKSHIRE BEE-KEEPER.

### BEE MANAGEMENT.

I SHALL be grateful if you will kindly answer a question or two on supering bees. I have some wood boxes which I have used as supers, with glass on one side, with lid to close down. They are 12 $\frac{3}{4}$  inches by 11 $\frac{3}{4}$  clear inside, by 7 inches deep, and will hold exactly eighteen sections—that is, touching each other, except with just room enough for a piece of zinc to go between each row lengthways. Is it necessary to have a passage between the rows lengthways for the bees to pass, or crossways? Of course they will be able to pass underneath, as the sections will rest on longitudinal bars, and they can also pass between section and section top and bottom. I propose to have one side of box, opposite glass, to let down by means of two small hinges, and fasten up by hook on each side to facilitate removal of sections. I have never used sections, merely these boxes placed on top of other boxes as supers. My lower boxes are 16 inches square by 11 inches deep, clear inside, and stand on two rows of shelves inside a house with 6-inch clay walls and thatched roof; the bees pass out through the wall, and can't enter the house. Why I am about to try sections, is the difficulty in making the bees work up into these plain boxes. Any remarks you may kindly make will be thankfully read in the *Journal of Horticulture* by yours truly.—H. T. H.

[The boxes are a very unfortunate depth—too deep for one tier of sections, and not deep enough for two; they may, however, be cut down to the required depth without any great difficulty. The sections it is intended to use appear to be the ordinary 1 lb. ones, measuring 4 $\frac{1}{4}$  by 4 $\frac{1}{4}$  by 2. It will be a problem not very easy to solve how to place eighteen of these sections in a box measuring 12 $\frac{3}{4}$  by 11 $\frac{3}{4}$  inches, inside measurement. They may be placed, as intended, three abreast, but six rows will in that case be necessary, and six multiplied by two making twelve, and room for separators having to be left, it is quite an impossibility to put more than five rows in such a box. This is, of course, not material, but it will be better to give up the idea of a hinged shutter, and place a loose board along the outside surfaces of the extreme sections in the same manner as a separator, but not admitting the egress of any bees. The lid may be dispensed with, and some warm covering provided to retain the heat and prevent the escape of bees. The space left by the longitudinal bars upon which the sections stand, if such bars are made at least three-eighths of an inch thick, will provide a sufficient means of entrance to the sections, and no other will be required. Separators cut in the manner described will be suitable provided they are cut so as to leave a bee space—that is, room for the passage of the bees from section to section without difficulty both at top and bottom. Many bee-keepers leave half an inch, some a little more, some a little less.

The necessity for the sides of the boxes, which it is intended to transform into racks, and the sections to be co-equal in height, will be very evident when it is remembered that as soon as one rack is taken possession of by the bees, and comb-building is going on extensively, another must be placed either upon or beneath the one already in the hive and being worked by the bees. The glass end will be useful to ascertain the condition of the rack, but it is well not to forget that the outside ones are those last sealed, and are, therefore, not quite a sure index to the state of inner combs. The shutter is an awkward contrivance, and the loose board is for many reasons preferable, the bees will not fasten the sections together so as to make manipulation difficult. The grand secret is to have well made and good fitting racks, and then the necessity being taken away, propolis is reduced to the least possible amount. The hives are not of the fashionable dimensions, but ought to yield a good harvest of super honey in a season of average honey weather.

It is a mistake to imagine that bees will enter and work sections more readily than large supers. Rather the reverse is the fact. One of the most frequent objections urged against the use of sections is the apparent unwillingness of the bees to enter them. Few instances—in my own observation none—occur in which bees refuse to enter supers of any description if the stock is in a proper condition for receiving an extension of room, and the weather is favourable. Strong stocks filled with brood and bees and honey will enter supers, weak ones will decline to annex

new territory while the old one is only partially occupied. [Crowded populations want extension, not thin ones, which possess already more room than they are able to fill. Those who cannot get bees to enter supers placed at the proper time fail because their stocks are too weak. Strong stocks are absolutely essential in profitable bee-keeping. The house in which the hives are placed being formed of clay and thatched will be warm, but it is not a necessity to have such an elaborate dwellinghouse, and there is a danger of mice, moths, and other bees' enemies harbouring in it and committing depredations. With care no harm will happen, with negligence great mischief may be done in a short time. One point is often overlooked in such constructions, and that is that insufficient alighting boards are too often given, with the result that many bees are destroyed which might if a proper projection had been attached have lived to work for weeks instead of dying thus within sight of home. Attention to this point will give great satisfaction to anyone who has observed the bees formerly in rain attempting to reach the board on which, mainly owing to its very slight projection they were unable to gain a foothold, pass in with safety.—FELIX.]

RUTHERGLEN HORTICULTURAL AND APIARIAN SOCIETY.—As the name of this Society indicates, the Committee recognise the natural connection that exists between flowers and bees, and while prizes are offered for fruit, flowers, and vegetables, apiculture is encouraged as well. There are twelve classes in this section, prizes being offered for honey, hives, appliances, comb foundation, &c., no less than eight silver medals being provided as awards to the most successful exhibitors, including the Highland Society's medal for the best and largest display of run honey and honeycomb. The prizes appear to be open to all, and we trust the twin exhibition to be held on September 3rd will be very successful. Mr. Ebenezer M'Nally is the Honorary Secretary.

### TRADE CATALOGUE RECEIVED.

Thomas Pointer, Smallwood, Stoke-on-Trent.—*Catalogue of Dahlia Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

Size of Lawn Tennis Courts (F. W.).—The length of a tennis court is 78 feet; width for a single court, 27 feet; double, 36 feet.

Everlasting Flowers from Seed (J. A.).—Ammobium alatum seed may be had from all the leading metropolitan and provincial seedsmen who advertise in our columns. We do not think seed is sold of the other you name, but plants can be had from nurserymen. Acroclinium album and white Heliclysums are easily raised from seed, which is sold by nearly all vendors of flower seeds.

Royal Horticultural Society's Reports (Mrs. P. E. W.).—The reports in question are not published at this office. You had better write to the Secretary of the Society at South Kensington, and he will give you information on the subject. Some of the reports, we believe, are not sold, while others are.

Lime Rubbish for Vine Border (J. C., Somerset).—We certainly do not consider you troublesome; it is a pleasure and not a trouble to us to impart information that may be of service to inquirers. You have probably decided rightly in making a new border and planting young Vines next spring. Save all the lime rubbish, as it will be of great service in making the borders. Be careful in excavating and concreting that you do not

make a water tank. Concreting is worse than useless if not made with a sharp slope and drains provided for the free exit of water. You had better describe the site and subsoil some time before commencing operations, and we shall be glad if we can give you further advice on the matter.

**Mildew on Strawberries (A Reader).**—The great difference between the day and night temperatures and the action of cold on the tender foliage with, at the same time, a damp atmosphere favours the spread of mildew, and there are probably sharp currents of air through your improvised frames. As you have the means of shading the plants in the daytime you can also cover the glass at night, thereby arresting radiation and securing a more equable temperature. We suspect you do not admit air soon enough in the morning. Early ventilation and early closing is the right principle to adopt. On the first faint signs of mildew dust the foliage with sulphur, keeping it off the fruit. There is a fault somewhere in your method of ventilating. We will send your letter to Mr. Bardney as you request his opinion.

**Boiler Leaking (Horace).**—Ten years is not an average length of time for a saddle boiler to last. We presume the boiler is a cast iron one, and if so it will be difficult to repair. If a wrought iron rivetted boiler it would be more readily repaired; the advisability, however, of repairing can only be determined by an examination of the boiler, and ascertaining the nature and extent of the damage. If the boiler is so damaged as to cost a considerable sum in repairs, being thin from corrosion, then we should decide in favour of a new boiler. Select one of the improved form of saddle, those with a waterway check end and side flues being preferred by many gardeners. A wrought iron rivetted boiler is more costly than a cast-iron one, but is durable, repairable, and economically heated.

**Violets (Young Gardener).**—Violets are now so numerous and the varieties so much alike, especially several of the Neapolitan varieties, that it is extremely difficult to make out their distinctive characteristics from a plant in full foliage and flower, and the difficulty is still further increased when only leaves and flowers in a cut state are examined, whilst it is impossible to be definite about their names when flowers only are submitted. The darkest coloured flower of those you sent is probably New York (syn., Marie Louise, of some), the flowers of which are irregularly splashed with red more or less at the base of the petals. It is the best of all the Neapolitan forms of Violet for autumn and winter to spring flowering. The light flower is probably De Parme, the very best of the light coloured forms of Neapolitan, and very distinct. The flowers, however, were much crushed in passing through the post. If De Parme the plant will be very compact in growth, and flowers will commence appearing in September; but if Neapolitan (old variety) it will not flower much until spring, and be prone to throw off many runners. The flowers are not very dissimilar, but the De Parme is much the best. The true variety of Marie Louise has a similar flower—viz., pale lavender with a white eye, and it flowers profusely from September to April, and is one of the very best and scarcest of Violets, being difficult to keep true through its sporting into the varieties that have the red splashing on the petals near the eye—the only difference between them. Judging from the flowers in the small bunches you sent us without foliage, we think they are as stated—viz., New York and De Parme, dark and light respectively.

**Making Vine Border (C. C. C.).**—If there is no water in the sand beneath the loam the necessity of drainage will not arise; but if there be water, as there frequently is in sand, it will be necessary to put in pipe drains so as to carry off the superfluous water, the drains having proper fall and outlet. In addition to these you will require a foot in depth of drainage, which should consist of brickbats or other material broken up, putting the roughest at bottom and smallest on the top. It would be well to cover the drainage with a layer of turf grass downwards. By mixing a sixth of old mortar rubbish with the strong loam and a similar quantity of horse manure, is likely to make a suitable compost for Vines, the whole of the materials being well incorporated. If the soil is deficient of gritty matter, add a sixth of road scrapings. Two feet six inches is a suitable depth of border. The whole of the soil will need to be taken out, thrown in a heap for mixing with the other ingredients. You will require five barrowfuls of the loam, and one each of lime rubbish, horse manure, and road scrapings, to which you may, if you do not mind the expense, add half a bushel of half-inch bones, the whole to be thoroughly incorporated. If you can procure turf from a pasture where the soil is a light loam, and taken off about 3 inches thick, it would be preferable, omitting all the other ingredients except the lime rubbish and bones, and putting in a tenth only of the lime rubbish and half a bushel of bones, the turf being chopped up moderately small, and the whole well mixed. Good Grapes, however, are grown in ordinary soil, the chief thing is to make sure of thorough drainage, and to add sufficient lime rubbish and gritty matter to keep the soil open. Cow manure will be valuable as a surface dressing, but it ought not to be mixed with the soil. A 3 foot width of border will be sufficient for the first year. You may plant the Vines in May, and properly attended to they will make strong canes by autumn. The moss litter manure from stables is suitable for growing Mushrooms. A grower informs us that he had an abundant and paying crop from the employment of such litter on which hunters had stood, the beds being outside, and the instructions followed as given in "Mushrooms for the Million." You may have an abundant crop of Tomatoes in the house this season with good management.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (R. P.)—We cannot tell from the small withered flower and imperfect description, but perhaps it is a *Streptocarpus*.

#### COVENT GARDEN MARKET.—APRIL 14TH.

#### PERMANENT PASTURE.

DURING the present month much grass seed is sown either for layers or permanent pasture, and attention may therefore well be called to the consideration of ends and aims in this work. Consider the end, always consider the end, say we, and weigh well every detail of work and probable results before coming to a decision about it, but when this is done bring all possible energy and skill to bear upon the work, and be satisfied with nothing less than the best way. There is by far too much inferior work in agriculture, and this is owing to various causes; insufficient capital, ignorance, prejudice, and thoughtlessness are other causes.

Let us see now what can be said for and against permanent pasture regarded from a general point of view. It may be laid down at the outset that an average crop of two tons of hay per acre may always be had upon really good permanent pasture. Last year we had almost double that quantity from some of our best pastures; nor was this simply owing to a favourable season, but rather from steady persistence in the use of the manures we have so often enumerated in articles on this subject. The lowest price now for

good meadow hay in the rick is £4 per ton; cut, tied in trusses, and delivered to the consumer it readily commands another £1, but at the lower rate we have £8 per acre for hay alone, with an aftermath available for grazing by cattle for three months after haying, or for sheep onwards till the following February or March. At the present low value of land £3 per acre will pay rent, tithes, taxes, as well as for manures and labour, and if so, can we say that profitable farming is impossible?

How to obtain such pasture is, we fear, beyond the knowledge of the ordinary farmer, simply because he has never set himself seriously to become master of a branch of farming, which high prices for corn enabled him to ignore. At a market town in the eastern counties a so-called lecture on permanent pasture was given recently, which really resolved itself into an enumeration and description of the most suitable sorts of forage plants for the purpose. In the subsequent discussion of the subject the questions and remarks of the farmers made, it was quite evident they were incompetent to undertake such work. Ten shillings and 20s. an acre were sums mentioned as a sufficient outlay for laying down land to permanent pasture, and outspoken preference was given to a growth of natural (indigenous) Grasses. Such observations are an undoubted outcome of ignorance, and, we fear, we must add some prejudice. Evidence of this might be enumerated from many sources, one remarkable example must suffice. A correspondent of the *Agricultural Gazette* recently gave utterance to his views by the following remarkable statement:—"I must have a word about seeding of land down to grass. Our prodigality knowing ones will have it that the laying of land down to grass needs a costly process of cleaning and seeding with cracked-up seeds. I have examined a lot of land that has been seeded down thus costly, but in no one instance do I find their grand costly seeds to stand. They die out, and the natural Grasses come in. My own 100 acres of clay land that run down takes the shine out of the costly practice of seeding down, for it is now overrun with natural Clover and other fine Grasses. I did not have any of their pickpocket stuff, but I dress my land frequently with corn-made manure. That is the way to fetch the land about." This proof of the pudding so positively set forth, probably led to its publication. No doubt the term "run down" is singularly appropriate, but can farmers afford to let land for which they pay rent run down? Can they afford to adopt such haphazard practice as to trust to a chance growth of natural Grasses? The writer of the statement is a Bucks farmer, and if he were to go into the adjoining county of Bedfordshire he would see plenty of land so neglected, which is now clothed with a natural growth of couch Grass.

That much young permanent pasture is ruined through mismanagement is true enough we grant, but it is obvious that no just condemnation can be passed upon the work for such a reason. Repeatedly have we reminded our readers of the high importance of careful management of young seeds for the first two or three years, and no statement of cultural details is either complete or safe without such caution. Let us once more notice the indispensable points of the work. We require soil clean, fertile, and with deep fine tilth; pure seed of the best sorts of Grass and Clover at the rate of about 40 lbs. an acre. If sown now without a corn crop, the first growth will be ready for the lambs at weaning time, so that they only without the ewes may be folded upon the seeds. The folds are made small enough to ensure a sufficiently close consumption of the whole of the growth in twenty-four hours, a new fold being made every morning. Nourishing dry trough food is given in the folds, and thus all risk of any of the young growth running to seed is avoided, clean work is made of it, and a store of fertility is left behind which ensures a second growth of even greater vigour. The lambs are again folded upon it in a precisely similar manner in due course, but they are withdrawn altogether early in autumn. In the second year come folds for the entire breed-

ing flock, ewes and lambs going from the Rye Grass on to the seeds soon enough to avoid risk of seeding, and the process is repeated twice or thrice till autumn, but the pasture is again held in reserve through the second winter, to be used either for hay or grazing in the third year. All this involves some extra labour, but it is labour well bestowed, a means to an end which results fully justify. How far it may answer the general purpose to adopt it we hope to consider in another issue.

#### WORK ON THE HOME FARM.

Quick germination and so free a growth has following the sowing of spring come that most of the fields are already green with it, and the hoeing of winter corn is in full swing. Never did we have a more favourable season for sowing artificial manure upon winter corn, for frequent showers dissolved and washed it into the soil, so by that we may reasonably hope to see good effects from it early this year. We are trying our best to get more out of the land by putting more into it. We hear much talk about an average Wheat crop of four quarters an acre, but knowing as we do that all good land will yield nearly double that quantity under good cultivation, we cannot rest satisfied without doing all we can to obtain such desirable results. Perseverance in this must eventually be crowned with success; but we dare not hope for such a crop of corn this season, our farms are too large and too poor for it. We have the expensive and arduous task of restoring fertility to farms thrown upon the landlords' hands by tenants who having "farmed the land out," resigned their holdings upon the plea of failure through hard times. We may mention for the guidance of other agents in a similar position that upon appeal against income-tax upon such farms, we have obtained full remission under both schedules A and B upon proving no profits, fair attempts to let the farms, and that they were thrown upon the landlords' hands by tenants. In the preparation of our statements we are painfully impressed with the sad fact of the difference in value of all farm stock in a single year, even horses being no exception. They have fallen off so much in value that our rather large stock of home-bred colts are valuable for replacing old horses rather than for sale. We must of course continue breeding horses, but it will be only from aged mares.

We regret seeing sheep folded upon Rye before it is ready this year; scarcity of food is the cause; but Rye only 3 or 4 inches in height cannot keep the flock going long. We are fortunate in having a large park for the home flock, and the grass grows so fast now that we shall be able to give the Rye another fortnight before beginning folding upon it. Folding upon Turnip land is finished, and the land is ploughed and sown with spring Tares. Winter Tares are unusually backward, and we shall be fortunate indeed if they are ready for the sheep after the Rye Grass is done. We shall have to send the flock to an off-farm for this, and a clamp of Mangolds is being held in reserve there to be eaten on the Rye Grass. We regret to see so many farms with few, some with no sheep, at the present time. No doubt many a flock was sold for what it would bring last autumn, but we must deplore such rash measures, which practically mean living upon capital.

#### OUR LETTER BOX.

Small Handbooks for Farmers (*H. B.*).—Possibly "The Principles of Agriculture," by V. C. Buckmaster and J. J. Willis, published by Simpkin, Marshall & Co. at 1s. 6d., will suit you. More complete information will be found in the Handbook of the Farm Series, published by Bradbury, Agnew and Co. at 2s. 6d. each. Six of the series have been published. Probably the following four will suffice for your requirements: "The Equipment of the Farm," "The Crops of the Farm," "The Live Stock of the Farm," and "The Dairy of the Farm." They are written by well-known authorities on the respective subjects.

#### REMARKS.

4th.—Overcast, except a short time in morning; fresh breeze.  
5th.—Fair morning; sunshine about noon.  
6th.—Fine pleasant day; clear night; windy.  
7th.—Fine till 11 A.M., then dull and showery; wet afternoon and night, with gale.  
8th.—Fine early; heavy rain between 9 and 10 A.M., and between 4 and 6 P.M.; clear night.  
9th.—A mild day, bright sun, heavy soft hail showers from 10.40 A.M. till after noon.  
10th.—Bright early, dull and showery after.  
The third of a series of weeks getting gradually cooler, this one being of nearly the average temperature. Slight frost on two nights, and the ground white over with soft hail on the 9th.—G. J. SIMONS.

### THE PRIMULA CONFERENCE.

**E**XHIBITIONS of the stereotyped character have become so numerous in recent years that they are somewhat monotonous to exhibitors, the public, and all who are in any way connected with them. Specimen plants which were seen at one or two shows in a season are now found at a score, and beautiful though they be, they lose much of their interest after a few inspections. Something of novelty in exhibiting was required to awaken the public attention, and this the Council of the Royal Horticultural Society found in the conferences or congresses they initiated a few years since, and which have proved so successful. From an educational point of view these are far superior to ordinary exhibitions, and they constitute displays of scientific and practical value. Large collections of a particular kind of plant, fruit, or vegetable are obtained, representing a great number of varieties grown under different conditions and in widely separated districts, affording an admirable means of comparison and correcting nomenclature. The experiment has been tried with Apples, Pears, Daffodils, and Orchids in previous years, the present season being reserved for the Primulas, which thus constitutes the fifth of the series, and must be chronicled as an equal success.

The selection of the Primulas for a special gathering of this kind is easily justifiable; they are favourites with all for their unassuming beauty, and the family yields so many useful garden plants that it ranks high in horticultural importance. For example, *Cyclamen persicum* and *Primula sinensis* alone are grown in enormous numbers, and some market growers raise the former by tens of thousands to supply the widespread demand for such useful decorative plants. Amongst hardy plants the elegant American Cowslips (the *Dodecatheons*), the *Lysimachias*, including that cottage favourite "The Creeping Jenny," the brightly coloured Pimpernels and graceful Soldanellas, are examples of the Primrose family, but it is in the typical genus itself—the *Primula*, that we obtain the greatest number of forms and the greatest variety of colours. In the species delicate shades of yellow predominate, with purple, crimson, and rose tints, though in some that have been long under cultivation, and of which many varieties have been raised, combinations of all these and other hues are abundant. This is particularly the case with the *Auricula*, which for over 200 years has been carefully tended by innumerable admirers, who have multiplied its variations until it has been rendered one of the most changeable of cultivated plants. It seems that when once the stability of a plant's habit is thoroughly disturbed by hybridising this mutability becomes a character, and the variations can be increased at pleasure. In the Alpine *Auricula* this is well seen, for many have now discontinued naming the varieties, as from seed of a good strain numberless forms can be raised, a large proportion of which would at one time have been considered worthy of separate titles. The more highly bred, edged, or show

*Auriculas*, when judiciously crossed, produce similar results, but the proportion of sterling novelties is much smaller, and such experienced *Auricula* growers as the Rev. F. D. Horner and Mr. J. Douglas have had to discard many varieties before securing those which have been found worthy of special certificate honours at the hands of judges.

It is unnecessary for us to trace the progress of the *Auricula* to its present high standard and diversity, for Mr. Shirley Hibberd and the Rev. F. D. Horner give, in another part of this issue, the results of their researches and experience, and to these we refer all who are interested in the matter. There is, however, another portion of the subject that deserves a few remarks—namely, the *Primulas* which have come into general cultivation in addition to *P. Auricula*. A close companion to the *Auricula*, in the estimation of florists, is the *Polyanthus*, which may be botanically regarded as a near relative of our common Cowslip, *P. veris*. Varieties of this, with red and brown gold-edged blooms, have long been favourites, and as hardy garden plants the *Polyanthuses*, Alpine *Auriculas*, and the *Primroses* (descendants of *P. vulgaris*), take the lead in the genus. Amongst indoor *Primulas* that have attracted notice in recent years *P. cortusoides* and its varieties, with the stately *P. japonica*, are scarcely less popular than *P. sinensis*, though the still more recent *P. obconica* is likely to have a large share of public favour when its merits are more generally known. To the many lovely Himalayan and other exotic *Primulas* we need not refer, as in the articles which have appeared in our pages during the past six months the best have been fully described, together with the special treatment the plants require.

The combination of the National *Auricula* Society's Show with the *Primulas* afforded an extensive and varied display, the chief features of which are described in another column, two of the papers prepared for the Conference on Wednesday being also given. Owing, however, to the great pressure upon our space this week those by Mr. J. G. Baker and Dr. M. T. Masters are reluctantly held over to another issue. Mr. Baker's paper is entitled, "A Synopsis of the European Species of *Primula* with their Distribution," and he enumerates twenty species arranged in four groups—*Primulastra*, *Aleuritia*, *Auriculastra*, and *Arthritica*, which are distinguished by characters derived from the manner the leaves are folded, whether mealy or not, and some peculiarities of the calyx. Brief descriptions of the species are also given with their authorities. Dr. Masters' contribution is, "On the Root-structure and Mode of Growth of *Primulaceæ* in Relation to Cultivation."

There was a good attendance at the Conference, which was opened in the Crush Room at the Royal Albert Hall at noon on Wednesday by J. T. D. Llewelyn, Esq., and as proofs of the papers had been distributed, it was decided to take them as read, except Mr. Horner's contribution, which in his absence was read by a friend. This saved considerable time, as after a few introductory remarks by the Chairman they were enabled to proceed with the business of the meeting. Mr. Shirley Hibberd gave a brief but entertaining summary of his paper on the origin of the *Auricula*, which was followed by an exceedingly interesting discussion on the matter, several important facts being elicited. Mr. J. G. Baker spoke at some length in defence of the views he had adopted, that *P. Auricula* and the hybrid *P. pubescens* were the progenitors of the garden *Auriculas*, also giving references to plates earlier than those quoted by Mr. Hibberd, and especially noting the figures and descriptions by Clusius to prove that the principal European *Primulas* were defined, and that many variations of the *Auricula* type were cultivated before the close of the sixteenth century. Professor Foster and several others also took part in the discussion, but it was ultimately resolved that a suggestion by Mr. R. I. Lynch should be adopted—namely, to endeavour to obtain seed from the typical *P. Auricula*, to raise seedlings, and thus test its capacity for variation. Sir Joseph Hooker remarked that

he had listened to the discussion with much pleasure, and expressed high approval of the Conferences on special subjects, which afforded the botanists and horticulturists admirable opportunities of assisting each other. Dr. M. T. Masters and Mr. J. G. Baker each gave an outline of their respective papers, and after some further discussion the meeting was concluded with hearty votes of thanks to the Chairman and all who had contributed to the interest of the occasion.

## ORIGIN AND HISTORY OF THE FLORISTS' AURICULA.

By SHIRLEY HIBBERD. Prepared for the Primula Conference, April 21st, 1886.

In treating the origin and history of the florists' Auricula, in the interest of the Primula Congress, it is a matter of plain propriety to remark that I discoursed on the same subject in this place on the 25th of April, 1882, and the text of my thesis was published in the horticultural papers. With the present important task before me, I have again reviewed the history of the flower that takes highest floral rank amongst the Primulas, and shall endeavour to submit to your consideration matters that are possibly of importance, and that, I hope, will at least prove interesting. It will be convenient to dispose of established truths in the first instance, in order to obtain a proper basis for speculations on things unknown. The origin of the Auricula we will, for the present, assume to be unknown, but we have at command much of a trustworthy character in relation to its history during the past 300 years, and it will be a safe, even if a dull procedure, to rummage the books and set forth a few of the more promising facts and figures before tackling the portentous question of the origin of the flower.

### EARLY HISTORY.

A direct hint as to what to avoid as well as what to attempt may be derived from the reference to the Auricula in Beckmann's "History of Inventions." He quotes from Weismantel's "Das Blumisten" to the effect that Ovid, Pliny, and Columella knew the flower. Well, those writers were also acquainted with Garlic, Barley, and Figs; but we pay no attention to them until they offer some special information illustrative of the arts, customs, or necessities of the times in which they lived. It is somewhat to the purpose, perhaps, that Pluche, in "Spectacle de la Nature" (ii. 49), states that the Auricula was carried from Switzerland to Brussels by Walloon merchants. The second volume of this work was published in 1733, and it gives no clue to the date of the carrying. But the statement is of importance in connection with the general belief that the Auricula was cultivated in the Netherlands long before it was introduced into this country; and that the garden varieties of the flower were introduced by refugees from the low countries about the year 1570. We find mention of the flower in the works of Fuchs, Matthiola, Clusius, Turner, and Dodoens. But the sixteenth century botanists were but little better informed on the subject than the writers of the later Roman period; and it would be waste of time to attempt to formulate their scraps of information. Matthiola figures the true Auricula admirably at page 706 of "De Plantis Epitome" (1586). In the superb edition of Dodoens, printed at Antwerp by Plantin, it is very badly figured at page 148. By both it is described as *Auricula ursi*, and by this name of Bear's Ears it was generally known amongst the sixteenth-century botanists and gardeners.

In the year 1570 many artisans, driven from the Netherlands, settled in this country, and they brought their favourite flowers with them, including the best of their Auriculas. We begin business at the old shop, for Gerard, who published his "Herbal" in 1597, described and figured half a dozen varieties. On page 640 the contrast between the yellow and the purple Bear's Ears, although shown in drawings that are truly execrable, is full of instruction in respect of the question before us. The other figures are of little consequence, but the two that lead the way speak emphatically of the distinction between the true Auricula and the flower known to us as the Alpine Auricula. In plain truth they were as distinct then as they are now, and John Gerard's bad drawings hit the truth admirably. It is important also to note the remark of Johnson, in his edition of Gerard, published 1633, to the effect that there are divers varieties, differing in the leaves, which are green or hoary, and in the flowers, which are, white, yellow, red, and purple; the gardens of Mr. Tradescant and Mr. Tuggie being well furnished with such.

These things prepare us for what the immortal John Parkinson has to say. In his "Theater of Plants" (1640) he copies the bad figure from the Antwerp Dodoens, and describes twenty-six kinds of Auriculas. It is of the highest interest to note that amongst them occur a "stript purple," which he describes as singularly changeable; also a parti-coloured red and white "heard of but not seen." The Collic, that he describes as "somewhat sad but very lively," and the "Purplish Blew," appear both to have been of the class known to us as selfs, while "Heavens Blew," "Paler Blew," and "Bright Crimson," were of the class now known as Alpines. Of yellows he says there were many, but so mixed "I cannot expresse them." This is just what might be expected, and it may be fair to add that, as a matter of course, they were the least valued, because not far enough removed from the wild flower of the mountains, for the opinion appears to have prevailed that there was only one kind of wild Auricula.

In the "Paradisus" there are twenty varieties described, a few of which are admirably figured. Of these nine had green leaves without meal, and the remainder were more or less mealy. The flowers are presented as varying in colour, and some have a centre of the kind we call "paste," while others are without it. The colours are just such as we find in border Auriculas of the present day, comprising shades of red, purple, violet, marone, yellow, and white. We are certainly in the midst of Auriculas, not only of the mountain, but also of the garden. It appears that we have in the "Paradisus"—inexhaustible treasure as it is—the fountain of diversity as revealed to the penetrating eye of "Thine in what he may," the author of what he himself in his dedication designates "this speaking Garden."

This paper should be something like a catalogue of evidences, and I invite your attention to the description of "the great straw-coloured Beares eare," at page 238 of the book last mentioned. "This hath almost as mealy leaves as the last, but nothing so large; the flowers are of a faire

strawe colour, with a white circle at the bottom of them." These three last (that is the great yellow, greater yellow, and great straw) "haue no shew or shadow of any other colour in any part of the edge, as some others that follow haue."

The "blush Beares eare," the "Haire-coloured Beares eare," and the "yellow variable Beares eare," are described as edged flowers. For example, the "Blush" has a ground colour of a dark or dunne-yellow, shadowed ouer a little with a shew of light purple, which, therefore, we call a blush colour, the edges of the flower being tipped with a little deeper shew of that purple colour, the bottome of the flower abiding wholly yellow, without any circle, and is of very great beauty." The Hair-coloured is of a brownish yellow, edged with a shew or shadow of a light purple colour. The Yellow variable is of a fair yellow, "dasht about the edges onely with purple, being more yellow in the bottome of the flower than in any other part." I seem to hear our friends the florists say that these were flowers with shaded edges, of which we have many at the present day. Yes, the history of the flower is before us, and the "Paradisus" appears to provide us with the very first record of that kind of edging. Parkinson reserved a *bonne bouche* for a wind-up of his feast of Auriculas. It is the "Variable green Beares eare." This hath green leaves snipt about the edges; the flowers are yellowish green, having purple edges; these have no circles at all in them. This variable green with a purple edge might, for present purposes, be assigned the position of a pole star in the floral firmament; at all events, I, for one, feel attracted to it, and expect it to afford assistance in tracing out the order of the stars in the two constellations of Ursa major and Ursa minor that "in earth's firmament do shine;" for these stars seem to be now coming home to us.

### THE EDGED AURICULA.

There is no special interest for the present occasion in the progress of the Auricula in what appears to have been its early conditions as regards range of colour and variation of leafage. It is only when it assumes what, for convenience sake, may be termed its exhibition character, that it becomes more than ordinarily attractive, not only for the d-light of the eye, but as a subject for scientific study. Let us then consider the position of the edged flowers in the history. The one presented us by Parkinson is very different to the florists' Auricula of the present day; but it is probably a true Auricula, for the leaves "do turne and fold themselves a little backwards," the flowers are less expanded than some others, but alas! they have no circles in them, and the variety is not figured. This, we will say, is the most remarkable of all cultivated flowers, a small wonder, but a true one; a great achievement of art or a most extravagant freak of Nature. When did the first properly edged flowers appear? That question is now forced upon us, and is full of significance, even if judged by this first record of a green flower with a purple edge. A very trifling change would give us a purple flower with a green edge, and changes of that kind are common enough.

Strange to say, edged flowers were not received with open arms by the faculty. They had to win their way slowly to the favour of the florists, and on the principle that the world knows not its greatest men, the gardening world in general was for a long time ignorant of this unique production; this most precious of all the jewels in the diadem of Queen Flora. The proof of this will furnish matter for a paragraph.

In Miller's Dictionary, first published 1731, the edged flowers obtained no recognition, but Miller provided a good code of judging Auriculas, minus, of course, certain points that are of peculiar importance now. The fact proves that the flower had acquired extensive popularity, and inspired some kind of corporation that for present purposes may be designated the Auricula Fancy. Even in 1676, fifty years after Parkinson had so nearly witnessed the making of the florists' Auricula, John Rea, in his "Florilege," described striped flowers, and advised the selection of flowers "with white eyes that will not wash."

The subject obtains scientific treatment in Hill's "British Herbal" 1756, and the author, John Hill, M.D., boldly declares that many of the so-called species of authors "are no other than varieties of this plant rising from culture." At page 98 he speaks of the yellow Auricula as standing alone, and apart from those that produce red and purple flowers. Of these last he says there are three species not directly related to the yellow Auricula, and these he describes as narrow-leaved, round-leaved, and long-leaved. To one of the descriptions he adds the remark that "there is no judging by what one sees in gardens, where the accidents occasioning varieties are endless; but in those collected wild there is no error."

In Hill's "Eden," by the same John Hill, published 1757, Auriculas are fairly treated of, but edged flowers are not mentioned. Hanbury's "Body of Gardening," 1770, gives a hint in the way of our search in speaking of variegated Auriculas. It is a question of some importance whether the variegated flower of Hanbury was the striped flower of Parkinson, or a modification of that edged flower that had been noted as a curiosity 150 years before. There is clear evidence in the "Florist" of 1849 that in the year 1732 the edged flowers were not generally recognised; but in a code of rules for judging Auriculas, "flakes" and "stripes" are mentioned as important adornments of the flowers that were in favour in 1732. Mr. Slater, in his "Amateur Florists' Guide," gives a list of proper edged flowers that were in cultivation in 1776, and in my paper, read here in 1882, I assumed—I still think properly—that some of these were in existence in 1750, or earlier. The varieties known as Potts's Eclipse, Rule Arbitrator, and Hortaine were in cultivation in 1757. About 1785 the edged varieties were plentiful, and amongst them were Grime's Privateer, Popplewell's Conqueror, Gorton's Champion, and Wrigley's Northern Hero, which are still in cultivation, not as archaeological curiosities, but because they are good and have retained their initial vigour as cultivated plants for upwards of 100 years.

In fixing a date for the earliest record of an undoubted edged flower, I am indebted for valuable aid to my friend Mr. Harrison Weir, who, in a communication to the *Gardeners' Chronicle* of May 6th, 1882, refers to Sir Thomas Moore's "Flower Garden Displayed," published 1734. In this work many Auriculas are described, some of them introduced from Holland, and others raised in this country. It is important to note that the Dutch and the English varieties appear to differ as Alpines and true Auriculas, both classes finding favour here, but the English raisers having an especial affection for Auriculas proper, as apart from the Alpine section. Now, it is of the highest importance to observe that amongst many flowers of a class known as "Painted Ladies," because delicately improved, as ladies of that

day were, with a dusting of white powder, several are described as striped and one as distinctly edged. The edged flower is called Honour and Glory; it is said to have "a good white eye, and the flower striped with a dark reddish purple on a white ground, so as to leave the edge of the flower white." I repeat that this contribution to the history is important, because it not only places before us an undoubted edged flower, but it shows that the difference between stripes and edges was recognised. More than this, it shows that striped flowers were much valued, for one called the Royal Widow was sold for ten guineas, but the value of the edged flower is not suggested. It would be delightful could we find in the winning stands of the present season an example of the edged flower of 1731, which was very different to Parkinson's green with purple edge. As we cannot find the flower, we will look for Honour and Glory of a larger kind. Perhaps in the soundness of our work, and the sweetness of our temper, and the earnestness of our hopes, we may be promoting a higher and wider appreciation of the Auricula, in which case honour and glory are secured, and we may safely proceed in the good old way, according to the sacred precept, "Whatsoever thy hand findeth to do, do it with all thy might."

#### ORIGIN OF THE AURICULA.

Let us now ask the question, Whence came the florists' Auricula? Charles Darwin, in "Forms of Flowers," page 43, derives it from *Primula pubescens*, which is represented as a hybrid between *P. Auricula* and *P. hirsuta*. Herbert, in "Horticultural Transactions," vol. iv., page 19, considers *P. Auricula*, *P. helvetica*, *P. nivalis*, and *P. viscosa* to have been concerned in the parentage. Indeed, Mr. Herbert considered he had raised a powdered Auricula from *P. nivalis*, which may be regarded as a white-flowered variety of *villosa* of Jacquin. As he gives no description, it is impossible to say whether his plant would pass for an Auricula if brought up for judgment here to-day; but he was not the kind of man to make any glaring mistake, and his plant must have differed from *nivalis* to entitle it to such special mention. Mr. Herbert, at the same reference, suggested that *P. Auricula*, *P. helvetica*, *P. nivalis*, and *P. viscosa* are but varieties of one and the same species. To the list may be added *hirsuta*, *pubescens*, *minima*, and *nivea*, for in truth we are now trading in names, and we shall have to be careful that we do not mistake shadows for substances. In his "Die Geschichte der Aurikel," Professor Kerner avows his belief that *Primula Auricula* is not subject to variations, and that it probably did not keep a place in gardens for any length of time beyond the middle of the seventeenth century. But then he obtains for the making of the garden flower the blood of *P. Auricula* and *P. hirsuta*, which he regards as the parents of *P. pubescens*; and from this last, a reputed hybrid, he derives both the edged and the Alpine varieties. This proposal will not be accepted by many of the raisers of seedlings, whose experiences have rendered them familiar with the peculiarities of both classes. It affords but poor promise of an explanation of the yellow colour and the farinose decoration of the Show flowers, nor does it satisfactorily explain the shaded margin and the persistently naked leaf of the Alpine section. As regards the yellow of the Show flower, it does not appear in its true proportions to the casual eye; but if you will carefully wash away the paste you will find that it is laid upon a yellow ground. It seems to be the function of paste to play a game of deception. Kerner's views have been partially approved by Mr. J. G. Baker, of Kew; but he appears to lean to *Primula Balbisi* as a prominent progenitor, and he associates the edged flowers and the Alpines as at least not specifically distinct. The Rev. F. D. Horner, who combines experience as a raiser with knowledge of species and a fine faculty of observation, reckons *Primula farinosa*, *P. scotica*, *P. marginata*, *P. intermedia*, and *P. viscosa* as concerned in the parentage; and probably he would separate the edged flowers from the Alpines as of different origin.

Finally, I propose to you that we may with advantage regard the edged or Show Auricula and the Alpine Auricula as, for present purposes, specifically distinct. The general agreement of the Alpines is with *P. commutata* and *P. pedemontana*, the last-named being emphatically reflected in it. On the other hand, *P. ciliata* of Moretti may be associated with *P. Auricula* as concerned in the formation of the florists' flower.

But, after all, this is like arguing in a circle. The two that I have selected as begetters of each group are specifically one or two at the discretion of the botanists, as they may take broad or narrow views. We are in the same plight as regards the *Primulas* as we were in regard to the *Daffodils* before the Congress operated, when, as you will remember, a great reduction of the species was carried into effect. I will venture now to say that the employment of names in the expression of our ideas as to the origin of the Auricula must be subject to the possible reduction of names by the Revising Committee. I can find a dozen or more so-called species that are possible parents of the Auricula, but as I question their specific independence I do not feel that making a catalogue is, in this case, the solution of a problem in biology. As for *Palinuri*, I cut short the connection by dismissing it as a possible progenitor of Auriculas.

#### CHARACTER OF THE AURICULA.

Let us now make a brief study of an Auricula with reference to the facts that are before us. In certain characters it is constant. The leaves are stout in texture, often leathery, sometimes slightly cartilaginous. The flowers are always in a many-flowered visible umbel, never, like those of the *Primrose*, appearing singly from a concealed umbel. The floral bracts are short, never, like those of *P. calycina*, longer than the flower stalks. The corolla is distinctly contracted below into a tube and expanded above into a salver; it is never contracted into a cup or goblet, as in *P. sikkimensis*. The dusting with protective meal is not a distinguishing feature; but its abundant appearance as a decorative character of the exhibition flower is strikingly characteristic, and though it may be said that by long-continued crossing and selecting its appearance there may be regarded as the work of the artist called Man, yet his work is limited, not only by the capabilities but by the disposition of Nature. The powder belongs to the face of the flower, although its quantity and arrangement may be an exaggeration of Nature's intentions. The show of yellow in the colouring of the flower is a constant character. This is a colour wanting in many of the supposed parents. It should be borne in mind that the flowers of highest quality represent long-continued and severe selection; and therefore in an exhibition, or even in the general

stock of the cultivator, we do not see the entire character and possibilities of the flower. The seed-bed offers the raiser many that he will simply destroy, because of their nonconformity to rules, and amongst the condemned will be many of the so-called fancy flowers, that have no body colour, and approximate to the species. It should be remembered, too, that all the edged flowers have green edges; for although classed as green, grey, and white, it is only the relative density of the meal that makes the difference. It has been boldly declared that this green colour is a monstrosity indicative of a return of the flower to the status of a leaf, but we will defer the serious consideration of that proposal until we see the flower take the form of the leaf in addition to a touch of colour, which, from the florists' point of view, is one of its distinguishing beauties. It would be more reasonable, perhaps, to regard the green colour as a remainder of the original colour of the flower, for, according to the doctrine that has found general acceptance, the flower should be first green and then yellow, with the potentiality of changing to red and ultimately to blue.

Considering Professor Kerner's proposal in connection with these facts, it may not be irreverent to say that it leads us nowhere. We are to derive two groups of plants that differ by larger degrees than many that are recognised as distinct species, from a parent plant that is a reputed hybrid, and that possesses only a few of the characters required. We are assured that the purple and marone colours that are so prominent in the edged Auriculas cannot be derived from a species known as affording only shades of yellow. Those who make the declaration evidently forget the wide range of colouring of the common *Primrose*, wherein we have almost every colour except true blue. Linnaeus grouped *Primroses*, *Oxlips*, and *Polyanthuses* as forms of one species; and that view, though for long repudiated, is now generally accepted, and the point is especially insisted on by Bentham in his "Handbook of the British Flora." Between yellow and blue there may be somewhat of a gulf fixed, especially in the variations of a species; but from yellow to shades of red and purple is a transition far from uncommon. We have examples not only in the *Primrose*, but also in the *Chrysanthemum*, *Hyacinth*, *Tulip*, *Pansy*, *Carnation*, *Hollyhock*, and *Antirrhinum*. If you wander about in search of a source of the red and purple tones in Show Auriculas, you will never find means to account for the brilliant violet blue body colour of the variety known as Colonel Champneys, while others may be found that are apparently equally far removed from the possibilities of the botanical colourist. The truth appears to be that the colours we cannot by direct descent account for are in reality self-evolved, and belong to the category of changes that accompany and follow cultivation. In other words, these colours, with other characters that might, with equal reason, perplex us, are, in a certain sense, laid on by the hand of the cultivator. It is the fear of the botanist, who cannot recognise any merit in his brother the florist, that prompts him to find in this or that flower that the hand of man has left untouched, the sources of properties that the florist has developed by long-continued cultivation in view of an ideal model, towards the realisation of which he is ever striving, but never attaining, though happy in the endeavour, and justly though quietly proud of what so far has been actually accomplished. To obtain the two great classes of Auriculas from *Primula pubescens* is a greater extravagance on the part of Professor Kerner than any florist has ventured on as yet; but the florists have discovered long since that seeds derived from show flowers do not produce Alpine varieties; and, on the other hand, it is all in vain to hope for edged varieties from the seeds of the Alpine section. The general acceptance by the botanists of the proposal of Professor Kerner shows how much they need in their researches the aid of men who have acquired experience in the raising of new varieties of garden flowers, and in the management of garden plants generally.

Parkinson, 250 years ago, had a green flower with a purple edge. That must have been in existence long anterior to the writing of the "Paradiseus." It is not extravagant to entertain the supposition that it had been in existence hundreds or thousands of years before. In the same collection were striped flowers, and these appear to have increased until in the early part of the eighteenth century they abounded. Then, again, we hear of an edged flower called Honour and Glory in the year 1732, when Sir Thomas Moore described it. Since then the edged flowers have increased in number, and now constitute a race that has all the useful characteristics of a species. The green has proceeded outwards to the margin and settled there; the stripes have moved in the same direction and formed a ring within the margin; and the farina has accumulated around the centre to form what is termed the paste; while a rich tone of yellow marks the centre, and gives accent to the green of the primal flower, the result being an arrangement of colours in four orderly masses, three of them in circles of definite geometrical proportions. The *Carnation* offers a nearly parallel example, for here we see the flakes of the flower moving outward to the edge to fashion the *Picotee*. It is like the action of centrifugal force, the colours appearing desirous of moving off into space. What is termed the thrum does not appear to demand special notice in connection with the origin of the flower, but I shall not seriously interrupt the study of the subject by remarking that Charles Darwin found the short-styled flowers the most productive of seed, and thus the taste of the florist in this respect is in strict accord with the frugal notions of Nature. The rich yellow of the thrum is another feature favourable to the flower, which is as hardy and vigorous as any of its kindred, although commonly represented by the traducers of the florists as a debilitated thing; that requires a man and a boy to hold it up.

The Auriculas naturally divide into two groups, the Alpines leaning to *Primula villosa*, the Auriculas to *Primula Auricula*. There does not appear to be any necessity for the admixture of *Primulas* that has been hypothesized for the formation of these flowers. The facts of history suggest that in all their more distinctive forms these two sections represent only two species, and that each in its essential characters is self-contained and self-containing. We have no proof at any time of distinct hybridity, but it must be acknowledged as a fact favouring the view of a considerable range of parentage that the allied species breed freely together. The *Primulas* that most often come into contact with man are, like him, of a sportive nature. The laced *Polyanthus* might perplex us with its golden edge, and there are many edged *Oxlips* in the present Exhibition, and some that display stripes and incipient edgings, and that are probably in a condition of change corresponding with the Auriculas of Gerard and Parkinson.

## IMPROVEMENT OF THE GENUS PRIMULA.

[A paper by the Rev. Francis D. Horner, Lowfields, Burton-in-Lonsdale, read at the Primula Conference, April 21st.]

I ONLY take up this question at the direct request of my brother florist, Mr. Samuel Barlow, of Stakehill. The subject could not have been in better hands than his, nor associated with a name more known and honoured among florists. There is, however, this one thing to temper my regret, that I must take his place, and to add value to my paper, that the question I am to introduce is a very old and interesting one between Mr. Barlow and myself. Through all the years of our intimate friendship have we stood together over the Auricula in bloom, and taken careful thought as to the yet richer development of this highly cultured flower, a favourite with us both from boyhood.

Mr. Shirley Hibberd in his introductory paper, historical and descriptive, will have given some definite idea of what the florist's Auricula is; so that I shall not here be using technical terms altogether strange to those not conversant with the properties of the flower, some of which had not been acquired in the dawn of its culture some 300 years ago, nor are even dimly visible in the simplicity of its supposed wild ancestry. If any of the points for improvement should seem minute—perhaps fanciful—I can only say that the highest qualities have, as a rule, been gained only by such gentle gradients and slight curves as these. It is often some delicate touch, small in itself, but great in its effect, that raises a flower at once above the inferior or commonplace. To the accustomed eye the Auricula has an intense individuality, and very slight variations of feature alter an expression and enhance or detract from a type of beauty.

In a breadth of its brilliant bloom there is the effect as of many eyes turned steadfastly upon their admirers; and there are faces in the flowery crowd on which one may read many expressions of a life and character super-floral. Like as in a bed of Pansies there are many comical casts of countenance, expressive of astonishment, anxious inquiry, perplexity, and brown study; so here, in an exhibition of the Auricula, as representative of its beauty as can possibly be made, the flowers look all gentleness, candour, honesty, simplicity, and refinement.

Glaring faults that impart a low and evil look are all absent here; and hence I am not able to submit to you how impudent and barefaced is the "pin-eyed" flower, wherein the stigma, protruding from the hollow throat, is like a tongue thrust out. Neither, how loose and vacant is the expression of the inordinately large tube; and how cunning and cold that of one too small. Nor how lack of breadth in the eye or "paste" of the flower is like that in other eyes which cannot look you in the face; and how narrow ground colours betoken indecision and want of thoroughness. "Edges" have their own expressions, too; something like meanness when too narrow, and akin to bounce in over-breadth; for excess of edge is often concurrent with excess of size, and coarseness, almost inseparable from immensity in the Auricula, is one of its gravest faults.

Had it been practicable, a representative collection of failures in desired qualities would have formed a very clear illustration of mistakes. Yet I would not say it would be convincing; for invariably the uninitiated friend who comes to tell you which of all you have he likes the best, settles his admiration upon something that has set at naught all proper principles, and he does violence to your feelings by approving of it. But the greatest ordeal of praise I ever had was the remark, transparently innocent, of an old country parishoner, "They almost come up to artificials, sir!"

The question in what direction efforts should be made for improving the florist's flowers of the genus *Primula* resolves itself, descriptively, into the statement of the shortcomings more or less prominent and obstinate; prospectively, into what the possibilities are of which hopeful shadows in faint shape are cast before; and practically, in what system of experiments we should seek to overcome the faults, and win into reality the promise of fresh beauties that a flower, inexhaustible in its powers of variation, naturally affords us.

As an experimentalist I will adhere to the practical: use bare description as little as I may, and bring young hopes downstairs from the nursery realms of imagination as considerably as I can.

## PROPERTIES.

**Form.**—The first property to be worked for in the Auricula is, I submit, the perfection of that form upon which the colour-attributes of the flower will be the most effectively displayed. Colour can always be worked up to, and the florist may tarry patiently for this until he has the form of grace whereon to call it into play. I always choose as the maternal parent of Auricula seed the best flowers I have in breadth, circularity, flatness, substance, and smoothness of petal; while for male parentage I do not depart further than must be from form. Petals cannot be too broad, so long as they will expand equally and kindly. If they do not meet through narrowness or roughness the beautiful design of the colour zones is interrupted by vacant spaces signifying nothing.

The edged classes and the selfs have each their own type of error in respect of form. In the "edges" it is generally a pointedness of petal; in the selfs a central notch or heart-shaped depression. In the edged flowers the fault has long been noticed and regretted, and has now been brilliantly overcome, especially from the appearing of Lancashire's Lancashire Hero in 1846 onwards; but among the selfs until recent times there was hardly an exception to the rule of notch. The indented petal of the self seemed silently allowed to pass as the typical petal of the class.

**Selfs.**—For improvement of the self Auricula, my experience convinces me that the best results are to be obtained through entirely self parentage. I would not say that a correct self flower has never come from edged parents, for Mr. Campbell believed that his brown self Pizarro, the best flower in the class at the time, was raised from a green-edged parent, and Mr. Simonite that a good blue self of his was obtained from a white-edged seedling.

Certainly, however, my own best selfs have sprung from purely self parents, and latterly from a self descent comparatively ancestral. Selfs have generally a shorter duration of bloom than the edged flowers, which possess greater stoutness of petal, and in which the green, whether pure or mealed, is a colour of greater and more leaf-like vitality.

It might be theoretical to suppose that if selfs were crossed with these a

greater substance of petal would be transmitted. In practice, however, it is found that all seed from purely edged parents produces a majority of self varieties, and vast numbers of these are notched, and frilled, and flimsy flowers. I have never had wilder flights of seedling selfs than from that grand grey-edge, George Lightbody. It would almost seem that an "edge" did not know what a good self ought to be.

I think that for selfs we should work patiently among themselves, advancing in substance as we certainly are by sure if slow degrees, and not weakening the newly acquired and most supreme point of the "rose-leaved" or perfectly rounded petal.

Another point to aim at in the development of the self is the addition of some that would be constitutionally later in blooming than most of those we have. Campbell's Duke of Argyll (rich crimson, but deeply notched) might transmit this habit, and be over-ruled in this fault.

The Auricula bloom in a collection loses much of its power and beauty when the quiet yet emphatic selfs are gone. It is like the beginning of the end, as when in the fading summer the swallows take their flight.

**Edged Flowers.**—With reference to improvement in form in the green, grey, and white edges, I would remark that in these, good form, beyond its intrinsic value, has an influence inductive of other good properties. Rounded petals are associated with roundness of the white-mealed circle termed the "paste," while with the pointed petal the paste is often, as by a kind of sympathy, drawn into corresponding irregularities; which only intensify the serious fault of an angular appearance.

For form's sake, naturally, such flowers as have the roundest, broadest petals will be selected; and such a variety as George Lightbody, among those well known and distributed at present, will serve as a type.

If good form in both parents should justify it, my conclusions are that edged flowers should be crossed with their class fellows; for one line of improvement in the Auricula certainly lies in doing all we can to intensify and magnify the class distinctions, gaining green edges as deeply green as possible, and white edges as densely mealed. The "undecided edge," too green for grey, and too grey for a pure green, is not desirable. Still the Auricula is so very sportive that some decisive edges will be obtained from parents dissimilar in class; and the experiment is justified, of course, if there be no alternative, and if some marked improvement in form may be hoped for from it.

**Petals.**—Connected with form, in addition to the roundness and level disposition of the petals, may be mentioned their number. This is variable, even in different flowers on the same plant. Five is probably the normal number, for beyond this the Auricula will take a playful liberty with the proprieties of its Linnæan order, Pentandria, always producing just as many stamens as there may be petals; and if one be of inordinate breadth it is accounted as two, and decorated accordingly with two stamens. This may be a botanical misdemeanour, but is not an offence under florist bye-laws. The same is noticeable also in the florist Tulip, which is required to have petals neither less nor more than six, but is occasionally misformed with four or five, and seven or eight, when there is always one attendant anther for each. In the Auricula five or six petals are sufficient for a broad round flower, and more than eight begin to look narrow and laboured.

**Colour.**—When we turn from improvement in form to views of improvement in colours, both in richness and variety, a very wide field of development lies before the florist. Possibilities peep out but half concealed or only in the rough, revealing themselves in the rarer combinations of colours that a few seedlings crudely show; and these beckonings need but to be followed to obtain in time some new and beautiful combinations.

The Auricula is a most richly endowed flower, possessing already, singly or combined, all colours of the rainbow—violet, indigo, blue, green, yellow, orange, and red; and further still and rarer, that negation of all colours, black. In edges we do not look for a gift of other than the green, grey, and white, now so well known and fixed, while the colours of the paste and tube are constant and common to all. There remains but one more colour zone upon the flower, to give variety and play, and that is the ring or belt of velvety surface known as the "ground" or "body" colour.

Disposed between the green or powdered edge and the white mealed "paste," it is a solid band along its inner edge; while on the outer it flashes in lively pencillings, bold and blunt in some varieties, sharp and delicate in others, towards, but not dashing through to the petal edge. It is this lively characteristic of the body colour that entirely takes away any tameness or monotony, hardness or fixity that a series of strict concentric circles might be supposed to have. The body colour should most certainly have a good solid foundation before it begins to feather off, because a few slight pencillings only have a very feeble and scratchy effect, while a bold and rugged style of its outer edges is massive and handsome in the extreme. But by an expressionless ring of black, dreary as a black hatband round a white hat, I would not advocate taming the Auricula down to the miniature similitude of an archery target. Such a picture of utter and unbending primness (for which the botanical equivalent is not *Primula*), as a series of severe circles may indeed have been in old time perpetrated in hard diagram; but this was only as the bare skeleton which Nature in real life shall clothe with all fulness, softness, and grace and vivacity.

The body colour is the "iris" of the flower's eye, and black is at present the most settled colour. A good black is very safe and true, lasting well upon the flower, a most important point; and hence it has been a favourite colour, especially with florists in the north, and the more encouraged, pursued, and developed. Indeed other body colours were regarded with marked disfavour by old Lancashire florists, though if other colours had been worked up to the truth and steadfastness of the black, there is nothing but local fancy or prejudice to make them less valuable and less beautiful. Little encouraged in such variety, the Auricula has shown a capability, if only initial yet, of giving both blue and crimson as the ground colour in edged flowers. These will of course require cultivating up to intensity and steadiness, and I submit this as a very interesting new path of improvement.

One marked difficulty so far has been that of transmitting to any flower, whether self or edged, the all-important feature of a rich gold tube, if that flower has tints of violet or blue. Their tubes are pale or greenish-yellow, always a colour of low vitality and weak endurance. Some seedling blue selfs, however, by pollen from gold-tubed varieties, are better in this respect than the old blues.

Memories come back to me here of some old flowers that might have been helpful towards new combinations of colours that are faint and timid, and wavering yet.

Such were Moore's Violet a green-edged flower, with violet body colour, and a green edge of Traill's (Rev. George Jeans), in which the ground colour was of a lilac tint. In white edges were Aston's Bonny Lass, with beautiful violet, and Maria, richer in colour. These, however, and others of like colour, all were weakened by a pale and watery tube; and further, the ground colour was not of one uniform steadfast shade, which it decidedly ought to be in both edged and self Auriculas. Red or crimson as a ground colour of edged flowers has not yet been obtained of any intensity. Lightbody's Fairy Queen and Star of Bethlehem, and also Smith's Waterloo, were green edges, in which the body tints were a shade of red-plum, and a white edge of McDonald's was lighted up with a brighter red. Chocolate-brown is another possible change in ground colours worthy of being followed up. It occurred in Lightbody's white edge Countess of Dunmore, and in Smith's Ne Plus Ultra. These red and brown ground colours are happily not associated with the weak tube colours of the blues.

Mr. Simonite, in his Heather Bell and Aurora, has better blue-grounded white edges than the old ones, and the tubes, though not of a strong yellow, have more stability. An offer of a red-grounded green edge occurs in a rather erratic seedling of Mr. Rolt's. The edge is pure but insignificant, and the red ground colour brightens with age, but is too broad, and runs wildly out at the petal edges. Such a flower would be worth crossing with some green-edge seedling of fine form, in which existed the fault of a ground colour much too slight and narrow.

In new types of colour in self the last great acquisition came through Mr. Campbell's success in his efforts to produce a true crimson self. Some fifteen years ago he sent out, as the result of many years' work abounding in failures, two intensely crimson flowers—the one better than the other both in its colour and its rich gold tube, but both of them notched in petal. These flowers have transmitted their colour well to seedlings of better petal.

Within the last two or three years another new and very beautiful break in self colours has occurred among both Mr. Simonite's seedlings and my own, showing yet another direction in which we may seek to enrich and improve the Auricula. This new colour is a very lovely and decided pink. The flowers have happily been nearly always gold-tubed, and the petal is a fully rounded type. This young colour, however, is not easy as yet to obtain solid—i.e., unshaded and steadfast. Some have failed by growing slightly paler with age, or in losing with age the surface of the petal; so that what is velvet at first, is calico at last.

There is no doubt, however, that the true pink self is a coming flower, and I name it as one illustration more of the direction in which the Auricula may be improved.

I have spoken of the failures of this newly-won colour—the successes must speak for themselves when they can.

*Adolescence.*—There is something very curious in the blooming character of the first three years' life of an upgrown seedling which it is important to mark and allow for, because it certainly is connected with the practical part of our question.

It is not an invariable rule, but it is a frequent occurrence for a seedling that blooms with brilliant properties in its maiden year to flower the second year in much inferior if not loose character. This is oftener the case with the complex-edged flowers than with the simpler selfs. At the third year the flower may either return to its early promise, or go again astray. I do not know how to account for it, but it is a noticeable feature in a long experience.

It would seem as though the plant were affected by some unseen change or turning point in passing from its seedlinghood to becoming an established variety. Certainly some seedlings that show brilliant properties the first year never afterwards display them; and occasionally others, that one has gladly given away to friends with garden borders, have, like the "ugly duckling" of the story, developed into very swans of excellence.

I mention this, not only that joy over some sudden acquisition may be tempered with gravity, but also that doubt may be not unlighted with hope.

I do not cease to feel some anxiety for a brilliant seedling, and some hope over a rather disappointing one, till I have seen them at their third bloom. Some faults are decisive, such as the pine-eye, the pale tube, the angular paste, the notched or pointed petal. Of such there is no hope. But if properties of tube and paste and petal are fine, I do not discard the seedling because, at its maiden bloom, the proportions and other qualities of the ground-colour and edge may not be correct. There may be a good flower in disguise.

#### ALPINE AURICULAS.

I pass on now to a brief notice of that other division of the Auricula as a florist flower, which is technically known as the Alpine. These very beautiful flowers possess, as features of distinction from the edged classes and selfs, a perfectly unmealed centre or eye, and petals richly shaded from the deepest to the lightest tints of that one colour which the flower has adopted. That shading cannot be in tints too numerous or too softly blended.

The tube of the Alpine so closely follows in colour the centre of the flower that it should have an expression in form all the more marked, because there is the less power of contrast with the centre by colour. It is a great point of beauty in all Auriculas that the mouth of the tube should be well defined, and rise fully to the level of the flower's face, otherwise there is the appearance of a weak and sunken eye.

The Alpine Auricula is divided into two sections, distinguished by the golden, and the paler, almost primrose-coloured centre. The golden centre is the higher type. In the Alpine, as in the edged flowers, it is again the flowers possessing violet or bluish colours that exhibit the palest yellows in the tube and eye. Flowers would no doubt be very highly valued in this class of violet shades if they could be obtained with the rich golden eye of those with crimson.

#### THE POLYANTHUS.

I must not close this paper without including the florist Polyanthus, a lovely sister of the Auricula, and in sore need of reinforcement in sterling

varieties. Some of the very best Polyanthuses, like Kingfisher in the red ground flowers, are lost to cultivation; and among black grounds of high merit, Lord Lincoln seems all but gone. Many gardens strains of Polyanthus are termed "gold laced," but they are a far remove from the florist flower with its cultured properties. The resemblance in most of them looks nearest when seen at the greatest distance. The decision, purity, and refinement of our Polyanthus are not in them.

Mr. Barlow's success in raising both black and red ground flowers of very high character, perhaps in red more especially, is a proof that though the flower may not be more ready than its radiant sister, the Auricula, to give the properties we would have, still it will repay all good care bestowed in judicious crossing.

I do not think that any foreign blood of strains outside the florist pale, however proudly spoken of, should be introduced under the plea of giving vigour, which the standard old sorts have, alas! too often lived to lack. From such extraneous source of robustness will come much unruliness. A more safe return to soundness of constitution will be naturally obtained through seedlings, because seedlings naturally possess it, and happily young blue blood is no exception to the rule.

For suggestions of improvement in the Polyanthus I can but briefly state the properties that require to be exemplified in as many living representations of their beauty as we can obtain. The two brilliant extremes of class colour will be a black ground, or a scarlet ground within the lacing of bright yellow. Whatever the body colour be, it must consist of one rich uniform shade; and the yellow, which is best when a clear lemon-gold, must be free at the eye or centre from any other shade of yellow. The gold of the lacing must exactly match that of the eye, and the lacing itself must be of exquisitely smooth edge and even width. It must both completely edge the petal and strike down through the centre of it to meet the golden eye. The central line of lacing is frequently broader down the middle of the petal than round the edge, but the nearer it is of the same width the better.

It is characteristic of the Polyanthus petal to be deeply notched in the centre, so that the circular edge of the Auricula petal is not looked for here.

The centre or eye of the Polyanthus should occupy a wide circular space upon the flower. It can hardly be too wide, and is often not wide and circular enough.

The mouth of the tube should be extremely well defined, and even most slightly raised above the level of the centre. As in the Auricula, the tube should be filled with bold anthers up to the surface, with the stigma almost sessile below; and all flowers should expand equally and well.

These are the points to be attained and strengthened in the improvement of the florist Polyanthus; and it will readily be seen how far these lines of beauty, which give such brilliance, purity, and refinement, lie beyond the comprehension of the common garden border strains, and how far too few are the beautiful florist Polyanthuses we have that fulfil this standard.

## THE PRIMULA EXHIBITION AND CONFERENCE.

APRIL 20TH AND 21ST.

The weather continued unfavourable so late in the season that the most hopeful of those who had interested themselves in the proposed Primula Conference began to entertain grave doubts if they would obtain a sufficient number of entries to make a good representative show. Until quite recently this uncertainty was not removed, and the display provided on Tuesday was a surprise to many of those present. Never have so many species and varieties of the genus *Primula* been shown together before, and the numerous admirers of these plants had an opportunity of studying their favourites in all their varied forms. We have grown accustomed to the displays of richly coloured and costly Orchids, showy Pelargoniums, Begonias, and other plants, but it was quite a relief to turn to these simple yet beautiful flowers, so fresh, pleasing, and unobtrusive. Regarded merely from an effective point of view it would not be considered as sufficiently bright by those who admire the gaudy tints of the plants above mentioned, but there were scores of pretty plants, not large enough to make a great display individually or collectively, yet extremely interesting. There was a good proportion of really useful garden plants, chiefly varieties of the *P. vulgaris* type, with brightly tinted flowers, the charming *P. rosea*, and the pure white *P. nivalis*, while there were also large numbers of species, perhaps nearly one-half, that would never become popular plants though well worth including in collections.

It would be unnecessary to enumerate in this report all the species and varieties shown, and in the following notes it has only been attempted to point out the most distinct, handsome, or remarkable. A full detailed report will probably result from the labours of the Conference, and in this we may expect to see many of the errors corrected which are now only too obvious in the nomenclature. There has been much confusion amongst the Primulas, and one highly important practical result from this gathering will be that some hundreds of plants will be returned to their homes under correct names.

The Primula exhibits occupied a table the whole length of the conservatory on one side, a table nearly half the length on the other side being similarly devoted to Primulas and hardy flowers, Messrs. Paul and Sons' Roses, Barr and Sons' Daffodils, and the National Auricula Society's exhibition filling the remainder of the available space, and together constituted both a large and handsome display.

Of the Primula groups the following were the most important:—J. T. D. Llewellyn, Esq., Penllergare, Swansea, had a collection of well-grown plants, the most conspicuous being varieties of *P. Sieboldi* with *P. japonica*, *P. verticillata*, *P. cashmeriana*, the old double crimson Primrose, *P. obconica*, very fine, *P. intermedia*, and *P. viscosa* varieties, together with the typical *P. Auricula*, which was collected by the exhibitor on the Pyrenees. G. F. Wilson, Esq., Weybridge, had an interesting series of violet-crimson Primroses, seedlings from Scott-Wilson, and including the beautiful variety Alice Wilson, which was certificated last week. Some exceedingly fine spikes of *P. denticulata* were shown from the open

border, and Mr. Wilson says it grows as freely in his garden as the common Primrose. From the Royal Gardens, Kew, was contributed the largest collection in the Exhibition, comprising plants of 118 species and varieties, though necessarily these included many that were not in flower, as it would be impossible to obtain so many forms in their best condition at one time. Some of the most notable were *P. cortusoides*, *P. vulgaris*, *P. Sieboldi*, *P. viscosa* varieties, *P. denticulata* cashmeriana, *obconica*, *Obriati*, *involucrata*, and *spectabilis* Wulfenianiana. Forty-eight coloured plates of Primulas were also shown with this group. A smaller but very good collection was sent from the Royal Botanic Gardens, Edinburgh, the most remarkable plant, and indeed one of the finest in the conservatory being *P. obconica*, which had thirteen handsome trusses of large flowers. This plant was greatly admired, and afforded ample proof of what good culture can effect with this useful Primula. With these were several *Androsaces*, the one named *rotundifolia macrocalyx* having a very uncommon appearance, each pale pink flower having four large spreading calyx lobes beneath it, something like the curious old Polyanthus with large green calyxes.

Dr. Robert Hogg exhibited plants of the common English Oxlip and the true Bardfield Oxlip, together with a seedling that had been obtained from the latter, having pale purplish flowers, very pretty; and two seedlings from this had still more strongly marked characters, the flowers being tinged with red. It was an interesting series, showing the gradual changes effected, although it has been thought that the Bardfield Oxlip does not produce seed. Messrs. J. Backhouse & Son, York, had a large collection, comprising a number of varieties of *P. vulgaris*, *P. marginata*, and *P. denticulata*, with the bright yellow dwarf *P. floribunda* and innumerable others, *P. ciliata* purpurea, with rich crimson purple flowers, being one of the most effective. Several choice hardy plants were included, a bright purple variety of *Polygala Chamæbuxus*, a handsome *Darlingtonia californica*, and the pretty *Daphne Blagayana*. Messrs. J. Veitch, Chelsea, showed a group of Primroses very bright and varied in colours, the single white and double yellow and lilac forms of *P. vulgaris* being extremely good. With them was *P. obconica*, one of the Veitchian introductions, *intermedia*, *involucrata* farinosa, and the most diminutive Primula in the Exhibition, *P. mistassinica*. This had leaves about half an inch long, flower stalks an inch high, bearing one or two star-like white or pale blush flowers. It is a North American plant and was one of the curiosities of the Show, contrasting strangely with a gigantic form of Auricula in Mr. Dean's group. A so-called "hybrid Primula" was shown by Mr. T. Walkden, Marsland Road, Sale, which was said to have originated in the following manner. Some plants of *P. nivalis* were grown in a frame with ordinary Auriculas, with the object of procuring a cross if possible, though this was not attempted artificially. Seed was obtained, and from this the plant shown and two or three others were raised. It had large white flowers and a pale yellow eye, a stout truss, and green notched leaves, the general habit being similar to the Auriculas. Mr. R. Dean, Ealing, showed a series of Primroses, such varieties as Cloth of Gold, Crimson Beauty, and Scarlet Gem being very noticeable for their brightness of colour, the hose-in-hose Jackanapes and several unnamed seedlings being similarly good. The giant of the Show has already been mentioned: it was in the form of the double Alpine, with flowers 2½ inches in diameter and partly double, some of the stamens being petaloid.

Messrs. Paul & Son, Cheshunt, contributed a group of *P. acaulis* varieties, *alba plena*, major, *Croussei* purpurea, and others, together with many choice species and a few *Androsaces*. Miss Jekyll, Munstead Grange, Godalming, exhibited a number of varieties of the common Primrose, arranged in moss to form a bank, which some considered very tasteful. E. G. Loder, Esq., Floore Weedon (gardener, Mr. C. J. Goldsmith), showed sixty pots of Primulas, representing most of the best species in flower at this time, and some of which have already been noted. Mr. F. W. Moore, Royal Botanic Gardens, Glasneven, Dublin, had eighteen varieties of Primulas, which had suffered considerably in transit. Mr. T. S. Ware, Tottenham, supplied an extensive collection of miscellaneous hardy flowers, together with many Primulas arranged in the groups adopted by Stein. About 109 species and varieties were represented, but only a few of these were in flower. Smaller collections were contributed by Mr. J. Poë, Nenagh; Mr. P. J. Worsley, Clifton; Professor Kanitz, Kalossvar, Hungary; and from the Society's Gardens, Chiswick. Messrs. G. Bunyard & Co., Maidstone, showed some hose-in-hose Polyanthus; Mr. G. Lee, Clevedon, a plant of *Primula cashmeriana*; Miss C. M. Owen, Knockmullen, Gorey, Ireland, a variety of *P. vulgaris* with green flowers; Messrs. R. Veitch & Son, Exeter, had several white and blush varieties of *P. acaulis* from the open ground; the Hon. and Rev. J. T. Boscawen, Lamoran, Probus, Cornwall, exhibited fifty bunches of wild Primroses most varied in colour, white, yellow, rose, lilac, and crimson; and Mr. W. Roupell, Roupell Park, had a basket of seedling Auriculas, differing greatly in their tints.

Several species and varieties of Primulas were certificated, and amongst them the small *P. mistassinica* already noted in Messrs. J. Veitch & Sons' collection, and a grand variety of *P. rosea* from Mr. J. T. D. Llewellyn; but particulars of the others which were unnamed must be reserved to our next issue.

**Miscellaneous Exhibits.**—An imposing group of forty dwarf and standard Roses was shown by Messrs. Paul & Son, Cheshunt, the plants being strong, healthy examples, with vigorous foliage and fresh bright blooms, the best we have seen this season. Innocenti Pirola, Beauty of Waltham, La France, Hippolyte Jamin, Souvenir d'un Ami, White Baroness, Catherine Soupert, Senateur Vaisse, and Mad. de Montchateau. Messrs. Barr & Son, Covent Garden, had one of their extensive groups of Daffodils in all the best varieties. Mr. B. S. Williams, Upper Holloway, staged a choice group of stove and greenhouse plants, Orchids, Ferns, Palms, &c. Messrs. J. Pearson and Son, Chilwell, showed twenty-four varieties of Zonal Pelargoniums, exceedingly bright; and Messrs. H. Cannell & Sons, Swanley, had a group of double Cinerarias, purple and crimson, the blooms very full and bright. Messrs. J. Cheal & Sons, Crawley, exhibited a collection of sixty-four dishes of Apples, the fruits fine, firm, and handsome; it is seldom, in fact, that such well-kept Apples are exhibited at this time of year. Some of the varieties best represented were Alfriston, Curl-tail, Reineette du Canada, Blenheim Pippin, Emperor Alexander, Ribston Pippin, Winter Queening,

Lady Henniker, Royal Russet, Betty Geeson, Mère de Ménage, Gloria Mundi, Cox's Orange, Winter Pearmain, Cellini, and Lane's Prince Albert. The other not competing exhibits, chiefly Auriculas and Polyanthus, are referred to in the report of the Auricula Show.

## THE NATIONAL AURICULA SHOW (SOUTHERN SECTION).

APRIL 20TH.

THE annual Show at South Kensington opened on Tuesday last, but, owing to the northern growers being unable to compete, it was not so thoroughly representative as those in preceding years. The season has been a most trying one, the plants were late, it became necessary in many cases to employ a little extra heat to bring the flowers out in time for the Show, and the result was seen in the long-drawn truss stems which characterised nearly every collection. There was also in several cases a roughness in the blooms which generally accompanies the other evils induced by unduly hastening these plants, for the best grown Auriculas can only be had in true exhibition form when brought on as gradually and naturally as possible. Amongst so many there were of course some exceedingly handsome plants, and that selected as the premier Auricula—Headly's George Lightbody in Mr. J. Douglas's first-prize twelve—was a superb example of that fine variety. The truss was stout and bore nine large but clean even pips, beautiful in outline, with edge, body colour, and paste well proportioned, and tube bright. This variety was far the best in the classes, and the plant well merited the honour.

Seedlings were not numerous shown, and only four prizes were awarded as follows:—In the edged classes to Mr. J. Douglas for Snowdown's Knight, a white-edged variety of his own raising, a medium-size flower with a good edge, dark body colour, solid, pure, and well-defined paste, and a bright tube; and to Mr. J. T. D. Llewellyn for Charles Warrington, a grey-edged variety with a strong truss of five large pips, all the parts well proportioned and with a very bright tube. Mr. H. Bolton obtained two prizes with self; Mrs. W. H. Bolton (Bolton), very deep maroon, nearly black, and Mrs. Wilson (Bolton), violet purple, the pips of great size. Both are beautiful varieties of good quality.

### SHOW AURICULAS.

In the class for twelve Auriculas the champions usually try their skill, and so it was this season, but the absence of the Rev. F. D. Horner lessened the interest of the competition, which was confined to Mr. J. Douglas, gardener to F. Whitbourn, Esq., Great Gearies, Ilford, and Mr. C. Turner, Slough, who were awarded the first and second prizes in the order named. The varieties in the premier twelve were Campbell's Pizarro, Simonite's Rev. F. D. Horner, Trail's Prince of Greens, Douglas's Mabel, Duke of Albany, Verdure, and Conservative, Leigh's Colonel Taylor, Heap's Smiling Beauty, Turner's C. J. Perry, Headly's George Lightbody, and Dr. Horner. All the plants were somewhat "drawn," but Mr. Douglas gained in freshness and substance. The same exhibitors held the similar positions in the class for six Auriculas, but were there followed by J. T. D. Llewellyn, Esq., Penllergare, Swansea, and Mr. Hardwidge, 1, Martineau Road, High-bury Hill, N. Nine competitors entered with four varieties, Mr. T. E. Henwood, Earley, Reading, leading with Horner's Sapphire, Lancashire's Lancashire Hero, Douglas's Conservative, and Headly's George Lightbody, strong plants with good blooms. The other prizes in that class were awarded to Mr. C. Phillips, Earley, Reading; A. Potts, Esq., Hoole Hall, Chester; Mr. W. C. Walker, Reading; and Viscountess Chewton, Bookham Lodge, Cobham (gardener, Mr. A. J. Sanday), in the order named. With two varieties ten exhibitors entered, Mr. A. Potts leading with Headly's New Green and Read's Acme. Mr. C. Phillips; H. A. Rolt, Esq., 170, Hartfield Road, New Wimbledon; J. Galsworthy, Esq., Coombe Warren, Kingston (gardener, Mr. C. Orchard), and Mr. W. C. Walker following closely.

**SINGLE SPECIMENS.**—The entries in these classes were not so numerous as usual, and the Judges had less difficulty in making their awards, the prizes going as follows:—*Green-edged*—Mr. C. Turner, first and second with George Lightbody and Lancashire Hero; Mr. J. Douglas third and fourth with Prince of Greens; Mr. Henwood fifth with Colonel Taylor; and Mr. Potts sixth and seventh with New Green and Prince of Greens. *Grey-edged*—Mr. C. Turner first and fourth with George Lightbody and Richard Headly; Mr. J. Douglas second and third with George Lightbody; Mr. W. G. Walker fifth with Richard Headly; and Mr. C. Phillips seventh with George Lightbody. *White-edged*—Mr. A. Potts first and fifth with John Simonite and Beauty; Mr. J. Douglas second and third with Acme and Conservative; Mr. C. Turner fourth and sixth with Acme and True Briton; Mr. Henwood seventh with Acme. *Selfs*—Mr. Bolton first and fifth with Black Bess and a seedling; Mr. Henwood second with Pizarro; Mr. C. Turner third and sixth with C. J. Perry and Lord of Lorne, and Mr. Potts seventh with the same variety.

In the class for fifty Auriculas, not less than twenty varieties, Mr. J. Douglas and Mr. C. Turner were the only exhibitors, being placed respectively first and second, the former having a larger proportion of edged Show varieties, while in the Slough collection selfs were prominent.

### ALPINE PLANTS.

The classes devoted to these are invariably more attractive to the general public than the Show varieties, which are so highly appreciated by the florists. The Slough collection is particularly strong in Alpines, and Mr. C. Turner has usually scored well in these classes. On this occasion the giants from the same establishment were first both for twelve and six varieties, the former comprising Sceptre, Edith, Unique, Sir H. Darvill, J. T. Poe, Sensation, Princess of Wales, Mrs. Thomson, J. J. Colman, Hotspur, Charles Turner, Athlete, all, we believe, having been brought out by that firm. The leading varieties in the smaller class were Progress, Mrs. Ball, Paragon, Mrs. Pope, Mrs. Thomson, and Edith. The second prizes being secured in each class by Mr. J. Douglas, Mr. R. Dean third, and Mr. C. Orchard fourth with six. For a single specimen gold centre Mr. C. Turner was first and fifth with Sunrise and John Ball, Mr. J. Douglas second and third with Rosamond, and Mr. R. Dean fourth with Mrs. Thomson. The prizes in the corresponding class for white or cream centre varieties being secured by the following—Mr. C. Turner first and third with

Marguerite and Miss Taplin, Mr. R. Dean second with Tenniel, and Mr. J. Douglas fourth and fifth with Lady Howden de Walden.

#### POLYANTHUSES AND MISCELLANEOUS.

The Polyanthuses were not so numerous or good as usual, that fine variety Cheshire Favourite standing out prominently amongst them. There were two entries of six gold-laced Polyanthuses, but one of these was disqualified because some of the flowers were pin-eyed; the other was from Mr. J. Douglas, who was adjudged the first prize, his varieties being Sanderson's Henry I., Barlow's John Bright, Sanderson's William IV., Cox's Prince Regent, Buck's George IV., and Lancashire Hero. For three varieties Mr. Walkden was first, showing Exile, Cheshire Favourite, and a seedling, Mr. J. Douglas and Mr. J. T. D. Llewelyn following. Mr. Walkden was also first in single specimen class with Cheshire Favourite, Mr. R. Dean third, fourth, and fifth with George IV., Prince Regent, and Lancer; Mr. J. Douglas being sixth with Formosa.

Fancy Auriculas were well shown by Messrs. Douglas and Bolton, who won the first and second prizes. Mr. R. Dean and Messrs. Paul & Son were the prizetakers for twelve Fancy Polyanthuses, both exhibiting brightly coloured varieties, and the same exhibitors were placed in like order for twelve double and single Primroses of similar merit to the foregoing. Mr. J. T. D. Llewelyn had an admirable premier collection of Primulas in the class for twelve not less than six distinct species, Mr. J. Douglas taking the second place with smaller plants.

#### SPRING-FLOWERING HEATHS.

THOUGH large numbers of such *Ericas* as *hyemalis* and *gracilis* are now grown, many very beautiful species are much neglected. It is easy to have a number in flower at this time of year which would be welcome in greenhouses and conservatories to relieve the monotony of ordinary forced bulbs and other plants. The following is a selection of half a dozen easily grown Heaths that should be in every collection:—

*E. colorans superba*.—A shrubby erect-growing softwooded kind, having linear obtuse downy light green leaves arranged in fours. Flowers

Fig. 54.

produced in clusters towards the ends of the branches, and forming dense racemes of tubular bell-shaped pendulous blooms, which are pure white in a young state, but change with age to rose colour (fig. 54).

*E. regerminans*.—A twiggy, compact, softwooded plant of free growth. Leaves arranged in fours, linear, obtuse, and dark green. Flowers small, bell-shaped, produced in clusters at the ends of all the branches, pale purple in colour, and sweet-scented.

*E. Linnaeana superba*.—A robust-growing variety of great beauty. Leaves arranged in threes, linear, obtuse, and villous. Flowers large, tubular, hirsute, terminal on the small branches, forming long dense racemes lower portion of tube rosy purple, mouth white.

*E. canaliculata*.—Leaves in threes, linear, obtuse, plain above, channelled below, and deep green; the footstalks long and coloured. Flowers nodding, bell-shaped, in threes at the ends of the small branches pale purple in colour.

*E. campanulata*.—An elegant slender-growing plant. Leaves sub-

Fig. 55.

ulate, smooth, and arranged in fours, light green. Flowers pendant, usually solitary, bell-shaped, and clear yellow (fig. 55.)

*E. persoluta*.—Leaves linear, obtuse, light green. Flowers small, bell-shaped, produced in great profusion upon all the small branches, and forming long and dense racemes of a deep blush colour. There are two varieties of this plant—viz., *alba* and *rubra*, the former producing pure white, and the latter deep red flowers.—G. W. H.

#### AMMONIA IN VINERIES.

A GENTLEMAN who has of late years devoted many of his leisure hours to the pleasurable occupation of gardening, and who is particularly interested in Grape culture, has arrived at the conclusion that an artificially-created ammonia-charged atmosphere must be beneficial to the contents of the vinery. As far as he was concerned the idea was original enough, but as many readers of this Journal are aware it is far from being novel, though I believe very few modern gardeners now think of affording the Vines any food through their leaves, and not a few would argue against the possibility or advisability of so doing. In any case I have promised to give my own views on the subject, and am open to contradiction or correction if they are found to be incompatible with the theories or practices of men qualified to express an opinion on the matter.

According to chemical authorities the atmosphere consists principally of two gases—nitrogen and oxygen, with small portions each of aqueous vapour and carbonic acid gas. In addition it also contains a small portion of ammonia, and in places near the sea muriatic acid. The quantity of aqueous vapour varies exceedingly with the temperature and the locality, but the proportions of nitrogen, oxygen, and carbonic acid gas are nearly constant at all temperatures and in all situations. It thus appears that we may easily dissipate the aqueous vapour and ammonia, and which we most frequently do in our dry overheated houses. By occasionally damping the floor, walls, and stages of our houses we maintain the requisite moisture in the atmosphere; but how often do we think of replacing the ammonia driven

out of the top ventilators? Ammonia is created by the natural decomposition of animal and vegetable substances, but being naturally light ascends very rapidly, especially in a somewhat dry atmosphere. It is brought back to the earth by the rains, the latter also absorbing some of it, hence its softness and superiority for watering and other purposes. Who of us has not revelled in the smell accompanying rain falling after a spell of dry weather, or who has failed to observe how rapidly plants grow under its influence? It is the ammonia we detect, and it is this, accompanied with an increasing amount of aqueous vapour, that proves so favourable to vegetation generally. What is to prevent us imitating or even improving on Nature in this respect, as we like to flatter ourselves we are always doing in other ways?

No one with any practical experience will dispute that Vines are apt to break strongly, evenly, and quickly when under the influence of aqueous vapour and ammonia. The vapour has too long had the credit for this good work, when in reality much of it is due to the ammonia, with its softening influence accompanying it. While this heap of manure and leaves remains in the house the frequent syringings and dampings serve to hasten decomposition, and a small quantity, it may be sufficient, ammonia is given off, but it is usually removed soon after the Vines have commenced active growth, and no other steps are taken to provide the necessary supply. I repeat necessary supply, as I am of opinion that a certain quantity is most beneficial, and further ammonia is very frequently more absent in vineries than it is the various forcing and plant-growing structures, where both liquid and artificial manures, in which ammonia largely predominates, are employed at certain intervals. When plants of Cucumbers and Melons are approaching the trellis of a house they make much more rapid progress than heretofore, and the foliage and stems increase in size and thicken surprisingly fast; while the Grape leaves are always the finest and thickest in texture at the top of the house. In one case the increased amount of heat and light to which they are subjected has the credit for this improvement, and the largest share of the sap with more air is usually considered the principal agents in the formation of this superior foliage, coupled with larger bunches of fruit; but who can positively assert that the ammonia, which is bound to accumulate at the highest points, does not materially benefit the foliage and plants in each instance?

If we are allowed to take it for granted that ammonia in the atmosphere does act most beneficially upon plant life, what we have next to determine is the quantities that the leaves imbibe, the amount in excess that would prove injurious, when and to what it would prove injurious, and how best to keep up the requisite supply in our vineries. It is in these respects we require the assistance of others more experienced, as well as scientific readers, and I hope to gain some useful information on the subject. That it will do good I have had fair opportunities of observing, independent of what is done by Nature in the open, and that an incautious use of materials highly charged with ammonia will work much mischief I have also had good evidence of, though not in vineries after the foliage is developing. One excellent and well-known gardener that I served under was a firm believer in the advantages attending an artificially created ammonia-charged atmosphere, and in those days he grew Black Hamburgh and other Grapes to perfection, and won several good prizes with them. Another gardener, an old master and friend of mine, who cultivates Grapes still more extensively, and annually wins numerous prizes at some of the best shows in the country, also has his own method of keeping up the supply of ammonia, believing this to both benefit or feed the foliage, and also act as a preventive of red spider. The first-mentioned gardener used to fill the evaporating troughs on the hot-water pipes with fresh horse manure, and in this manner the aqueous vapour and a good supply of ammonia, quite sufficient in fact, was maintained. In the other instance the floors of the houses were damped down twice a week with weak guano water, and this again is a safe and sure method of supplying ammonia, and much preferable, as being agreeable to the senses, than farmyard liquid manure, though the latter contains a great amount of ammonia. I should not think of attributing these successes in Grape culture solely to this practice of charging the atmosphere with ammonia, as this was only one important detail in a generally good routine.

It remains to be added that the ammonia is assimilated by the leaves when these are considerably advanced and capable of performing their functions, and that only small quantities are thus absorbed. Consequently it will be seen that frequent small doses or a constant weak supply is both preferable, and, as I shall attempt to prove, much safer than an occasional strong dose. As before stated, no case of injury to Vines from an overdose of ammonia has come under my notice, but I have seen some perilously narrow escapes. A friend of mine has the advantage of being able to secure good supplies of covered farmyard manure, and this is so very rich in ammonia that a liberal top-dressing to a Vine border in an early house gave off, when the house was first closed and damped down, sufficient to fetch off all

the leaves on strong plants of white Indian Azaleas, as well as other plants, being forced; but as the Vines were not in leaf no mischief resulted to them. Here we have injured the foliage of Tomatoes by an incautious addition of soot to soil with which lime had been freely mixed before it was carted to us, this at the time being our only available loam. Having previously observed how much injury was done by confined fumes of ammonia from soot with which lime has come in contact, a repetition of this occurrence would not have happened had I been aware of what was going on. Probably others can give more striking instances where ammonia in excessive quantities has proved most injurious, and I can easily imagine that both the delicate foliage and newly set berries of the Grape would be the first to suffer from it.—W. IGGULDEN.

[There is much danger in the excessive use of ammonia in vineries when the foliage and fruit are in the condition indicated—namely, young and tender.]

## THE DAFFODIL.

[A paper by the Rev. C. Wolley Dod, read at the Horticultural Club, April 14th.]

I HAVE been asked to open a discussion on the Daffodil. I therefore confine myself to the Daffodil proper. The subject of these notes is the Trumpet or Ajax Daffodil (*Narcissus Pseudo-Narcissus*) and its varieties. First as to the name Daffodil. In old English, say Parkinson's time, nearly 300 years ago, the word Daffodil was used as an equivalent of the Latin and Greek flower name *Narcissus*. The *N. poeticus*, the *N. tazetta*, the *Jonquil*, the *N. triandrus*, and the rest of that class were all called Daffodils, whilst to the Trumpet Daffodils the name *pseudo-Narcissus* or False Daffodil was given. Usage, however, has transposed these names. We now call the Trumpet flowers Daffodils, and most of the other kinds *Narcissus*, and it is not desirable to interfere with usage in these matters, or to try to force changes of popular names. By the name Daffodil, therefore, we mean the Trumpet Daffodil, excepting, however, the Hoop Petticoate, which, though anciently called *Pseudo-Narcissus* by Clusius and others, are quite distinct in kind. Of these Trumpet Daffodils, Linnaeus, who wrote in the middle of last century, made five species; and Haworth, who wrote half a century ago, and whose nomenclature has been in a great measure adopted both by English and by foreign botanists, made twenty-nine species.

Mr. Baker, however, in a review of the genus *Narcissus*, written seventeen years ago, includes all the Trumpet Daffodils in one species called *N. Pseudo-Narcissus*, retaining, however, the five Linnæan species of it as sub-species or sections, under which he classes, with Haworth's names, the principal known wild varieties. I shall follow this arrangement, giving reasons, however, for one or two exceptions. I shall use the name *Pseudo-Narcissus* in three ways, distinguishing as follows:—

- 1, *Pseudo-Narcissus* the species, including all the Trumpet Daffodils.
- 2, *Pseudo-Narcissus* the sub-species or section, as admitted by Mr. Baker;
- and 3, *Pseudo-Narcissus* the type, the average form of the English wild Daffodil or Lent Lily—the Garland of old writers. Most of you are well acquainted with the technical terms for the different parts of the Daffodil, but as there may be a few here who are not, I will spend two or three minutes in defining them, that what I say afterwards may be more clearly understood. I need not define the bulb.

The flower stalk as high as the first joint is called the scape. The scape in the species *Pseudo-Narcissus* is usually one-flowered, but in a variety, or sub-species, called *muticus*, it is sometimes two-flowered. In most varieties two-flowered scapes are rare. The normal, or regular scape, is straight and upright, but in the form of minor, being slender, apt to bend downwards. The scape in *pseudo* is more or less compressed or acapitous, and more or less hollow.

THE LEAF.—This varies in breadth from a quarter of an inch in the form called *minimus*, to an inch in some varieties of the section *bicolor*. It also varies much in thickness. The breadth is not always in proportion to the thickness or length of the leaf, or to the height or size of the flower. The leaves of some varieties are much twisted. In some they are far more conspicuously covered with glaucous bloom than in others. Some taper acutely at the ends, some are very bluntly rounded off, some decumbent, some upright. I cannot find any variety of form in leaf cross sections. As for the number of leaves to each flowering scape, I find that about 70 per cent. have three, the remaining thirty are nearly equally divided between two, four, and five leaves. In the section *bicolor*, however, the larger number of flower scapes have four leaves belonging to them, and some as many as seven. In estimating this number care must be taken not to confuse the leaves belonging to different centres of growth in the same bulb. A bulb may produce only one flower scape and twenty or more leaves, but then there are three or four centres, each of which will develop a new bulb as the growth matures.

At the top of the scape there is a sort of joint or valve, where begins a membrane called the spathe, which entirely envelopes the flower whilst in bud. It sometimes fits tight and close, sometimes is very loose, either at the base or at the point, or both, as if far too large for the bud it encloses. Beginning also at the valve of the spathe is a distinct stalk, more slender than the scape, called the pedicel. Two-flowered scapes have two pedicels, but only one spathe. The pedicel connects the scape with the seed pod or fruit. It is mostly in this pedicel that the bending or deflexion takes place upon which depends the angle of the flower to the scape. The pedicel may be quite straight or turned at right angles to the scape at the spathe valve, or bent into a complete semicircle, or any interme-

diate form. The commonest form is that of a quadrant, or fourth part of the circumference of a circle. The seed pod, which we will call the fruit, is round or elliptical—i.e., oval, furrowed, or smooth, and should be studied when swelled to its full size.

Immediately above the fruit is that part of the flower in which the base of the style and the filaments are fixed, and which in *Pseudo-Narcissus* is like a funnel or an inverted cone. This is called the tube. It is important to remember this name, because we often find the word tube wrongly applied to the part I shall next describe—viz., the trumpet, called by some botanists the trunk, but which I shall speak of as the corona or crown. This begins where the tube ends, and from the line of juncture of the tube with the corona there grow out six flower leaves, sometimes called limbs or segments, but which I shall call divisions of the perianth. They correspond to petals and sepals alternately; the three which represent sepals generally overlap at their edges and have the three inner, which represent petals. When this is so the divisions of the perianth are said to be imbricated (which properly means arranged like the tiles on the roof); but if the divisions when closed so as to touch the corona do not overlap, especially near the base, they are said to be not imbricated or free. I ask you to attend especially to the above important character.

Next we find that the divisions are sometimes shorter than, generally just the same length as, often a little longer than the corona. The perianth divisions are often twisted, or in some forms doubled back along the central line, and curved like a horn towards the end of the corona. The shape of the corona is rather cylindrical, the sides when looked at in profile being parallel, or it approaches a funnel in shape, the boundary lines diverging from the base to the mouth, or (rarely) it is larger at the middle than at either end, its shape is then called ventricose. The mouth of the corona varies more than any other part of the flower in the forms of *Pseudo-Narcissus*. In some forms we find at the mouth hardly any enlargement in the diameter of the straight corona; more commonly the corona bulges out near the mouth, but without turning back, whilst in many varieties the mouth spreads and is recurved like the mouth of a trumpet. Recurved is a better word to express this form than reflexed, which implies an angular and less gradual turn. The petals of a *Cyclamen* are reflexed, those of a *Martagon* recurved. With rare and abnormal exceptions the mouth of the corona is divided by incisions—more or less deep according to the variety—into six equal lobes corresponding to the six divisions of the perianth. When the flower becomes double these divisions or incisions are continued to the base of the corona, so as to split it up into six parts. The lobes are often cut up at the edges by irregular notches, generally wedge-shaped, and varying in depth, into smaller divisions of uncertain size and number. This is called crenation, and the lobes are then called crenate—that is, notched. When the parts between these notches are doubled up together like a piece of crimped paper, or a nearly closed fan, the edge of the corona is called plicate (or folded), and when these folds are pushed together so as to displace one another into a sort of flounced or puckered outline, it is called crispate (fringed or fimbriated), the edge then resembles a leaf of garden Parsley or Curled Kale. It is a rare form.

Now, what are these characters worth in estimating varietal differences? Not much taken singly, but several together, if found to be constant, are worth a good deal. Some who have studied Daffodils have thought the mouth of the corona so important a character as to supersede all others in deciding varieties. Next to this in importance comes, I think, the arrangement of the perianth divisions, the question whether they are imbricated or free. The length of the pedicel is moderately constant, according to the variety. The relative length of the style and the filaments often differs in the same variety, but Herbert, a careful botanist who studied Daffodils about the same time as Haworth, thought that he had observed that in some varieties of *Pseudo-Narcissus* the six filaments are attached to the base of the tube in two different rows. This arrangement of the filaments in a double series is an obvious character in many species of *Narcissus*; but after examining a large number of *Pseudo-Narcissus* I have not been able to discover that any difference of length of the six filaments exists in any variety. This should be observed. The same botanist, Herbert, attached importance to the wrinkling or furrowing often observable in the fruit and to its shape; neither is very constant, but both are worth notice. The comparative length of the perianth divisions and the corona often varies in the same variety, as anyone who will spend a little time amongst a bed of English wild typical *Pseudo-Narcissus* may satisfy himself. The form of the spathe before opening is also to be noticed. Some varieties may be recognised by this alone. Another distinction, though by no means constant, is the curvature of the pedicel. When the flower is fully expanded, the corona becoming either cernuous—that is, looking downwards, or horizontal, or even perpendicular; the pedicel remaining straight, though this form is generally abnormal; the angle which the perianth divisions, when open, make with the corona is also a character. I find neither the section of the scape nor of the leaf a trustworthy varietal character in *Pseudo-Narcissus*. In *Pseudo-Narcissus* as a species colour is an important point. The varieties are either concolorous or bicolorous—i.e., either self-coloured, the corona, however, being always a little deeper than the perianth, or distinctly two-coloured. The English wild type is never, as far as I know, concolorous, and varies in colour within narrow limits; apparent exceptions to this rule which sometimes occur I believe to be due to cross-breeding. I shall speak of them presently.

Daffodils of the same variety rarely vary much in colour. A form of *N. minor* found near Grosse in the Maritime Alps is an important and interesting exception to this rule. It remains to speak of size and time

of flowering. To judge of the former, Daffodils must be grown together for a year or two under the same conditions; and as for time of flowering, I find that the time when different individuals of the typical form open their flowers extends over a month, and though the same bulbs are early or late every year alike, one cannot attach importance to the difference.

(To be continued.)

WE have received a copy of the list of the subscribers to the GARDENERS' ROYAL BENEVOLENT INSTITUTION, which also contains the report of the Committee for 1885 and a financial statement for the same period. From this it appears the annual subscriptions amount to £1204 13s., the donations to £771 3s. 6d., and the legacies from Mrs. Dodgson (£450) and J. Sutherland Law, Esq. (£100), to £550: £1655 1s. 4d. has been paid in pensions, and the balance remaining exclusive of the invested capital is £387 5s. 9d.

— DR. PATERSON, Bridge of Allan, sends a fine bloom of Sir Trevor Lawrence's variety of *DENDROBIUM BRYMERIANUM* from a small plant with seven pseudo-bulbs and one growth, the last-made pseudo-bulb 2 feet high, which is somewhat unusual.

— THE usual monthly dinner and conversazione of the HORTICULTURAL CLUB were held at the rooms, 1, Henrietta Street, Covent Garden, on the 14th inst., when there was the largest attendance of members that there has been during the present session. Those present included Mr. John Lee, Chairman, the Rev. C. Wolley Dod, the Rev. F. H. Gall, Dr. Hogg, Messrs. H. J. Veitch, Cousins, George Paul, W. J. Jefferies, T. W. Girdlestone, J. D. T. Llewelyn, George Prince, C. P. Wheatstone, C. T. Drury, R. B. Cater, T. P. Collings, J. T. Cooling, C. Pearson, &c. The discussion was opened by an interesting paper by the Rev. C. Wolley Dod on the *Pseudo-Narcissus* section of *Narcissus*, and was continued by Messrs. Llewelyn, G. Paul, Dr. Hogg, Cousins, and others. The discussion at the next meeting will be opened by Mr. George Paul on the Bog Garden.

— IT will be observed by an advertisement in another column that our correspondent Mr. GEORGE ABBEY is disengaged. In a letter before us his late noble employer expresses his appreciation of Mr. Abbey's services and testifies to his admitted ability; and we know that he is as active and industrious in his habits as he is competent in his vocation. We trust that a gardener so experienced will soon be in harness again, and have scope for the exercise of his skill both as a cultivator and an improver of grounds and gardens.

— THE programme of arrangements issued by the CRYSTAL PALACE COMPANY, SYDENHAM, gives the following as the dates of the Horticultural Exhibitions to be held there this season:—Summer Show, at which forty-five classes are provided, Friday and Saturday, May 21st and 22nd; Rose Show, twenty-eight classes, Saturday, July 3rd; Fruit and National Dahlia Show, September 3rd and 4th; Hardy Fruit and Vegetables, October 6th to 9th, with which the National Potato Show will probably be held, and a Chrysanthemum Exhibition, November 5th and 6th, when there will also be an exhibition of Canadian and Nova Scotian Apples. Exclusive of the Spring Show which is past, a series of five exhibitions is thus provided, at all of which the prizes are liberal in amount. The Horticultural Superintendent is Mr. W. G. Head.

— THE remarkable YELLOW ODONTOGLOSSUM PESCATOREI shown by Mr. Brownlow Knox at South Kensington last week and then certificated, was sold by auction at Mr. Stevens' Rooms on the following day. After a sharp competition it was knocked down to Baron Schroder for £165, and will form an important addition to the many choice Orchids in that collection.

— TOBACCO CULTURE.—Under authority from the Lords of the Treasury the experimental cultivation of Tobacco is to be permitted in the United Kingdom. Any occupier of land intending to plant Tobacco must, on or before the 5th May, give notice to the Secretary of Inland Revenue, Somerset House, setting forth the extent of the land to be planted, and the place, parish, and county where situate. Bond under

approved securities will be required in a penalty of £100 if over an acre of ground is cultivated, and £50 if under an acre, in order to secure that all Tobacco grown and gathered shall be removed to drying rooms and kept there until properly cured, when it shall be packed in bags, bales, or casks of an approved size, and must then be weighed by a revenue officer. After weighing the packages the duty must be paid, or the Tobacco be deposited in an approved Customs or Excise warehouse. An experiment both in the cultivation and preparation of Tobacco will be conducted in the Royal Horticultural Society's Gardens at Chiswick this year under the superintendence of a gentleman who has had experience in the work. Messrs. James Carter & Co., 237, High Holborn, have published a pamphlet in which is embodied a considerable amount of information on the culture and preparation of Tobacco, including cost of production and value of the crop in Belgium.

— WE have received from Messrs. James Dickson & Sons, Newton Nurseries, Chester, blooms of the new Narcissus *SIR WATKIN*. They are very large and handsome, and there is no doubt that this is one of the finest and most effective varieties in cultivation.

— WE are informed that the Council of the Royal Horticultural Society have kindly granted the services of their Chief Clerk, Mr. J. DOUGLAS DICK, to the Royal Commission of the Colonial and Indian Exhibition to act as their Superintendent of Entrances during the Exhibition—a responsible position which Mr. Dick has filled satisfactorily at previous exhibitions at South Kensington.

— THE TWO FINEST POT NARCISSUS.—Opinions will always differ as to colour. I prefer those with white perianth segments and trumpets some shade of yellow—that is, belonging to the bicolor section. Of these *N. bicolor Horsefieldi* comes first in point of time if not in size and beauty. It bloomed with me this year the 10th March without forcing treatment, and lasted until succeeded by *N. bicolor Empress*. Those answer admirably for succession, and now, when the pot plants will have ceased blooming, they will be followed by those in the borders. If pure yellows are preferred, as seems to be now the fashion in London, *Lorifolius Emperor* comes first in tinting and brilliancy. It is now in bloom here.—W. J. MURPHY, *Clonmel*.

— MR. W. ALLMAN, Lymm, sends us blooms of *CHRYSANTHEMUM FAIR MAID OF GUERNSEY* to show what a good late variety it is. He has been gathering similar flowers every week during the winter from two plants, and there are several buds to open yet. The blooms received are very fresh and attractive.

— FLOWERING OF PEACH TREES.—As no one has noticed "T. F. R.'s" complaint on April 8th, the failure does not seem to be general. My experience this season is quite the reverse of his. Our trees both in pots and planted out in late houses have just shed their flowers and have set remarkably well. My employers tell me they have never had such an abundant lot of flowers on them before. The early houses also have first-rate crops, and the first fruit of *Early Beatrice* is ripe to-day, April 17th. Some large trees of *Alexander* and *Waterloo*, &c., removed from the houses to a south-east wall last autumn, are also very full of flowers. As regards the frost causing the damage to "T. F. R.'s" trees, the temperature of our houses when at rest never goes below 32° as a rule, but once this season we had 6° of frost in for two or three hours.—W. H. DIVERS, *Ketton Hall*.

— A CORRESPONDENT, "L. W.," The Gardens, Cookridge Tower, Leeds, sends the following notes:—"SAXIFRAGA OPPOSITIFOLIA SPLENDENS.—It is impossible to speak too highly of the beauty of this bright little Saxifraga, so distinct with its purple rose colour flowers, which it shows to the best advantage with us as it is growing in a rock bed on the lawn. The flowers are solitary, on short erect stems, and are so thickly produced as to quite hide the leaves, which are small, opposite, and densely crowded. We have several varieties of the *Saxifraga oppositifolia* in flower at present, but none so brilliant in colour as *splendens*. We have them planted by the side of a rock and fully exposed to the sun, where we find they grow well. They like a good open rich loam."

— "A VERY rare and minute alpine plant, *SOLDANELLA MINIMA ALBA*, is flowering with us. It has minute round leaves and one flower on a stem, drooping and fringed a portion of its length. Being much smaller than the other *Soldanellas* it requires more care in planting, and should be planted with the most minute alpine plants in a mixture of peat, loam, and sharp sand, and where it will be moist in summer."

— SCIENCE IN HORTICULTURE.—Please allow me to say that the position I hold in relation to "A Lover of Fair Play," page 290, does not admit of my discussing the subject further than to say that I did not intend to be "incorrect or unjust" in my criticism on foreigners, and as he evidently feels aggrieved at my remarks and applies them personally, I wish to express my regret, and assure him that they were not so intended. With regard to what I stated about a noted foreign gardener objecting to employ students from the School of Horticulture at Versailles, my information was from what I considered at the time I wrote an authentic source, but not being at liberty to name it, I must allow that "A Lover of Fair Play" is right and I am wrong.—YOUNG PRACTICALIST.

— THE WROXTON OR HOWARD'S ONION.—Mr. W. Iggulden writes:—"Your esteemed correspondent Mr. Easty asks for the history of this novelty, and I fully expected someone would point out that Mr. Finlay is presumably the raiser, he having named the Onion after the place where he was at one time acting as gardener. To tell the truth, I have long been a little curious in the matter, but waited before seconding Mr. Easty in his request for full information to see if Mr. Finlay or one of his friends would supply us with the facts of the case. Is Mr. Finlay prepared to assert that he actually raised the variety in question? For my part I am strongly under the impression that it is an old friend of mine; at any rate the two, as grown by me last season, could not well be separated, and, strange to say, both are of the same parentage. If I am right in my surmises, the name I have it under—viz., Howard's Onion—is correct, and the Wroxtton ought to be removed from our catalogues."

— MAJOR CAREY favours us with an interesting note on *CHRYSANTHEMUMS AND FLOWERS IN GUERNSEY*. "On reading your number of April 8th, I notice among the list of Japanese *Chrysanthemums* the variety named 'Ethel,' and that the name of the raiser is not mentioned. I beg to inform you that it was raised by me in the year 1876 and sent out by Mr. Dixon. I consider it one of the best varieties, as it never loses its pure whiteness, and the dark centre is almost unique. Another of my seedlings, Mrs. C. Carey (raised in 1880 and sent out by Cannell), does not seem to meet in England with the attention it deserves. It is the best late variety, and most floriferous, and also has the advantage of retaining its whiteness until faded. In this island many gardeners grow from 700 to 1000 plants for flowers for exportation, and the number of blooms obtained from each plant is most remarkable. By cutting down the plants of this variety and placing them in heat you can get a second blooming, and last week I was shown six plants which had been thus treated covered with most perfect snowballs, and from which the gardener expected to cut fifteen dozen blooms for the London market. Horticulture is carried on in Guernsey on a very large scale, and the daily steamers carry away tons of flowers to be distributed all over the United Kingdom. Camellias grow out of doors in astonishing profusion, and the more you cut the enormous bushes the more they bloom. One man assured me that he can cut daily 1000 blooms without his trees appearing stripped. Mr. Smith of the Caledonian Nurseries, the raiser of many incurved *Chrysanthemums*, devotes himself now to other branches, and his houses filled with beds of the lovely pure white and highly perfumed *Freelias*, his out-of-door beds of *Jonquils* and *Daffodils*, varying from white down to the deepest orange, his many-hued *Ixias*, looking in the sun like myriads of gorgeous butterflies, and his show of *Roses* are things to be seen to be believed in."

#### SELECT AURICULAS.

OUR illustration represents a selection of the best Auriculas, good typical examples of the most recent novelties in each class, except in the green-edged varieties, of which the best in all points is still *Trail's Prince of Greens*. They were sketched in Mr. F. Whitbourn's extensive and admirably grown collection at Great Gearies, Ilford, under the charge of Mr. J. Douglas, who has for so many years been a successful cultivator and exhibitor of Auriculas. A span-roof house 50 feet long is there devoted to these plants, and the varieties comprise the many fine seedlings raised by Mr. J. Douglas and the Rev. F. D. Horner, together with the older varieties, some of which have delighted florists for half a century or more. The season has not been a favourable one, and the artificial assistance needed to bring the flowers forward has caused in a few instances a slight roughness, but it is such as only the keenest critics would notice, and in general appearance the plants and blooms leave nothing to be desired. It would be a pleasure to refer at some length to the collection and the varieties, but our space is too limited this week to permit it, and further notes must be reserved till another issue.

The varieties shown in the woodcut are as follows:—1, Green-edge, *Trail's Prince of Greens*; 2, Grey-edge, *Silvia*; 3, Grey-edge, *General Graham*, remarkable for its large pip and truss and fine purple body

Fig. 56.—SELECT AURICULAS.—1, PRINCE OF GREENS; 2, SILVIA; 3, GENERAL GRAHAM; 4, CONSERVATIVE; 5, SIR W. HEWETT; 6, PRINCESS OF WALDECK; 7, PRIMULA AURICULA.

colour; 4, White-edge, Conservative; 5, Self, Sir W. Hewett, extremely dark, nearly black; 6, Alpine, Princess of Waldeck, bright red shaded; and 7, the wild *Primula Auricula*, the plant having been collected by Mr. Llewelyn on the Pyrenees. All these except the first and last have been raised by Mr. Douglas and certificated; *Silvia* having been honoured by two societies, Conservative by three, and the grey-edge Mrs. Moore (not mentioned there but included in the following lists) by four. Other varieties of Show Auriculas from the same raiser that have been certificated are Mabel and Marmion, both grey-edges, while of Alpine, Florence, Prince, J. H. Laing, Amelia, and Elwyne have been similarly honoured.

The following is a selection of six of the finest Show varieties in each class as grown at Great Gearies.

*Green-edge*.—F. D. Horner (Simonite), Prince of Greens (Trail), Colonel Taylor (Leigh), Admiral Napier (Campbell), Alderman Wisbey (Headly), and Verdure (Douglas) a new variety, one of the brightest clearest greens of all; the edge spotless, the flower and truss fine.

*Grey-edge*.—George Lightbody (Headly), *Silvia* (Douglas), Mrs. Moore (Douglas), Lancashire Hero (Lancashire), Richard Headly (Lightbody), and Mabel (Douglas).

*White-edge*.—Acme (Read), Conservative (Douglas), John Simonite (Walker), Smiling Beauty (Heap), True Briton (Hepworth), Glory (Taylor).

*Selfs*.—Sapphire (Horner), Duke of Albany (Douglas), Sir W. Hewett (Douglas), Negro (Brockbank), Pizarro (Campbell), and C. J. Perry (Turner).

In other houses and frames is also a choice collection of Primulas and Polyanthuses, which are mentioned in the report of the Auricula Show and Primula Conference, while throughout the garden at Great Gearies is a model of neatness.

### LIME FOR VINE BORDERS.

I SHOULD be very sorry for your correspondent "A. L. G." to think that I attribute to any unworthy motive the action he has taken in criticising my articles on this subject. The opposite is the case, and I admire him for his courage in attacking the subject I advanced. His remarks show that he is not a mere imitator, but exercises his thinking powers, and strikes out a course for himself. I did not intend referring to this subject again at present, whatever your correspondent's reply had been, for the object for which my first article was penned has been entirely overlooked. I wish to thank "A. L. G." for his criticism, and to insure him that I at least believe his motive in so doing to be thoroughly honest.—WM. BARDNEY.

### SWANSEA SPRING SHOW.

THIS was held in the Prince of Wales Drill Hall on April 14th and 15th. It is a spacious building with abundance of light coming in from the top and we have never seen a hall in which flowers were seen to greater advantage. The arrangements were all that could be desired, the Chairman and Treasurer being Captain Colquhoun, and the Hon. Sec. Mr. T. D. Lewis, both of whom were unremitting in their labours to make it a success, and they succeeded admirably. Here and there in the body of the hall groups of plants were arranged, chiefly in circles, and all round was banked up with many excellent foliage and flowering plants. In competing for a group of plants, which was the leading class, Mr. Warmington, gardener to J. T. D. Llewelyn, Esq., Penllergare, was accorded the first prize for a remarkably effective collection. A graceful Palm formed the centre, the edge of the circle was fringed with Maidenhair Ferns, Primulas of the verticillata type, Cyclamens, Lachenalias, &c., while the body of the group was composed of Azaleas, Rhododendrons, Spiræas, Ferns, Epacris, &c. The plants here were in fine condition, and the arrangement was first-rate. Mr. Buckmaster, gardener to Sir Henry Hussey Vivian, came second, the Azaleas and Orchids being exceedingly fine, as were many more of the plants, but they had evidently been arranged in a hurry, as they were too crowded; individually the specimens were of a high order. Mr. Harris, gardener to Mrs. Vivian, Singleton, was placed third with a fine group, which displayed more superior culture than taste in arrangement, as the plants here again were excellent and the blossom both rich and profuse, and altogether these three groups reflected much credit on those who cultivated the plants.

For the best collection of twelve cut flowers Mr. Harris was a good first, showing some superb heads of Rhododendrons, Orchids, and Roses. In the hand bouquets Mr. Harris was again deservedly successful, and Miss E. Barron of Sketty Nurseries won in the buttonhole bouquets with attractive brace. In the miscellaneous collection of plants Mr. Stafford, gardener to J. T. D. Llewelyn, Esq., was an easy first with a splendid collection, including Pelargoniums bearing trusses of prodigious size and wonderful colour, Auriculas nicely flowered, herbaceous Primulas, Pansies, &c., altogether an interesting and attractive collection; Mr. Harris was second with another good lot. In the nurserymen's section Captain Mansfield, St. Clear's, was first in the group class with small but excellent flowering and foliage plants; and Mr. Barron of Sketty was second with a first-rate selection of valuable Conifers and Evergreens. Cinerarias were dwarf and well bloomed, and Mr. Farrant, College Street, Swansea, and Captain Mansfield secured the leading prizes. In Azaleas Mr. Farrant and Mr. Speck, Llanelly, divided the honours with healthy finely bloomed plants. In Hyacinths and Tulips Mr. Barron was quite in advance of others and secured both firsts, Captain Mansfield and Mr. Speck following. The bridal bouquets were superb; indeed, we have never seen finer in South Wales. Mrs. Loadstone, a lady florist of Llanelly, was first with a massive, beautiful, and artistic arrangement, excellent; and Captain Mansfield was second with another of a less showy character. In buttonhole bouquets Mrs. Loadstone was a good first, Mr. Farrant being second; and in

wreaths or floral devices Captain Mansfield was first with a very elaborate wreath, Mr. Barron second with one remarkable for its simplicity and sweetness, and Mrs. Loadstone third with another slightly too heavy. In the miscellaneous class Mr. Farrant was first with a group of well-bloomed but small plants, while Mr. Barron was second with many fine plants, rather crowded.

Vegetables were well shown by Mr. Harris and Mr. George Nott. The amateurs were creditably represented by Mr. Morse, Sandore, Mr. Paddon, Mr. Hitchings, and Mr. Waters. Apart from the numerous groups entered for competition, the local nurserymen and florists exhibited large quantities of excellent plants and flowers for exhibition, and in this respect special mention deserves to be made of Mr. Barron of Sketty and Blackpill, Captain Mansfield, Mr. Farrant, Mrs. Loadstone, and Mr. Clare of Temple Street.

### NOTES FROM MY GARDEN IN 1885.—No 2.

#### ROSES.

ALTHOUGH I gave in last year's volume a survey of the Rose season in general, I did not especially allude to my own garden, and indeed had in view rather the Rose as an exhibition flower, and the character of the season as affecting the many shows held throughout the country, and therefore do not feel that I am quite travelling over the same ground in giving these notes of the Rose in my own limited space; and for the reasons I have already given they may be acceptable to some of the readers of the Journal.

I do not exhibit, and therefore do not grow for exhibition; but as I have to so frequently act in the capacity of judge I like to have under my own eye the leading varieties and the new ones as they appear, so that I may be familiar with them when they appear in the stands. I grow them in a separate part of my garden, so that no other flower interferes with them, and they probably receive much the same treatment as they would do were they grown for exhibition, save that I do not disbud so rigorously, nor do I grow maiden plants. Besides this I have a few Teas planted against the wall, so that my season is a tolerably prolonged one. I do not grow any under glass save one plant of *Maréchal Niel*, which I have at the back of my small annexe, where I grow a Vine. This plant is somewhat of a novel character. I had it three or four years ago from Mr. Priuce of Oxford, and it was grown in a large pot; the shoots were nailed up to the back of the house, and I expected at most to have got a couple of years out of it. However, it pushed its roots through the hole at the bottom of the pot and into the soil on which it stood. There it has remained, and made some very vigorous shoots, which, however, had to be cut back, as they would have interfered with the other plants in the house, and especially with the Vine. It has borne this treatment very well, as last spring I cut from it about 120 blooms, and it is now showing well for bloom and exhibiting no symptoms of decay, as it flowers and makes growth before the Vine begins to start. The latter does not interfere with it. The wood becomes well ripened. By the time that these were over the Teas and Noisettes on the wall began to develop their blooms. It is a great satisfaction to me that my grand plant of *Rêve d'Or* has so much recovered from what I feared was its *coup de grace* in 1880 and 1881. It has now gone up 12 or 14 feet and bloomed well, and as I have protected it this winter I hope it will do even better this year. Besides it I have in my house that very good climbing Rose Longworth Rambler, which is very hardy and very floriferous, and its colour gives it a great claim, being of a very bright red tint somewhat like *Reine Marie Henriette*, although a much thinner Rose than that variety, but more free-flowering. A plant of that on my gardener's cottage gave some very fine blooms. It is not a colour much beloved of ladies, but still useful. I have also *Madame Berard*, *Belle Lyonnaise*, and *Climbing Devoniensis*, which have all grown most vigorously. *Madame Berard* has too much of the loose growth of *Gloire de Dijon* to be quite what one wants. *Belle Lyonnaise* gave me a quantity of fine bloom, although displaying in most cases the one fault it has—viz., cleft blooms. *Climbing Devoniensis* was most satisfactory; the blooms of it were lovely, and were produced very freely.

I have on the wall *Madame Margottin*, *Perle de Lyon*, *Bouquet d'Or*, *William Allen Richardson*, *Comtesse de Nadailac*, *Madame Van Houtte*, *Madame Caroline Kuster*, *Catherine Mermet*, and *Ma Capucine*. These all flowered well, and especially *Nadailac*; indeed the flowers of this lovely variety develop with me some remarkable colouring, so much so that my friend Mr. Biron, no mean judge, told me he never sees it so well coloured elsewhere. I am afraid some of these will have to give way, as they are planted between the Peach trees, which are gradually usurping the space devoted to them. These few Tea Roses are very acceptable to me, as they give blooms before those in the open develop themselves. Teas are of course the first to come in there. I did not prune mine so hard as in the year before, and they did very well. They have, in fact, now quite filled up the beds, and as hard pruning implies more vigorous growth I avoided it mainly for that purpose. Amongst those Teas of more recent date which greatly pleased me were *Madame Watteville*, *Madame Cusin*, and the Hon. Edith Gifford. They are well known, and therefore there is no need of saying much about them. They all seem to be good growers, and, like most of their race, very free bloomers. *Madame Cusin* is quite as dark as I care to see.

The decision formed by the National Rose Society that Hybrid Teas are to be classed amongst and shown as Hybrid Perpetuals, is the only logical one that could be made, for as it is impossible to make a separate class for them, and they cannot be shown as pure Teas or Noisettes, they would be excluded altogether if this were not the decision. Take for example *Lady Mary Fitzwilliam*, what confusion has been made with it. Some assert that it is a Hybrid Tea, others that it has no Tea blood in it,

and as a consequence of this confusion a stand of Hybrid Perpetuals was disqualified because it contained it, while at another place it received the National Rose Society's medal as the best Hybrid Perpetual! It is a very beautiful Rose for those who can grow it, but the general verdict upon it is that it is a most difficult Rose, never making much wood, and delicate in habit; in truth there are not many of these so-called Hybrid Teas that have found very extended favour, and Roses have been so intermixed by hybridisation, whether natural or artificial, that it is exceedingly difficult to say what blood they do or do not contain. One of the foreign growers is, I see, now crossing some of the single Roses with double varieties, and professes to have obtained some varieties that are to be worth growing. *Nous verrons*. We have to take a great pinch of salt when we try to digest many of these high-flown descriptions. As I did not "go in" for exhibiting, I did not last year prune so hard as the year before, wishing to obtain larger plants and more bloom. There is little doubt, I think, that hard pruning will be the rule this season, as Jack Frost must have laid his hand very heavily on the young wood, especially where it is very "lisky," and it is of no use leaving any wood where the pith is discoloured. My plants were well protected with litter, but there was little need for protection last season. When the plants were pruned in the spring the long litter was all raked off, made up into a heap, and made a capital bed for growing Vegetable Marrows; the short manure was all gently forked in. As I have frequently said, my soil is not very good for Roses, but it has been much improved by the addition of some clayey loam. The greater portion of my plants are from three to four years old, but, as I cannot enlarge my borders, some are taken out every year to make way for some of the newer varieties. Of these I had several last year, although nothing was very remarkable amongst them. Mr. Laxton's two seedlings, Bedford Belle and Gipsy, were not sufficiently strong to enable me to judge whether they will be of value as exhibition or garden Roses. Lord Frederick Cavendish is a very brilliant coloured Rose, and bears out the good character it acquired on its first introduction. Ulrich Brunner was very fine with me, as it was everywhere last season, while the fine dry season suited Merveille de Lyon and Violette Bouyer to a nicety, and we had many fine blooms of them. Grace Darling I had not sufficiently strong plants of to judge as to its qualities, for where the plants were either small or had to be lifted, the long dry time was very much against their growing much. It seems, however, to be a very promising Tea. Of Madame Cusin and Madame de Watteville I have already alluded to. There is another which I had, but not before it was too late to judge of it, the new American Rose Sunset, but of which I am inclined to form a high opinion. It has well been described as a very double Madame Falcot, and is a sport from that grand yellow Rose Etoile de Lyon, than which we have no finer yellow garden Rose. I cannot say that as yet the descriptions of Gloire Lyonnaise have been in the faintest degree approached in reality; there has not been in any bloom I have had of it, or any that I have seen, but the very faintest *souppçon* of yellow in it.

It has been often said that however beautiful the Rose may be, its season is a short-lived one. I cannot and do not think this is a correct statement. It is no doubt true that, like most flowers, it has its special season when it is in the height of its glory, and from the beginning of June to the end of July, according to the locality, the "feast of Roses" is held, when the rosery is all aglow with beauty and delightful in its fragrance; but as I have shown, there is to those even whose space is limited an opportunity of antedating that period by the wall Roses and Teas, and although the three weeks in which the rosery is in its full beauty seems but a short time, we must remember that for a long time afterwards Roses are to be obtained in great beauty. The Hybrid Perpetuals throw out a second stock of young shoots, and these have given me some nice blooms on through July and August, the greater proportion not being equal it is true to the first blooms, but still fresh and fragrant; while the Teas afford an almost never-ending supply of beautiful and fragrant blooms, and where these are grown in any quantity they are to be had up even to the dark days of November. I had them myself in my own small garden, and so I am sure that where they are grown in larger numbers it can be easily done.

I have not as yet done much in the way of single Roses, but hope to try a few of them. One, indeed, I had in my small rockery, Rosa pyrenaica; but it became such a nuisance that I had to take up some yards of the rockwork and grub it all out—at least, I hope I have done so. But it is a most persistent interloper, getting in under the stones and throwing up its suckers in the midst of some of your most dearly valued Alpine gems. Rosa rugosa and rugosa alba I have grown, but not as well as I could have wished, for they are very ornamental in foliage, flower, and berry. I have no doubt that the excellent paper of Mr. Girdlestone, and the attention which has been drawn by him and others to the "species" of Roses, will bear good fruit in the future.

There is one misfortune which I have to suffer each year, as far as my Rose garden is concerned—viz., that I am so much away from it in the blooming season. The attendance "on circuit" necessitates this, and I often grieve over it. However, if I do not enjoy my own Roses so much as I could wish I have the pleasure of seeing better blooms of other growers. The time will doubtless come when I shall no longer be able to gad about as I now do, and then I may be perhaps able more thoroughly to enjoy my own garden.—D., Deal.

#### HYBRID ORCHIDS.

A FEW additional notes respecting the list of hybrid Orchids given last week may be useful.

It will be seen from this list that while hybridisers have been very

successful in some genera they have not obtained many results in several others, and in a few they have hitherto failed to secure any hybrids. Thus of *Aerides*, *Anæctochilus*, *Goodyera*, *Phalænopsis*, and *Taunia* one hybrid each has been raised. Of *Chysis* and *Phajus* two each, of *Masdevallia* and *Zygopetalum* three each, of *Lælia* seven, *Dendrobium* and *Calanthe* nine each, *Cattleya* twenty-four, and *Cypripedium* fifty-three, nearly half the total number having been obtained in the last-named genus. In the case of the *Cattleyas* Mr. H. J. Veitch has observed that the "members of the labiata group and also the Brazilian species with two-leaved stems, as *C. intermedia*, *C. Acklandiae*, &c., cross freely with each other and the Brazilian *Lælias*: but neither the *Cattleyas* nor the Brazilian *Lælias* will cross freely with the Mexican *Lælias*, such as *albida*, *autumnalis*, *majalis*, and *acuminata*, except *L. anceps*." From the same authority we learn that the East Indian *Cypripediums*, though crossing readily with each other, do not cross so freely with the South American *Selenipediums*; and though plants have been raised from crosses between these two sections, they have not flowered yet. No one appears to have succeeded in flowering an artificially raised hybrid *Odontoglossum* up to the present time, although so many are regarded as probable natural hybrids. Mr. Cookson obtained some seedling *Odontoglossums* from a cross between *O. gloriosum* or *O. Uro-Skinneri* and *O. crispum*, but they subsequently died. The late Mr. Spyers, when gardener to Sir Trevor Lawrence, obtained seed from crosses between *O. vexillarium* and other species, but he informed me that he could obtain no seed from crosses between *O. vexillarium* and the *Miltonias*; and I believe it was from the same source that Mr. Bentham obtained the statement he inserted in the "Genera Plantarum" to that effect, and to which Mr. H. J. Veitch objected as contrary to their experience. He has found that by crossing *O. vexillarium* and *Miltonia spectabilis* seed was produced, though it could not be secured from crosses with any other *Odontoglossum*. It does not appear, however, that seedlings have been raised in any case.

As examples of bigeneric hybrids we have crosses between *Anæctochilus* and *Goodyera* and *vice versa*, *Lælia* and *Cattleya*, *Phajus* and *Calanthe*, *Calanthe* and *Limatodes* and the reverse, though in the last instance *Limatodes* is now referred to the genus *Calanthe*, and *Cattleyas* and *Lælias* are very closely allied. Many strange crosses have been made in Messrs. Veitch's nursery. Thus plants have been raised, but not flowered, from crosses between *Cattleya Trianae* and *Syphonitis grandiflora*, *C. Trianae* and *Brassavola Digbyana*, and *C. intermedia* and *Syphonitis grandiflora*. Capsules of apparently good seed have been had from crosses between *Acanthophippium Curtisi* and *Chysis bracteescens*, *Bletia hyacinthina* and *Calanthe Masuca*, *Chysis aurea* and *Zygopetalum Sedeni*, *Odontoglossum bictonense* and *Z. maxillare*, *Z. Mackayi* and *Lycaste Skinneri*. Abundance of seed has also been secured by crossing *Z. Mackayi* with *Odontoglossums* and other genera, but the seedlings have been invariably proved to be *Z. Mackayi*.

The principal hybrids mentioned in the list under Mr. Seden's were raised by the following orchidists:—

*Anguloa media*, by J. C. Bowring, Esq.; *Calanthe bella*, though sent out by Messrs. Veitch & Sons, was not raised in their nursery; *Calanthe Alexanderi* and *Cooksoni*, by N. C. Cookson, Esq., Wylam-on-Tyne; *Calanthe porphyrea*, by Sir Trevor Lawrence, Bart., M.P.; *Calanthe sandhurstiana*, by Mr. P. H. Gosse, Sandhurst, Torquay; *Cattleya calummata*, by Mr. Alfred Bleu, Paris; *C. Mitcheli*, by Mr. Mitchell, gardener to Dr. R. F. Ainsworth; *C. veriflora*, origin unknown, bought as a seedling at Stevens' Rooms by Sir Trevor Lawrence; *Cypripedium Ashburtoniae* and *Crossianum*, by Mr. Cross, gardener to Lady Ashburton, Melchet Court, Romsay; *C. Io*, by N. C. Cookson, Esq.; *C. Leeannum*, by Sir Trevor Lawrence; *C. chloroneurum*, *C. meirax*, *C. melanophthalmum*, *C. politum*, and *C. Williamsianum*, by R. Warner, Esq., Chelmsford; *C. conchiferum*, *C. gemmiferum*, and *C. stenophyllum*, by J. C. Bowring, Esq.; *C. Swannianum*, by Mr. W. Swan; *C. Laforcadei*, by M. Bauer, Paris; *C. Sallieri*, by M. Godefroy-Lebeuf [M. Bergman, in "Revue Horticole," October, 1885]; *C. Seedling No. 1*, M. Bleu, Paris; *Dendrobium Ainsworthi*, by Dr. R. F. Ainsworth; *D. Leachianum*, by Mr. W. Swan, when gardener to W. Leach, Esq., Fallowfield, Manchester; *Masdevallia Fraseri*, by Mr. Fraser, Dornoch, Aberdeen; *Thunia Veitchiana* or *Wrigleyana*, by Mr. George Toll, Manchester; *Zygopetalum Clavi*, by Colonel Clay, Birkenhead.

The natural hybrids are mostly introduced forms of exotic Orchids, which are found to be so clearly intermediate between the species named as parents, that they are regarded as the probable result of hybridisation effected by insect agency. Some European forms are, however, included, as in the genus *Coeloglossum*, *Gymnadenia*, *Nigritella*, and *Orchis*, which have been noted and described by continental botanists.—L. C.

#### THE PRIMULAS.

(Continued from page 292.)

*P. TYROLENSIS*, Schott.—This is a fairly common plant in English gardens now, although it rarely flowers so well as it does in its native habitats. On the rockery, even where fully exposed, it grows very freely, forming loose tufts, the stems being apt to become leggy unless pegged down or surrounded with stone debris. It is distinct from all the other Primroses, and easily recognised, from one of the bracts at the base of the flower attaining an uncommonly large size. With us it grows from 3 to 6 inches in height; the leaves ovate or elliptic, hairy, but showing more distinctly at the margins, which are finely serrated

The leaves are prominently veined on both sides; calyx campanulate, the divisions rounded at the apex, pedicels very short or none, at the base of which are two or three narrow linear bracts, the large one being like an ordinary leaf, and about as broad. The flowers are an inch or so in diameter, purplish rose, with a white eye, generally only one on each scape, opening April and May. Exposed situations, rather dry in rich soil, with plenty of granite sand. Native of the Tyrol. Syn., *Allionii*, *Auct.*

*P. VENUSTA*, *Host.*—A hybrid between *P. Auricula* and *P. carniolica*, *Schott.* It is one of the most handsome of the Primulas when well grown, its large clear rosy flowers showing well above the foliage. In the open border or on the rockery it seems to grow as freely as the common Alpine Auriculas, which it much resembles in habit. It forms stiff rosettes of blunt oval leaves, irregularly serrated or notched at the margins. Flowers large, from two to five on a scape, bright rose with white eye. It grows best, partly shaded from the mid-day sun, in rich soil, to which has been added limestone grit. It flowers from the middle or end of March to May. Syn., *Freyeri*, *Hoppe.*

*P. VERTICILLATA*, *Forsk.*, is said not to be in cultivation. The plant cultivated under that name being *P. Boveana*, *Dene.*

*P. VISCOSA*, *Vill.*—Under this Mr. Baker has placed *P. villosa*, *Wulf.*, and together with their many varieties they seem to give more trouble to botanists than all the other Primroses in cultivation. On the continent generally *P. villosa* is held to be a distinct species, and it is said that the true *villosa* is not found in the Central Alps, but only met with in Carinthia and the districts where crystalline limestone predominates. The flowers, it is also said, are twice the size of *P. viscosa*, deep purple rose, with a white ring round the centre, and having an orange yellow eye. Be all this as it may, in our opinion *P. villosa* is not more distinct from *P. viscosa* than the latter is from *latifolia*, *pedemontana*, *decora*, and a host of others generally included under *viscosa*, and which name being the oldest has preference over the other. Typical *P. viscosa*, as we know it, has shiny glutinous or viscous leaves, deeply serrated, as well as glandular at the margins. The flowers are numerous in a head, small, purplish rose-coloured, and having no distinct ring round the eye. This viscosness of the leaves wears off as we examine the forms in the direction of *P. Simsii*, *ciliata*, &c., varying also in size and shape until we come to the large leaved *latifolia*, with almost every variation in purple of the flowers to the pure white of the handsome *nivalis*. They will thrive in almost any position on the rockery, and may do well in the ordinary border even, with the aid of a few stones round the stems. The finest of the type we have ever seen was grown on a small rockery behind a house facing north-west, apparently quite unmindful of the soot, &c., which had collected largely on its viscous leaves. They flower April and May. Natives of the Alps, Pyrenees, &c. A few of the principal varieties are *ciliata*, *Schrank*; *commutata*, *Schott*; *hirsuta*, *All.*; *latifolia*, *Lap.*; *pedemontana*, *Thom.*; and *nivalis*, *Hort.*

*P. VULGARIS*, *Huds.*—The common Primrose, though possessing none of the gaudy colours of most of the South European species, has a beauty far preferable to theirs—sufficiently so, indeed, to merit a first place in our collections—the more so now, as it is fast disappearing from the spots where a few years ago it was so plentiful. Like many of our old garden or native flowers, its beauties have not been overlooked by the poets—Wordsworth's "Primrose by a river brim," and again by Goldsmith in "The Deserted Village"—

"Her modest looks the cottage might adorn,  
Sweet as the Primrose peeps beneath the Thorn."

In cultivation the Primrose grows best in sheltered nooks or near bushes where it may be protected, and where it opens its flowers about the end of March. There are many coloured varieties in cultivation at the present time, one pure white, very handsome, and var. *Sibthorpii*, which answers to the old var. *rubra*. It is increased from seed or division of the roots.

The species, varieties, and hybrid Primulas enumerated in the pages of this Journal, commencing page 269, vol. ix. of the third series, comprise as nearly as possible all those in cultivation at the present time. Unfortunately, the series is not so complete as it might be, owing partly to want of material, as well as the material at hand not always being thoroughly reliable. No two hybrids are said to be alike in all respects, and this is borne out more strikingly in the case of Primulas than in any other genus with which I am acquainted; and, like the *Narcissi* previous to the Conference two years ago, no two growers have the same forms under exactly the same names. This state of affairs will no doubt be largely remedied at the Conference, where a comparison of plants with reliable figures and drawings will help to show the advantages to be derived from meetings of

this kind. Primulas, though not generally fastidious plants, require much attention to do them well, and in gardens where suitable, will need special provision in the shape of a rockery or prepared raised bed. It will be found more satisfactory to divide them into three groups—1, Semi-aquatic, those that grow best in damp shady places; for example, *P. rosea*, which in its native habitat is said to be found with its roots always some distance in water. 2, Those that do well in the ordinary mixed border; such as *japonica*, which does not only stand the winters, however severe, but seeds freely: *cortusoides* and others to be enumerated may also be grown in this way. 3, Failing a suitable rockery, those that can only be grown satisfactory in pots, such as *Allionii*, *biflora*, and many other small kinds. In the first or semi-aquatic group, *rosea*, which was described at page 275 of vol. x., together with its variety *grandiflora* (sent out first, we believe, by Max Leichtlin, Baden-Baden), *P. involucrata* and *Munroi*, *P. Parryi*, &c. are amongst the best that may be treated in the dampest part of the bed; while on raised mounds, *farinosa*, *scotica*, *Warei*, *sibirica*, *sikkimensis*, and most of the other Himalayan Primroses may be grown. In sheltered and shady nooks, which need not be particularly damp, *capitata*, *denticulata*, *Stuartii*, *obtusifolia*, and others will do well. In the ordinary border the second group, comprising the *Polyanthus* and, indeed, all the *Primulastrum* section, together with the Alpine Auriculas *Palinuri*, *Peyritshii*, *japonica*, *cortusoides* and its varieties, many of the *viscosa* forms, and on little raised mounds *integrifolia*, *marginata*, &c., will be found to do well and flower almost as profusely as if grown on rockeries. Some of the varieties are far superior garden plants to the types. In the third group, as above stated, unless a special rockery be available, it will be much better to grow them in pots, plunging them in the open ground in sand, or, as is often adopted on the Continent, simply standing the pots on sand beds, attending well to watering, and only covering the plants with lights in case of heavy rains or frosts during the winter season. With the latter method of growing them in pots they are always under control, and individual plants may receive different treatment without disturbing the roots, which most of the smaller species quickly resent. Under this group may be included *minima*, *biflora*, *Berninae*, *Allionii*, *tyrolensis*, *Flörkeana*; while *floribunda*, *Boveana*, *obconica*, &c., do much better with greenhouse treatment—indeed, we question much if it is possible to grow them successfully in the open air, as they are destroyed during winter, not so much from cold as from damp and fogs. A full list of the species and varieties will conclude our series.

—D.

#### THE LATE MR. TURNBULL, BOTHWELL CASTLE GARDENS.

THE death of Mr. Turnbull at the Garden House, Bothwell Castle, on the 18th inst., has removed a well known figure from the horticultural world of Scotland. Mr. Turnbull was born at Leger Wood, Berwickshire, January 18th, 1804, and served his apprenticeship at the Haining, near Selkirk. In the year 1821 he removed to the Duke of Buccleuch's gardens at Dalkeith, then under the able management of Mr. McDonald, who soon discovered that in young Andrew Turnbull he had an assistant of rare value. He soon promoted him to be foreman in the plant department, and in due course to be general foreman, and the writer of this obituary notice had it from Mr. McDonald's own lips, that of the hundreds of such men that had passed under his charge, he never had a better than Andrew Turnbull. His expression was, "Whatever you placed under Andrew's charge was sure to be well attended to." When Lord Archibald Douglas succeeded his father in the Douglas estates, he applied to Mr. McDonald for a gardener for Bothwell Castle, and he recommended young Turnbull, who entered on his duties in 1828, and no man ever more faithfully discharged them than he did, gaining the high esteem and friendship of six successive employers, including the present Earl of Home. All these noblemen and noble ladies, including the present Earl, were exceptionally kind to everyone employed on their estate, and Mr. Turnbull, while exacting justice for the employer, was an excellent exponent of the latter's kind feeling for the employed, thus retaining the respect and esteem of both.

When Mr. Turnbull entered on his duties at Bothwell Castle it was then the leading garden in the west of Scotland; there were then few great gardens as we know them now. Bothwell Castle was, and is now more than ever, surrounded by mining and manufactures, and its noble proprietors in consequence did not add to the glass structures, as in other circumstances they would have done, the result being that in that respect it fell behind many gardens of the present day; but for a well managed kitchen garden, for its collection of hardy herbaceous plants, and for its Heaths, it had few equals. It is generally known that Mr. Turnbull raised more fine seedling Heaths than any man, and that of these plants he was a most successful cultivator.

When Mr. Turnbull began his career at Bothwell Castle he first directed his attention to improving the herbaceous *Calceolaria* with eminent success. His Lord Douglas, a splendid large purple flower now lost, has never had an

equal of its colour. When the writer had the good fortune to enter under Mr. Turnbull in 1832 he was just beginning to raise seedling Heaths, and he has continued to do this up to a very recent date. When I heard from him a few weeks ago, he remarked that he had taken advantage of the bad weather to get most of his Heaths shifted and staked. I replied a week ago sending him some blooms of a new Orchid he was anxious to see, but never heard from him again, thus closing a correspondence that for forty-nine years has been uninterrupted.

Mr. Turnbull was one of the first cultivators of Orchids in Britain, and though his facilities were small he grew some remarkable specimens, one of which is at this moment the finest probably in Europe—I refer to his grand plant of the autumn-flowering *Cattleya labiata*, which for forty years has produced from eight to twelve spikes of bloom annually.

For a number of years Mr. Turnbull has had the charge of the whole grounds, including the farm at Bothwell Castle, which he has managed with that upright honest fidelity to his employer that was a striking characteristic of his nature. If he abhorred anything it was double dealing of any description. His was a soul of transparent honesty. Mr. Turnbull was never married, a most excellent sister kept his house till her death some twelve years ago. He had saved a little money, which he lost in the City of Glasgow Bank when it failed. The writer went to see him on that sad occasion, and found him as brisk and cheery as ever, and as ready with a joke. No man had a keener appreciation of a well-told amusing story, or could laugh more heartily at one. His word was his bond in all things, and take him all-in-all he has left few his equals. His remains are interred in Bothwell Churchyard beside those of his sister and brother.—W. T.

## PLANT, SHRUBBERY, AND WOODLAND BORDERS.

ADJACENT to most gardens are semi-wild places—a rank mass of struggling, entangled vegetation. Shrubs smothered with trees allowed to grow and remain much too close for even their own development, the commonest and coarser having obtained the mastery. Most places of this kind exhibit unmistakeable evidence of timely thinning and judicious attention to pruning having been neglected; but “it is never too late to mend,” only it is commenced very often when many of the choicer trees and shrubs are irretrievably spoiled. Much, however, may be done by a judicious thinning to let in light and afford headway to the shrubs, and some of the latter cleared off along with the rubbish to make room for plants that grow in such situations naturally, and look better than under the restraints of cultivation. Most of our shrubbery borders and woodlands would be the better for a weeding alike of tree, shrub, and bush, as well as of the coarser vegetation. Rubbish cleared away would soon make space for many plants which, not perhaps appropriate in dressed grounds, are quite at home in woodland glades and nooks and corners of shrubland walks, but even clearances of this kind must be done with judgment, as the plants to be introduced must have shelter. Regard will also have to be had to the soil and location, which is all the better, as we get variety in proportion to the change of soil or its location in respect of sun and shade, or presence of moisture in sloping banks or hollows or well-drained knolls that afford scope for the accommodating of various plants.

Of plants that have a peculiar appropriateness are Primroses. No wood or shady spot is complete without them, and as we can have them in varied shades of colour the ground may be set all ablaze with their charm and beauty. The Primrose delights in yellow loam inclined to be heavy and moist rather than dry and light, and with shade of deciduous trees not forming too dense a canopy in summer as to obliterate the growth of grass or weeds, and not utterly deprive it of moisture, they hold their own, flourishing vigorously and blooming profusely. Polyanthus show off well in association with Primroses, and grow and thrive equally well or better. In nature they grow freely enough and spread rapidly by self-sown seed, their seeds germinating most readily immediately they are ripe and gathered when the capsules are bursting; but time may be taken by the forelock to procure some seed and sow at once, and whilst about it, it is just as well to get some Alpine *Auricula* seed and sow it, as these harmonise well with Primroses and Polyanthus. The seed may be sown on a north border, and preferably in a cold frame in fine soil, as the frame insures uniformity of moisture, and shade can readily be given, which if closed are certain to bring the seedlings quickly. When large enough to handle harden them and prick them off about 3 inches apart on the north border, and in spells of dry weather water will not be lost upon them, weeds being removed, as the stronger the plants are the finer they are likely to flower the spring following.

Then there are Violets, which everybody likes, and though they come freely enough from seed it is a method not much resorted to, though it may be practised by sowing the seed in a similar manner to Primroses, and treating the seedlings in a like manner, only the plants will need more room, as they develop more foliage than the slower-growing seedling Primroses. Those who have beds of Violets will have no difficulty in getting the plants, only leave the beds that

would under ordinary conditions be broken up alone until autumn when they will have rooted runners in abundance, that may be taken up, divided, and planted without needing any attention afterwards. Everybody seems to give themselves as much trouble as possible with Violets, planting them in spring in rich soil and open spots to cause as much trouble in watering and in getting as luxuriant a crop of leaves as possible, without any idea of this being just the way not to get flowers. Plant Violets wild in autumn, and they will have Nature's moistening through the winter in quantity, sufficient to insure their establishment. Violets with blooms like Pansies are inappropriate in the shrubbery and woodland; besides, they do not get large there. The sorts at home there are the Russian, Crimean, London, and I do not know how many other names it passes under, but is certainly *Viola odorata suavis*, with variation due to soil and location. The single pink variety (*Viola odoratissima rubra*) is another that does well; and then there is the common Sweet Violet, with its grey and white forms that are not infrequent in gardens under other names than the right one, and Lee's *argenteaeflora* is in its right place there if anywhere. It grows so freely and flowers so profusely as to fill the air with perfume. Lee's *odoratissima* also does well, and has a fitting companion in White Czar.

Myosotis or Forget-me-nots are great favourites, especially the lovely *M. dissitiflora*, its pinky blue flowers always attracting admiration. It likes moist places, and does well in partial shade, but cannot bear stagnant water, thriving best where the soil is kept moist by water percolating through it, and near running water. It does best in sheltered positions, as cold cutting north-easters and spring frosts mar its beauty unless so located as to be tempered before reaching the Myosotis. *M. sylvestris* will, of course, succeed in denser gloom, but it is best seen only in partial shade. Seed sown now will give fine plants for putting out in autumn, and once established they produce seed freely.

Columbines, of which there is now combinations to please all tastes, from lavender through blue to mauve, rose-pink to scarlet, yellow to orange; even those that like no colour at all have it in white, and the flower lover has the most striking and effective contrasts in the same flower. Douglas's hybrids are beautiful, and the old sorts with the fresh blood in them are simply captivating. Seed sown now will give fine plants for putting out in autumn. They soon get naturalised by self-sown seeds, and make charming groups. They like good soil and not dense shade, but there is plenty of bare spots that will suit them.

Mimuluses are fine for moist places. The spotted, though usually seen in greenhouses, are hardy where they get Nature's leafy mulching, *M. cardinalis* and *M. cupreus* making quite a display. The indispensable Musk never comes amiss, especially as a surprise in woods. These may be raised in cold frames, pricked outdoors on a shady border, and put out in autumn.—G. ABBEY.

(To be continued.)

## CINERARIAS AND THEIR CULTURE.

(Continued from page 299.)

### POTTING THE PLANTS.

ONE of the most important points to be observed in the culture of Cinerarias is to always pot them before they experience the slightest check till they are placed in their largest pots, for if once they become stunted they never grow freely afterwards. We always like to give them small shifts, as there is less chance of the soil getting sour before the roots have permeated it. From the 60-pots ours are shifted into 5-inch pots, then into 7-inch pots, and as soon as ready transferred to their largest pots (9 or 10 inches in diameter), which we find large enough for all purposes. It will therefore readily be seen it is useless to state the week or month in which they should be potted into a certain sized pot; that will depend upon the progress they make. Let the cultivator be guided by the state of the plants. If on turning them out of the pots numbers of roots are found to have reached the sides of the pots, that is just the stage at which they require shifting; and at each successive potting the soil is made a little firmer than at the last, and when the plants are placed in their largest pots it is made decidedly firm.

### THE BEST SOIL.

Good turfy loam that has been stacked in a heap for twelve months is an essential ingredient in preparing the soil; and the manure and leaf soil used should be perfectly sweet and free from all insects. A small white grub sometimes found in leaf soil works sad havoc among the roots of plants. The best manure we find for the purpose is well decayed hotbed manure. If this is exposed to the sun before using, so as to allow it to be rubbed through the half-inch sieve, it will form an excellent material for mixing with the loam. The compost used for potting in the earlier stages of growth should be rather lighter than that used at the final potting. When shifting into 5-inch pots, three parts loam, two of the leaf soil, and one part manure, with a good sprinkling of charcoal broken very small, some road sand, and a little soot will form a very suitable compost, gradually increasing the proportion of loam till the final potting, when three parts loam, one of manure, and one part leaf soil

with the other ingredients as before, should form the mixture. The whole of the soil is passed through the half-inch sieve for the 5-inch pots, after that only the manure and leaf soil is sifted.

#### SUMMER TREATMENT.

About the beginning of June the plants should be transferred from the Melon pit to a cold pit or frame, where they can be kept close to the glass. If a stage of boards was to be erected for that purpose place a layer of coal ashes on the boards before setting the plants thereon, as the ashes will retain the moisture from the syringing and watering, and consequently keep the atmosphere about the plants in a humid state, so necessary to insure perfect health. Throughout the summer months the best aspect for the frame in which they are grown is due north, but failing that the foot of a west wall will do, only then the plants will require more shade. When the former aspect can be obtained they will require but little shade, none being given when the sun is high and strikes directly on the plants, and it should be removed early in the afternoon, according to the weather. On bright days the plants should be slightly syringed between four and five in the afternoon, and about half an inch of ventilation left on the back of the frame, or more if the weather is still bright and warm. I was once very much puzzled to know why so many plants under my charge went off in a way peculiar to *Cinerarias* during the summer months; the more so because I knew they were not over-watered, neither were the plants potted deeply, and on turning them out of the pots the roots appeared quite healthy, although the plants were drooping beyond recovery. On examination I found in every case they succumbed at the collar, and when the stem was broken at that point it was found black in the centre. After much consideration I thought it must be caused by closing the frame at syringing time, as I had been in the habit of doing up till that time to push the plants on, being opened again in the evening. I then regularly left air on, as described above, at syringing time, and since then have had no trouble with the plants. During the fine dewy nights of July and August the lights should be taken off and replaced early the next morning. This helps greatly to keep the plants vigorous and sturdy. At the beginning of September they should be transferred to a pit facing the south, and should the weather be bright they will require shading with some light material for a time; but all shading should now be gradually dispensed with till the plants are able to bear full sunshine without flagging to any great extent, and in order to assist them to do that damp between the plants with a syringe morning and afternoon whenever the weather is very bright. Abundance of air should now be given on all favourable occasions, but avoid the cutting winds which are often prevalent at this season of the year.

#### TREATMENT FROM OCTOBER TILL APRIL.

There can be but little doubt that the best structures for wintering the plants in are span-roofed houses or pits furnished with hot-water pipes, which would only require to be heated sufficiently to keep out the frost and expel damp. But it is not everyone that is so fortunate as to be able to devote such structures to *Cinerarias*. It is, therefore, convenient to know they may be kept fairly well in well-built pits, but great attention is necessary to keep the damp and frost from injuring them. To guard against the former give the plants plenty of room for the air to circulate freely among them; be very careful not to give too much water at the roots, and ventilate on all possible occasions consistent with their well being in other respects. To keep out frost plenty of covering material must be placed over every part of the pit in severe weather, with mats and shutters over the lights, and a good covering of fern around the sides and on the shutters the plants will be safe from 20° or 30° of frost. About the end of December when the late Grapes have been cut and the houses cleaned these structures make capital quarters for them while they are kept cool, and as they come into flower can be removed to the greenhouse or conservatory. During the flowering period, if placed in large houses with plate glass roofs, they will require no shade, but when kept in houses with ordinary glass roofs, especially if the houses are small, a light shading will be necessary during very bright weather to prolong their season of beauty, as the weather we often experience in March is very bright and trying and disresses the plants a great deal if they are not shaded. We are seldom troubled with green fly till the plants flower, and on the first appearance of the insect the house is fumigated lightly on two successive nights and repeated again when required.

#### WATERING.

Any remarks upon the culture of the *Cineraria* would be singularly incomplete if they did not contain a few hints concerning this important operation, which is one of the greatest factors in bringing success or failure. Throughout the whole of their existence they require the exercise of great care and judgment in watering. There are times when the plants are liable to be permanently injured by having too little water, and at other times one dose too much would be fatal. When grown in the positions and given the treatment indicated above comparatively little water is required during the summer months, for the obvious reason that if the plants are shifted as soon as the roots reach the sides of the pots they are continually having fresh food supplied before the bulk of the soil is permeated by a network of active roots, and consequently do not absorb the moisture from the soil very quickly; they should, therefore, not have water given until the pots give a sharp sound when rapped and then be watered thoroughly. If kept in pits during the dull days of autumn very little water will be required, but as the days gradually lengthen the sun becomes more powerful and the soil in the pots is filled with roots, supplies will be required much more frequently, and neglect in this matter is

sure to tell the tale, though not always at the time. I have known plants completely collapse at this stage, which to the casual observer appeared to be suffering from the effects of too much water, the soil being very sodden when the plant first showed signs of distress, but which was really brought about in the first place by their once getting thoroughly dry. Many of the young fleshy roots then died. The plant was watered two or three times over with the result that the soil was completely saturated, and as many of the roots were already dead, and those left not in the best condition to perform their proper functions, so that instead of the moisture being drawn out quickly, as would be the case if the roots were active and healthy, remained saturated for a long time, and causes the plant to go off at the collar. When this occurs, if the stem is cut through, it will always be found black in the centre just above the soil. We give no liquid manure water till after the final potting; and when roots are plentiful then it is given at each alternate watering for a time afterwards every time the plants are watered till they come into flower, then it is discontinued and clear water given. Drainings from the manure heap, or that made from cowdung, are both excellent, but should be used in a greatly diluted state; and if soft water is given once a week the beneficial effects will soon be apparent by the rich green colour of the leaves.—H. DUNKIN, *Longford Castle Gardens*.

P.S.—A printer's error occurred in my article last week. The sentence should read, "Take great care not to bury (not wring) the collars of the young plants."—H. D.

#### EUPHORBIA JACQUINIÆFLORA.

At this season of the year this lovely stove plant may be readily propagated. This *Euphorbia* is reputedly a short-lived plant, which I consider due in a great measure to overwatering it at the roots and to general injudicious management, especially when planted out. It makes but few roots and requires but little room, and is always safest when the soil is kept rather dry. A stove temperature is required at all times, and a mixture of equal parts of peat and loam, with abundance of sand or very sandy peat; liquid manure or manures of any description I seldom use in its cultivation, and I have been successful in propagating and growing it.

To produce it in quantity I select a dozen plants which have been flowering during the winter in 48-sized pots; and turning them out of pots plant them thickly at one end of the stove where there is a temperature of from 65° to 75° maintained. Here they soon begin to push forth new growths from the uppermost parts of the old wood; these are the best for propagating purposes, securing them when about 3 inches long. To insure success with the cuttings they must be detached with a heel from the old plant, without this the cuttings and labour are lost. Prior to taking the cuttings the pots should be in readiness to receive them, and not more should be severed from the old plant at any one time than may be inserted and covered before they droop, which they do in a comparatively short time, consequent upon the milky sap which exudes from the base of the cuttings. This bleeding may be reduced to a minimum if the cuttings as soon as detached are thrust into some very dry silver sand. I lay considerable stress on keeping the cuttings quite fresh and plump and not allowing them to suffer in the smallest degree, and indeed it is to this I attribute my success, since experience has clearly shown that those cuttings which have once been allowed to droop do not readily recover.

Insert the cuttings in sandy peat, surfaced with about half an inch of dry silver sand, which will follow the dibble into the hole, and allow the cutting to rest upon it. Plunge the pots in a bottom heat of 75° to 85°, and cover tightly with a bellglass. I employ 48-sized pots for the cuttings on account of the difficulty experienced in getting bellglasses to fit certain pots, and by plunging these in 7-inch pots with cocoanut fibre, and placing the glasses on, they are rendered comparatively airtight. Give a thorough watering at the time of inserting the cuttings, and take care that the sun does not reach them. In this bottom heat they will emit roots in two or three weeks, when they may be removed from the pots in which they were plunged, and the glasses removed also, placing them for a few days in a shaded part of the house. At this stage it should be decided for what purpose they are destined. If required for the production of lengthened racemes of flowers they must not be stopped at all, but grown on liberally and kept near the glass; if smaller racemes are likely to be more in demand they may be stopped once or twice, removing only the tip of the shoot, and thus secure as many breaks as possible on the stem. This, perhaps, is best done when the plants are potted singly and have made fresh roots.

In potting press the soil firmly about them, and remember that a free drainage is essential. There is really no particular time of the year to propagate this lovely stove Spurge, for it will root any time from January to midsummer, or longer if cuttings are obtainable. The advantage of continuing their propagation to a late date is that various sizes of plants which may be used in a variety of ways may be obtained. The latest batch will do capitally for 5-inch pots, disposing them among foliage and other flowering plants in the warm conservatory or stove; the earlier batches should have more room, receiving their final shift about the middle or end of August into 6-inch pots, using equal parts of peat and loam, with plenty of sharp grit, and pot firmly.

During the winter months it is surprising what a quantity of its brilliant flowers it will yield, either in small compact bits so charmingly adapted for buttonhole flowers, or in long wreath-like arching racemes, which are so much valued for vases, for table decoration, or for ladies' head dress. When used thus it is one of those exceptional floral charms that furnishes foliage with flower, and needs nothing beyond its own leaves

to render it presentable. It is remarkable that this species is almost unique in point of usefulness and colour, *E. splendens* being the only near approach, and that not to be compared with the first-named. There are many other species included in the genus, several of which are true herbaceous perennials, as *E. pilosa* and *E. characias*, while *E. myrsinites* is alpine in character and of prostrate habit.—J. H. E.

### ROSE SHOW FIXTURES, 1886.

FOR the guidance of those Societies which have not as yet fixed the dates of their exhibitions I append the following list of Rose Shows arranged to be held during the coming season by the National Rose Society and Societies affiliated with it.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Diss Horticultural Society, at Diss, Tuesday, June 29th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Canterbury and Kent Rose Society, at Canterbury, Thursday, July 1st.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Thursday, July 8th.

Crystal Palace Rose Show, Saturday, July 3rd.

—EDWD. MAWLEY, *Rosebank, Berkhamstead.*

### HARDY FRUIT GARDEN.

Now is the critical time when blossom and foliage, especially of Peaches and Nectarines, must have our best care to protect it from cold. One of the best screens for wall trees we have seen this spring was a pair of curtains of thin sacking material, with brass rings running along an iron rod fastened to wooden blocks let into the top of the wall. Each curtain covered a little more space than half the tree, so that when drawn they overlapped, and they were then tied at the bottom to a wooden bar, to prevent them from being blown against the blossom. This was in the garden of an amateur who has only three Peach trees, which, owing to careful protection and skilful culture, never fail to afford full crops of fine fruit. Do not forget that the young foliage of Peaches and Nectarines suffers as much or more than the blossom from exposure to cold, cutting north-east winds, and if you allow the foliage to become seriously blistered, the growth is checked, the leaves fall prematurely, and it is impossible then that there can be a full healthy development of branch growth till midsummer. We cannot have fine fruit from weak immature wood growth, and when we protect the blossom we not only save the fruit crop of the current year, but we also do something for the crop of another season. The development of a crop of fruit is not the work of a season—of spring and summer—but of the whole year, and care or negligence, even in winter, and still more so in spring, leave an impress upon the trees which is visible the year round. If a gardener has proper means at his disposal for the culture of the trees under his care, he ought not to have any sickly or weak growth among his Peaches and Nectarines. We may go further, and declare positively that, under ordinary circumstances, he ought always to have a supply of Peaches from about the end of July till about the end of September.

This sweeping assertion is not made lightly, and is really the teaching of mature experience. Only a day or two before writing this note we saw a considerable number of Peaches and Nectarines in a large garden, to which protection had been given for the sake of the scanty blossom borne on a thin attenuated branch growth quite pitiful to behold. There clearly before our eyes was the impress of negligence or ignorance, for the whole of the trees should have been headed back near to the base of all the main branches in winter, no really robust fruiting wood being visible upon any of them. The necessity for such drastic treatment is an outcome of mismanagement; all Peach and Nectarine trees show signs of exhaustion sooner or later; the tissue of the branches hardens, the sap action becomes slower and slower, the annual branch growth shows a falling off in vigour. Head back such trees, renovate the soil, and you have growth of such extraordinary vigour that in a couple of years the wall space allotted to the tree is again clothed with healthy, vigorous, fruitful wood. This heading back is, under good management, so done that there is no serious deficiency in the annual supply of fruit, timely attention to the requirements of the trees enabling one to take one

or more trees year by year, for what may be termed hard pruning. We must take a high standard of excellence in our practice, and never rest satisfied with anything short of it.

The fruiting wood of a healthy Peach tree in full vigour is the size of an ordinary lead-pencil, and well set with triple buds. When there is a falling off in the size of the fruiting wood, fruit buds are frequently even more numerous, but they come singly, and there are often very few wood buds. This hint from exhausted nature is plain and unmistakable, and there must be no hesitation in acting upon it with promptitude and energy.

Repeatedly have we called attention to the great value of intersecting hedges in fruit gardens as a means of shelter at this season of the year. To plant trees with full exposure to the north-east is to court failure, and yet it is an easy matter to plant sheltering hedges among the trees and thick hells around them. Now is the time to gain valuable knowledge about this matter, cause and effect being before our eyes like an open page. The quick-growing *Thuja Lohbi* is the best tree we have tried for hedges, the dense growth being admirably adapted for breaking the force of the wind, and it grows so fast that we may soon have hedges from 10 to 20 feet in height, while it may be clipped into a close compact mass.

### FRUIT FORCING.

**PEACHES AND NECTARINES.—Early Houses.**—The trees from which ripe fruit will be gathered about the end of May and through June will now require the final thinning of fruit and wood, and when this has been completed the young shoots which have been allowed unrestricted growth during the stoning period (about six weeks) should be neatly tied to the trellis, and the points or apexes of the fruit be elevated by means of these latter fixed across the wires of the trellis. Quality being always preferable to quantity, healthy trees well furnished with active roots in inside borders may be allowed to carry one fruit to each square foot of trellis covered with foliage, whilst Nectarines may be left a little thicker; but nothing is gained by leaving a great quantity, which accounts for this fruit often being small, badly coloured, and poor in flavour, as the formation of the stones weakens the trees, and the fruit in consequence when ripe is small and worthless. It also permanently injures the trees. Shoots which emanate from the bearing wood of the current year should be allowed to grow evenly over the trees without being stopped, as they will become the fruit-bearers next season; remove other shoots left between them and the terminals. Do not stop terminals until they reach the extremity of the trellis; but shoots that will be removed after the fruit is gathered will only require moderate extension, being pinched when the last swelling for ripening commences. Ample supplies of liquid manure at a temperature of about 75° will be required by the roots, the great strain of the crop and the extensive breadth of foliage exposed to the sun will enable the trees in properly drained borders to take large quantities of water. Premature ripening may most frequently be traced to an insufficient supply of water to the roots through the last stages. When the fruit is advancing for the last swelling, the temperature by day may be considerably increased, provided the trees can be allowed to rest by night, when a rather free circulation of air will add greatly to the colour and flavour of the fruit. Syringe twice a day with clear soft water, as water containing lime disfigures the fruit, and endeavour to have the foliage quite free from red spider as the ripening stage approaches.

**Succession Houses.**—Follow up disbudding until every shoot that is left will have full space for development and exposure to the solidifying influence of light and air. It is no use trying to hasten the stoning process, as the fruit must have time, an equable temperature, and generous treatment. Disbud the trees in late houses, and thin all small and badly placed fruits, leaving a fair per-centage for choosing from when the most promising take the lead. Syringe copiously when the weather is fine, and ventilate by night as well as day when it is desirable to have the fruit as late as possible.

**FIGS.—Early Forced Trees in Pots.**—The fruit will soon be ripening, and on this account the supply of moisture will have to be reduced while ventilation may be increased. Much judgment and great care will have to be exercised in the management, as the trees laden with fruit in every stage of growth the daily routine must meet the wants of the trees in respect of the succession as well as the ripening crop. The trees, being surrounded with turves and a mass of roots, will require plentiful supplies of warm water. The surface of the plunging material and the lower part of the trees will need regular syringing, and as the fruit is gathered, it being well to do it closely, the trees may be well washed overhead. This occasional washing assists in restoring the wasted energies of the trees, keeps them free of red spider, and keeps the successional crop steadily advancing. Fire heat is necessary to maintain a temperature 60° to 65°, and 70° to 75° by day, with a rise of 10° to 15° from sun heat. Any strong lateral growths that require stopping and tying must be attended to, as good Figs cannot be obtained without a free circulation of warm air and exposure of the fruit to sun and light.

**Succession Houses.**—The weather has been more favourable of late, and under those conditions succession crops have made satisfactory progress. If not already stopped and tied down no time should be lost in getting this done, as the fruit will soon begin to show signs of swelling for ripening, and if, as is often the case in succession houses, the trees have a very heavy crop, a general thinning should be made as the work proceeds. It is a great mistake to suppose that a fruit tree, particularly a Fig, is more likely to mature a crop by being oppressed with a load that is enough for two, and it certainly results in complete loss of quality, and very often of the entire crop of fruit. The general routine will consist of

good root-feeding with tepid liquid manure, or clear water through a heavy mulching, plenty of heat, air, and a good syringing twice a day. The best time to perform the first syringing is when the temperature is beginning to rise, and the second in the afternoon after closing with a temperature of 80°, and sufficient sun heat that will raise it to 85° or 90°.

*Trees in Pots for Next Year's Forcing.*—Have these well advanced in order that they may have time to make a good thoroughly solidified growth, and a long and complete rest before they are wanted forced. By constant stopping and feeding young plants may be kept growing for a considerable time, and they soon make large trees; but size of tree is had at the expense of fruitfulness, hence a small tree with stout, short-jointed wood thoroughly ripened and rested, is more prolific and profitable.

**PINES.**—Up to almost the present time the deficiency of solar assistance in forcing operations this season stands almost unparalleled, hence recourse to hard firing has been continuous in order to keep up the heat in the various compartments. After such a period it will be necessary to be attentive to details of management, especially to the ventilation and the means which are employed for resisting the powerful effects of sunshine. Admit air slightly at the apex of the house early in the morning whenever there is an indication of a sunny day, and give a little protection from sunshine early to those plants which are placed at no great distance from the glass. Recently potted plants—suckers and others in small pots—must have immediate attention when they have filled the pots moderately full of roots; for this purpose the pots, soil, &c., which will be required for shifting the plants, should be ready to hand, and in a warm moderately dry condition when used for potting. Let the soil be lumpy, and the plants firmly embedded in it. Good yellow loam full of fibre and not too porous cannot be excelled for Pine cultivation, and in the case of the loam being very tenacious an addition of road scrapings will be highly beneficial. When the plants have been shifted into larger pots the bottom heat should be well sustained at 90° to 95°.

#### PLANT HOUSES.

*Tydas.*—As evergreen varieties, such as Madame Heine and others that form no underground stems, cease flowering, all healthy cuttings should be taken from them and inserted in sandy soil in pots and pans. Generally sufficient cuttings can be obtained for next year's stock, and when this can be done the old plants can be thrown away. Every cutting will be certain to root if placed under a handlight and shaded from the sun in some structure. After the cuttings are rooted they should be grown under moderately warm conditions, and by the time it is necessary to strike them for spring flowering some strong cuttings will be produced. If sufficient stock for next season cannot now be obtained, a few of the old plants may be cut down to within 6 inches of the base, and if kept in heat cuttings will soon be produced.

*Justicia calytricha.*—This is one of the most beautiful plants that can be grown for the decoration of the conservatory or intermediate structures from December until the end of March. The beautiful light feathery plumes of this plant last a long time, and after the first flowers fade a second crop is produced. This plant must be grown on from cuttings annually, for old plants seldom grow with such vigour or produce such large plumes of flowers as young plants. Old plants from their slow stunted growth often become a prey to scale, which is not the case where plants are raised from cuttings every year, provided they are not grown too warm. Old plants that have flowered should be pushed into growth in a warm house, for the sooner cuttings can be obtained the better. When strong cutting have been produced they should be inserted singly in small pots, and if kept close in the propagating frame every one will root. They should be grown warm until they are established in 8-inch pots, and from this stage an intermediate temperature should be given them. After the middle of July they should be grown in cold frames.

*Begonias.*—*B. manicata* and *B. hydrocotylifolia*, that were brought into flower by the aid of stove heat, and have since been in the conservatory, are now past their best. The last named is decidedly the best for conservatory decoration, the flowers not only last longer but are larger and more showy than those of the former. These plants must be raised from cuttings annually. The cuttings should be 3 inches in length, and remove the large leaves before they are inserted in 3-inch pots. Insert them at the side of the pots, or when full grown they generally creep over the edge of the pot. If placed at the side and the same treatment is given when placed in their largest pots, the head of the plant will be near the centre by the time they are fully grown. These root freely in any structure where they can be shaded from the sun and a temperature of 60° maintained. Insert the cuttings in a compost of loam, one-fourth leaf mould, and about one-seventh of manure and a little sand. A good pinch of sand should be placed in the centre for the base of the cutting to rest upon.

*Linum trigynum.*—If cuttings of these have been rooted place them into 2½-inch pots and grow them warm until they are established. When in this stage gradually prepare them for an intermediate temperature, in which they will make a sturdy growth and resist the attacks of red spider if carefully watered and liberally syringed. This insect is a great enemy to this plant, and is certain to prey upon it if the plants are grown under stove treatment. Cuttings may still be rooted if sufficient stock has not been obtained.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

*Shrubby Calceolarias.*—These having been duly stopped, will now be breaking strongly, and unless well hardened off and transplanted to

fresh and more roomy quarters will quickly spoil. If the flower beds are empty there is no reason why they should not at once be finally planted out. They delight in a fairly rich soil, and should be lightly protected when necessary with branches of evergreens. In most cases it will be advisable to hed them out in frames or rough pits preparatory to finally transplanting, this being altogether preferable to potting or boxing them off. We put out several hundred in a rough pit, protecting with mats only. The bottom is hard and faced over with ashes, on this being placed a well-trodden layer of leaf soil, short manure, and common soil, to a depth of 4 inches, finishing off with about 2 inches of fine light soil. The plants are firmly planted in this at about 6 inches apart each way, watered, shaded for a few days, and subsequently kept supplied with water as required. At bedding-out time each plant can be moved with a good square of soil and roots, this coming clean away from the ashes, the removal being unattended by a severe check, and very few are lost. Failing a frame or pit, a wide trench might be formed in the garden and prepared as just recommended, and in these the plants may easily be protected by laying branches of evergreens, mats, or other protecting material across.

*Violas.*—Young plants of these that were wintered in frames now require attention. They cannot well be established too early in the beds where they are to bloom, and should have very liberal treatment. A good dressing of any kind of short manure or leaf soil ought to be well forked in, not so much to stimulate strong growth as to preserve plenty of moisture about the roots. A summer mulching should also be given, and then the Viola heds will be among the gayest, no matter how hot the summer may be. The blue varieties are most effective in mixture with either silver, golden, and bronze Zonal Pelargoniums, spaces being left for the latter when the Violas are put out, a broad band of Iresine Herbsteri or I. Lindeni with a margin of silver or golden variegated edging plant completing an attractive bed. If the heds are occupied with spring-flowering plants the Violas must be hedded-out temporarily, or somewhat similarly to the Calceolarias, and all flowers should be kept picked off all of them. Now is the time to divide the old plants, as if this is delayed to June they seldom make satisfactory progress. The frames now cleared of Calceolarias and Violas should next be filled with seedling Pentstemons, Antirrhinums, Lobelias, Ageratums, or other kinds for which more room is required, this liberating boxes and pans for other purposes.

*Seeds to be Sown.*—If not already done no time should be lost in sowing in a mild heat such useful annuals as Stocks, including Ten Week, East Lothian, and Earliest-flowering Autumn; Asters in variety, Marigolds of sorts, including, if a substitute for Calceolarias is required, either the Miniature Yellow or Tagetes signata pumila, Everlastings, Perilla nankinensis, Zinnias, including the dwarf and very free-blooming Haageana imbricata flore-pleno, Zea japonica, and Ricinuses. The latter are best sown singly in 5-inch pots and given a light position directly they are up, while the Maize we sow singly in 2½-inch pots, and plant out before they are root-bound. All the foregoing germinate quickly, and when sown rather late may be kept growing without a check. In the open border we are now sowing seeds of Mignonette in quantity, planting other annuals among the plants later on; Sweet Peas, Calliopsis in variety, Candytuft, annual Chrysanthemums, Clarkias, Clintonia pulchella, Convolvulus, Centaurea cyanus (Cornflower), Collinsias, Eschscholtzias, Godetias, Helichrysums, Hibiscus africanus, Larkspurs, Lupines, Malope, Love-lies-bleeding, Nasturtiums, Poppies, Salpiglossis, Tropæolums, Sunflowers, Virginia Stocks, Senecio elegans, and Portulacca. The ordinary garden soil being in the best condition imaginable, this is quite good enough for covering seeds, and they should germinate quickly this season. The seed should not be sown like Mustard and Cress, but much more thinly, as only a few plants in each patch invariably give a better and more lasting display. Sown thickly the seedlings spoil each other.

*Ornamental Grasses.*—These are very pretty in the borders, and when cut and dried before they are fully ripe they are of great service to the decorator. They are usually sold in collections as imported, each containing from six to twenty-four sorts. These may be sown at once, either in lines on a spare border, or better still in patches in a mixed border and according to their respective heights. As the packets do not bear any instructions as to the heights the various sorts attain, our own measurements may be of service to intending growers. Agrostis elegans, A. namaquensis, A. papposa, each 1 foot; Briza geniculata, B. maxima, each 1 foot; B. gracilis, three-quarters of a foot; Anthoxanthum gracile, three-quarters of a foot; Coix lachryma, 2 feet; Gymnothrix latifolia, 2½ feet; Glycerium argenteum, 9 feet; Hordeum jubatum, 2½ feet; Lagurus ovatus, 1 foot; Lasiagrostis, 1 foot; Pennisetum longistylum, 2 feet; Stipa elegantissima, 2 feet; S. splendens, 3½ feet; and S. pennata, 1½ foot.

## THE BEE-KEEPER

### AN INTERESTING EXPERIMENT.

THE past winter has been in many cases more than usually disastrous to bees. Many stocks have died, some of starvation, others from the effect of damp, all from mismanagement. A little individual enterprise would have saved not a few fine colonies from an untimely end to yield profit in the coming season. Snow after snow, keen frost and chill cutting east

wind, may all be defied by a careful attention to matters of detail, and, even in apparently desperate cases, much may be done to remedy earlier neglect. The most critical time for stocks this year was in the early days of February, when a brief period of milder weather gave every bee-keeper an opportunity—not, to be sure, a very favourable one—to attend to the wants of his bees and see if there was a sufficient food supply to last until the middle of April.

Those who made use of the brief interlude between two storms of frost and snow of long duration had every reason to congratulate themselves upon their forethought. How few actually did make such an examination is proved by the sad havoc the last six weeks of frost and snow have wrought in many apiaries. This year has been so phenomenal as regards weather that the opportunity once lost was gone until the middle of March, when a sudden change to mild weather and bright sunshine enabled the bees to take a general flight. What, it may well be asked, could have been done to give a food supply to light stocks when 3 inches of snow were on the ground for many days, and 15° to 20° of frost at night? Candy at least might have been given, but syrup might equally as well have been given if sufficient care were taken to prevent the bees from flying when the weather was unfit for flight. The method attended with the greatest amount of success during the continuance of a storm, if food has to be administered, is to place an ordinary bottle feeder on the stock, wrapping it up as warmly as possible and absolutely preventing the flight of a single bee. Has anyone actually proved by experiment how long a strong stock may be confined to its hive while feeding is going on and still be found in the best of health? From the 12th of February until the 19th of March this year a very strong colony has been confined while feeding was going on and is now in excellent health, and far in advance of some other stocks apparently in better condition six weeks ago.

The means taken to produce this result were exceedingly simple, and although I hope that there may be no necessity for years to come to adopt a plan so much opposed to the general rules of bee management, it may be of use as showing what can be done to prevent loss when an earnest attempt is made. It is well known that at night bees are quiet and content to stay in the hive even in the mildest weather, and it is also reasonable to suppose that if day and night can be made to appear almost identical absolute quiet will prevail in the stock. Acting upon this idea a thick screen of old carpet was provided and wrapped closely round the hive, leaving the alighting board free from obstruction and the entrance open to its widest extent, so that no false excitement should be caused by the inability of the bees to leave the hive. This screen being put in position boards were placed outside to shut out the least ray of light and to shoot off the rain and snow, the feeder put in its place, and beyond filling the feeder no more care was bestowed upon the stock, except occasionally at evening removing the covering for an hour or so to renovate the air; but this was not a necessity, as the stock being in a hive standing on four legs 8 inches high admitted a constant current of air beneath the shade. The result was satisfactory; but little movement could be noticed, and the colony seemed almost in a normal condition through a long cold night of nearly a month's duration. There was no fouling of the comb nor of the hive, and on the first cleansing flight not a trace of dysentery could be perceived, and now at the end of April there is no stock more prosperous nor does any give promise of greater profit hereafter.

I was told by "those who knew" that any attempt to confine the bees while feeding was going on would result in failure, but have been able to prove that such is not the case. How long such a confinement would be safely endured it is difficult to tell, but possibly for a long time, and it must not be forgotten that, while the snow was on the ground, bright warm sunshine made the air as mild as summer, and necessitated very careful covering of other stocks to prevent a wholesale destruction; and even then some few bees did leave their

lives, and curiosity led me to try the extent of their vitality, for, picking a fine bee out of the snow—how long it had been there it is impossible to say—I took it into a warm vinery, and revived by the genial warmth it soon regained health and activity; about ten minutes later I again laid it in a wreath of snow, and once again it fell asleep, and so it lay for two hours and a half, when it was taken into the warm atmosphere of the vinery, where it speedily awoke and seemed not in the least the worse for its adventures, and was carefully restored to the hive from whence it came. The disappearance of the snow, and its not having since returned, prevented any further experiment, which must be postponed till next winter unless we are victimised by another storm.

In concluding, let me say that although I am not aware that the former of these experiments has been carried out and described, it may have been put to the test by others. The latter is not by any means new, it having been a fact long ascertained that bees have a surprising amount of vitality and recuperative energy, but it would be most interesting to know how long a bee would remain in this death-like sleep and yet recover upon being placed in a warm place for a brief period. There seems to be a system, and one not seldom practised, of trading in another's wares. Now this is most reprehensible and discreditable to all concerned; although in many cases it is no doubt accidental, in some I fear it is wilful. It will be well if each one will do all he can to expose any such violation of trust, and thus make those who deserve the credit of any useful invention to receive the praise due to them for their efforts to improve and simplify the appliances used in our apiaries.

Will "A Lanarkshire Bee-keeper" kindly say where the "honey-press" about which he writes can be purchased, and at what price?—FELIX.

#### APPLIANCES—FRAMES FOR HIVES.

WILL your correspondent, "Lanarkshire Bee-keeper," kindly state the price of his honey press, which he alluded to a fortnight ago in the Journal; also the cost of a wax extractor on the principle of his own? and the price of his "Essay on Bee-keeping," and if it treats the subject of queen-rearing and forming nuclei for an autumn supply of queens?

I have at present three stocks, two in standard frames, and one in frames 6 inches deep and the length of standard frames. One stock is composed of two driven stocks from straw hives, the next an old stock, and the third a swarm of last year. All my hives have perforated zinc floors with a slide underneath, and consist of hives proper in cases with lateral slides on the top. The driven stock has eight or nine standard frames fed with 30 lbs. of syrup. The old stock I transferred from standard frames into a shallow hive 6½ inches deep, and fed with 30 lbs. of sugar. The swarm retained eight or nine standard frames with honey and pollen, and fed with syrup to make its supply of food equal to the other hives. They appear to have wintered in good condition. I scarcely saw a bee from November to the middle of March. I have not yet examined them, for as the hives stand in an exposed position I am afraid to open the hives lest it chills the brood. The hives are well supplied with food, and I shall leave them alone until a fine day. They have a good supply of pollen in the Furze blossoms close by, but the wind is too strong for the bees to gather it. I am not going in for spring feeding this year. I did so last year with a stock, but it turned out very late after all my feeding. This might, however, have been the result of over-manipulation. I want to prepare them for June Clover, and to raise some queens to be held in readiness to introduce in the autumn, and I should feel thankful if your correspondent would give me a few hints how to do so with my stocks as I have explained them. Ought I to add more frames when I change them to clean hives? I want about three or four queens in reserve for autumn.—NORFOLK BEE-KEEPER.

[1, The price of an all-iron honey presser last year was 35s. complete, being 5s. dearer than those partly of wood. Every bee-keeper should have as an accompaniment a honey drainer, which costs from about 20s.

2, The price of a wax extractor 15 inches in diameter and 18 inches deep over all, including sieve, sieve holder, and steam generator, is 16s.

3, The price of the "Essay" post free is 7d., and treats briefly on raising queens. The subject will be fully treated in the columns of this Journal as the season advances.

Eight or nine standard frames to a hive are too few for either swarms or for producing surplus honey. Take the first opportunity to enlarge all the hives to double that number of frames, on the tiering principle. When bees rest peacefully during winter, which they will only do when dry and well provided with provisions, they as a rule come out well in spring, and are profitable by summer. All meddling with bees during winter or spring is injurious in some form or other, which you seem to have proved.—A LANARKSHIRE BEE-KEEPER.]

## TRANSFERRING COMBS.

I HAVE this winter been altering hives in accordance with advice given to me by your correspondent, "A Lanarkshire Bee-keeper." As I highly approved of this advice I set to work at once to follow it. I have altered three hives, or rather six, and each hive now consists of two, one placed over the other. Originally they were oblong hives, each containing thirteen combs, each comb measuring, inside measure,  $7\frac{1}{2}$  deep by 13 wide. A number of years ago my hives contained seventeen or eighteen combs, all on one level, and the consequence was that in winter the outside combs got mouldy and the wooden floors damp and dirty; but the population was very large, far larger than the smaller hives.

"A Lanarkshire Bee-keeper" advised a double-tiered hive and ventilating floor with perforated zinc bottom. I have adopted this principle. The hives now contain eighteen combs—nine below and nine above. They are about square inside and 16 inches deep, and will retain the heat better. There are underneath each hive two drawers, like bird-cage drawers, only a little deeper; they are placed one above the other. The upper one has a floor of perforated zinc to allow *débris* from the bees to fall through, and the lower one has a wooden floor, which is covered with dry peat, as I think this will tend to keep the bees healthy and dry. The peat drawer can be drawn out and refilled at any time, without the bees being interfered with in the least.

I should be glad, now, of a little advice as to the future. I have three old pattern hives, each with a newly altered hive alongside, and I might transfer (when suitable weather comes) the thirteen frames with bees on them to the newly altered hives. I would place nine frames, containing all the brood and bee-bread, in the upper tier of the hive, while the four remaining frames would go below, filling up with foundation-filled frames. Is it desirable to do this now, while the population is small, or wait later, when there will be more bees to keep up the heat, or to wait for the young swarms? If not likely to throw back the bees, I would prefer to transfer the bees in the middle of May, so as to give them the benefit of the enlarged hive, and perhaps prevent swarming. The swarms here generally come off about June 20th. Perhaps "A Lanarkshire Bee-keeper" will help me.—A BEE-KEEPER.

[If the hives of bees are tolerably strong I would advise their being transferred to their new ones whenever a fitting opportunity occurs. Only fill the upper hive with five or seven combs in the centre, and one or two on either side with comb-foundation, filling the bottom one with foundation as proposed and the remaining frames, having those with brood under the brood ones in the upper box. If, however, the bees are weakly, wait a few weeks until they are stronger. The advantage gained by putting in foundation in the outsides of the upper box is to obtain as much white comb as possible. If the queen is young, prolific, and healthy, the increased space should prevent swarming; but without the former all the devices of man will not prevent it. The dried peat seems to me good in connection with hives, both as you have employed it, as well as for filling in space between the inner and outer wall, and perhaps in other ways in connection with the preserving of bees in a healthy state during winter.—A LANARKSHIRE BEE-KEEPER.]

## TRADE CATALOGUES RECEIVED.

Thomas Painter, Smallwood, Scholar Green, Stoke-on-Trent.—*Catalogue of Dahlia Plants.*

A. M. C. Jongkindt Coninck, Tottenham Nurseries, Dedemsvaart, near Zwolle, Netherlands.—*Catalogue of Trees, Shrubs, and Hardy Plants.*

Bruant, Boulevard Saint-Cyprien, Poitiers (Vienne), France.

\*\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance,

but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Epicurean Victory Pea (J. Smith).**—The sample sent is very good indeed. We will sow the Peas, and if the variety prove equal to the Epicurean we have already grown we shall be satisfied; if it excels it, as the name denotes, it will be of very superior merit.

**Acacia platyptera (William).**—Nearly or quite all large nurserymen who deal in stove and greenhouse plants can supply this Acacia, and as so many sell plants it would be invidious for us to recommend any particular dealer. Perhaps you have not applied to anyone for plants.

**Beetle Eating Plants (J. W.).**—Your beetle is the voracious weevil *Curculio* or *Otiorhynchus sulcatus*. We are unaware of any ready mode of riddance. They should be sought for assiduously, as they deposit eggs from which maggots are hatched, these in turn developing into weevils. Choice Orchids should be stood on flower pots inverted in larger saucers of water. It has been said that an infusion of aloes and quassia renders plants distasteful to these pests, but we have not had occasion to test the matter.

**Abnormal Lapageria (G. H.).**—The arrangement of the flowers is quite unusual, inasmuch as they turn upwards by an acute curve of the peduncle which is 2 inches long. This would obviously not be an advantage with a plant trained to a roof, but secured to a balloon trellis a densely flowered specimen would be highly effective. The spray you have sent appears to be an arrested growth, this often resulting in monstrosities, and it is uncertain whether the character could be fixed or not. You have nothing to lose by trying, and if you succeed in establishing plants in which all the flowers are produced like those on the spray before us you will, so far as we know, have a distinct variety.

**Rhynchospermum jasminoides to Flower in August (Constant Reader).**—To have this plant flower in August it would need to be retarded in a cool house with a north aspect; but as it is now in flower it cannot be had in flower again by August, as it must needs make a fresh growth, ripen it, and a season of rest. It is not a stove plant, only requiring cool treatment, and does well in a greenhouse.

**Supplying Water to Houses (Idem).**—The pipes will not convey the water from the large tank to the smaller ones in the houses, as they are 3 or 4 feet higher. The water must be forced into the smaller tanks from the larger one, and we cannot suggest anything better than a force or lift pump, or an ordinary pump at each tank, so as to draw the water from the large tank. For this purpose a lead suction pipe is best about  $1\frac{1}{4}$  or  $1\frac{1}{2}$  inch diameter. Could not the water be pumped directly into the smaller tanks by means of the horse pump? A stopcock on the main to shut the water off the large tank, and a branch pipe laid on to the tanks on the higher level would be the easiest way out of the difficulty, as the mere turning of the valve or stopcock would be all the labour necessary. Two-inch cast iron socket pipes would be the most suitable piping, or it might be lessened to suit the delivery pipe to the large tank.

**Moss Litter for Mushroom Beds (W. W. R.).**—Excellent crops are grown with this material after it has been used in horse stables, but it is much better adapted for flat beds under cover than ridges in the open. Such a small quantity as a ton is not sufficient for outdoor ridges, and you have also turned it over too many times and had it too long under preparation. The instructions to which you allude in Wright's book doubtless refer to the preparation of manure, of which the greater proportion is straw. If you only have a copy of the first edition you should obtain one of the last when it appears, as it will contain a great deal of additional information of service to inexperienced amateurs. If you did not cover the ridge a foot thick or more with litter the heat would be certain to escape. Try this plan now, and fermentation may even yet be excited.

**Grapes on Back Walls of Vineries (Ritterman).**—With the "Vines on the roof 6 feet apart and spurred so that ample light reaches the back wall," there is no reason why useful Grapes should not be grown there; but the light that you consider "ample" may not be sufficient for the production of first-class Grapes. We have seen very good Grapes grown under similar circumstances, and of the late sorts that were tried the Black Alicante proved the best. Gros Colman, however, was not in the trial, and it might possibly do very well. We should try both those varieties.

**Exhibiting Flowers (Gardener's Wife).**—If you were to exhibit flowers in a class from which the produce of professional gardeners is excluded, and you were awarded prizes, although you grew the flowers "entirely yourself," and your husband "did not grow any of similar kinds," the jealousy of other competitors might be aroused, and a protest lodged on the ground that you had benefited by the advice of your husband in growing the flowers. We have known a case of the same kind that led to long disputation and much unpleasantness, and although we believe the exhibitor eventually got the prize money, the cost incurred in securing it was a great deal more than the prize was worth.

**Cropping Vines (F. J.).**—When the laterals are very strong and the bunches small, two may be retained on one lateral "here and there," since it is obvious that two bunches weighing 1 lb. each do not require more support than does one bunch weighing 2 lbs. We have often seen two bunches on one lateral without any detriment to the Vines; but their strength and condition must in all cases determine the weight of the crop. If your Vines were materially exhausted by over-cropping last year, it would be unwise to make a similar mistake this season. The strength of the sub-laterals is a fair index of the Vine's strength, and if growths continue to be produced freely beyond the bunches until and after the Grapes colour, the crop is not dangerously heavy. By sub-laterals we mean the growths that push after topping the shoots, this requiring to be done several times during the season when Vines are in good condition.

**Chili Capsicum Culture (Vectis).**—The plants should be kept close to the glass until showing the second leaves, when they should be placed in 4-inch pots, three in each around the sides and not quite down to the seed leaves, keeping moderately watered, for if the soil is very wet they are liable to damp off, and shade them from bright sun until established. Place them in a light position, and allow plenty of room to keep the plants

sturdy and insure a branching habit. When the pots are well filled with roots shift the plants into pots 7 inches in diameter, and in potting lower them down to the seed leaves, or, rather, the joint where they were. Pot them moderately firm, the most suitable compost being light turfy loam with a fifth of well-decayed manure intermixed. A quart of soot may be mixed with each bushel of compost. Avoid over-watering the plants, but do not let them become so dry as to cause the foliage to flag. Fumigate upon the first appearance of aphides. Red spider may be kept under by syringing. When the pots are filled with roots liquid manure may be given, applying it weak and tepid. If the plants are well grown each pot would afford three dozen pods. The number would be much increased by superior treatment.

**Chrysanthemums for Exhibition (*Chrysanthemum*).**—Plants of Chrysanthemums now showing flower buds should have all such buds taken off, and when the breaks follow and are strong select three and tie them to a stake; but, as sometimes occurs at this stage, if two of the shoots are strong and one weak leave two only, and select a third shoot when the plants break again. Naturally, three blooms to a plant of such large-growing kinds as those you name are sufficient, and in the case of smaller-bloomed sorts, such as Bouquet Fait and Mrs. G. Rundle, for instance, you may retain four stems, which will produce the same number of blooms if all other details necessary are carried out. Such plants as you name in your second question would be perfectly eligible to employ a group of plants in the class you mention for the show in question, but we do not think variegated Fuchsias and Pelargoniums at that season would carry much weight. We have seen variegated Abutilons used for such a purpose with excellent effect, but too many should not be introduced on account of the colour of the foliage; but if you could have a few Palms, such as *Scaforthia elegans*, *Cocos Weddelliana*, *Areca lutescens*, the group could be made much more effective.

**Mushrooms Outdoors (*Black Mountain*).**—They are grown near London on ridges 2½ feet wide at the base, sloping to about 6 inches at the top, which is rounded, the height being the same as the base. In the north the ridges are better 3 feet wide and high. The manure from horse stables is composed of about half straw and half droppings, fermented, partially decayed, and turned till it is sweet. The ridges are made very firm, and after the heat rises and falls again to about 90° two inches beneath the surface, spawn is inserted 9 inches apart, a brick being broken into eight parts for this purpose. The ridges are at once covered a foot or so thick with litter to maintain the heat about 80°; as soon as the spawn is seen to be spreading the ridges are cased with good soil, which is beaten 2 inches thick. The ridges are again covered, and if a thermometer laid on the soil under the litter registers 60° the ridges will be warm enough. In winter they are sometimes covered 2 feet thick, but half that covering often suffices. July is the best month for commencing, the next best December. If you commence now you will fail unless the ridges are in a cool shaded place. We know a grower who gathered and sold 7 tons of Mushrooms from outdoor ridges last year. All the details of culture are given in Wright's "Mushrooms for the Million," the fourth edition of which is being reprinted with a supplement.

**Marechal Niel Rose—Blood Manure (*S. L. B., Liverpool*).**—You have erred in not pruning the Rose, and it is not very easy for anyone to comprehend the real condition of the plant without seeing it. There is no doubt that the plan of cutting back the growths of this Rose after flowering answers admirably in many cases—that is, when roots are active in good soil and there are good buds on those parts of the stems to which the shoots are pruned. If you can see prominent wood buds on a healthy part of the stems you may cut the plant down to them; if there are no such buds, and especially if the root-action is defective, such severe pruning might not result in free growth. Free root-action is the most important factor in producing healthy growth, and this can only be insured with good soil and judicious applications of water. Mistakes in watering nullify the effects of the best of soil, and if this is alternately too wet and too dry nothing can thrive. Liquid manure does more harm than good when given to plants that can derive sufficient food from the soil; when they cannot, and the pots are filled with roots, manurial applications once or twice a week are valuable. Keep your Rose in the lightest position in the greenhouse till the weather is mild, then place it outside in a shaded place for a week or so till the leaves acquire sufficient texture for withstanding the sun. If taken direct from the greenhouse to the full sun the foliage will be scorched. The pot must be shaded from the sun by either plunging it in ashes or sinking in a larger pot when the plant is stood outside. It will not grow satisfactorily in a greenhouse in summer the roof of which is covered with Lapagerias. We know of no means of making hard blood manure soluble than smashing it small and letting it remain a sufficient time in water. An ounce to a gallon of water is ample for strong-growing plants in pots, such as Chrysanthemums; half that quantity for weaker, such as Fuchsias and the others you name; nearly 2 ozs. per gallon may be given to Dahlias when they attain strength, and Roses in the open air. We consider a mixture of superphosphate of lime and sulphate of ammonia preferable to blood manure in the condition you describe.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*C. S.*)—The Orchid is *Dendrobium Devonianum*; the other is *Fabiana imbricata*.

**Feeding Bees with Old Honey (*J. D.*).**—If your bees are in want of food, and the last year's honey in the comb is good, and can be put inside the hive so as to constitute part of its comb, do so. But if it is in any way inferior do not give it to the bees. Neither on any pretext whatever lay it outside for the bees to find, as by doing so it would make them vicious and cause robbing, resulting in the loss of queens. If foul brood is anywhere near some of your bees are sure to catch it. If the combs are not such as will fit into the interior of the hive, place them at the entrance of the hives

after the bees have ceased flying, and remove them before they commence in the morning. Do not feed bees with honey that is sour, thin, or candied; use such for domestic purposes and feed the bees with sugar.

## COVENT GARDEN MARKET.—APRIL 21ST.

Trade falling off, and prices of house fruit lower.

### FRUIT.

### FORAGE CROPS.

To have a few ricks of hay to spare in March or April may certainly be taken as an indication of sound practice by either the home or tenant-farmer. If really good such forage can always be disposed of advantageously, for it can be retained in the ricks till prices invite a sale. Occasionally after a long drought or otherwise unfavourable season meadow hay will reach the high figure of £7 per ton, but £4 per ton may be given as an average price for hay in the rick. Farmers who are fully alive to the feeding value of straw, now dispose of most of their hay, and depend almost entirely upon chaffed straw as forage for home consumption. Under good management the chaffing is by no means a daily or

weekly process, but enough is done to fill a chaff house or one end of a barn, the chaff being packed so closely together that it heats sufficiently to develop an aroma almost as fragrant as that in good hay. Straw so managed becomes as palatable as it is nutritious, and it is given to horses, cows, store cattle, and sheep.

After the first outlay upon laying down land to permanent pasture there is a permanent reduction both in the labour of men and horses of the farm, and such reduction may also be regarded as permanent when layers are sown for three or four years; only we must never forget that pastures, whether temporary or permanent, must have an annual dressing of manure of some sort or other. That obtained by sheep-folding is the most economical, that by the application of farmyard manure the most expensive. As there is practically a limit to sheep-folding upon most farms, we adopt the happy mean placed at our disposal in the guise of pure artificial manure. An annual dressing in February of such manures keeps the soil stored with fertility sufficiently for the requirements of the plants growing in it, and, what is still more important, the sustained vigour of the pasture leads eventually to a remarkable increase in the bulk of the crop. It does not answer to suffer the pasture, or rather the soil in which it grows, to become almost exhausted of fertility before giving more manure. We must not suppose half a dressing yearly, or a full one on alternate years, will suffice, and if we can contrive to apply liquid manure to any or all of the pastures immediately after the grass is mown we insure a quick strong growth at once. This is a matter worthy the especial attention of the home farmer for the pasture of park land under his care, for which the sewage of the mansion ought to be available. The sewage tank should be, if possible, in the park, and far enough away from the buildings to avoid all risk of nuisance from foul odours. A pump is fixed in the side of the tank most convenient for approach with a water-cart, and the sewage is distributed upon the pasture in the same manner that town streets are watered. We need no close calculation as to the exact proportion of nutriment in a given quantity of sewage. It is sufficient for our purpose to know that it imparts fertility to the soil, that its action is more prompt than that of solid manure ever can be, and that it costs nothing. This use of sewage is one of the little matters so frequently neglected on the home farm, yet it is of such importance as to merit especial attention, and we certainly should insist upon having a manure tank, pump, and distributor for every large establishment.

To regard permanent pasture as a panacea for the agricultural depression is wrong. Extreme measures are seldom safe ones, and we fail to see how any farmer, but especially he who has rent to pay for his land, can afford to lay down much land at once. Far better would it be to sow a few acres year by year till a fair proportion of the farm is in pasture, and to do this work really well. Mr. Martin J. Sutton's new book on permanent and temporary pastures is a pleasant sign of the favour with which this branch of agriculture is now regarded, and farmers will find the investment of a guinea in its purchase a profitable outlay, if only they will try and shake off the too common feeling of prejudice against "book learning," for this work is thoroughly practical, and its teaching sound. To those who have hitherto been content to sow annually Red Clover for a supply of green food and stover, it offers some valuable hints on mixtures for leys or layers of one to four years' duration. In the first we are recommended to sow Italian Rye Grass, Perennial Rye Grass, Cocksfoot, Broad Clover, Cow Grass, White Clover, Alsike, and Trefoil, preference being given to some of these for hay, and others for grazing, and the reason for such preference is fully explained. In the second we have a large proportion of Cocksfoot—of which, by the way, we regret to find mention in another part of the book as "the Fashionable Grass," and we submit that it is much too valuable a forage plant to be spoken of thus slightly—Timothy is added, and more Perennial Rye Grass, White

Clover, and Alsike used, while the entire quantity of seed is increased. For three and four years the character of permanent pastures is approached more closely, but the finer Grasses are excluded, the Fescues and Foxtail being added. "The first year's crop," we are told, "will mainly consist of Rye Grasses and Clovers, but the bottom of a three or four years' ley may be expected to improve for at least two years, and the Foxtail, Timothy, Cocksfoot, and other plants will increase in bulk in the third and fourth seasons."

Other forage plants worthy of especial attention are Lucerne and Sainfoin, which latter is very useful where it is found to answer. We have just sown seventeen acres of it in a deep rich loam on a calcareous subsoil. We prefer sowing Lucerne in drills wide enough apart to admit the horse hoe for clearing purposes, and then with an annual dressing of manure we are able to retain it for several years.

#### WORK ON THE HOME FARM.

Mangold sowing is now almost finished once more, and our payments for artificial manures are at an end till autumn. This is the only matter in which we have been at all extravagant, but we hope it was done wisely and well. At any rate we carefully considered ways and means before giving a single order, and we kept our balance at the bank carefully in mind, for we have resolved that nothing shall induce us to borrow money for farming. On the other hand it is unwise to allow much money to remain idle in the banker's hands; far better is it to have money at work, and to turn it over as quickly as possible. Little profits accumulate, only to secure them we must be up and doing, and be prompt to seize every opportunity as it occurs. The strong prejudice which exists in the eastern counties in favour of Orange Globe Mangolds has induced us to procure seed of the best sort of it for each of our bailiffs; but we have had six acres specially prepared and sown with Long Red Mangold under our own eye upon the home farm, our aim being to show that this sort of Mangold can be made to answer under ordinary care, and afford results superior to those yielded by any other Mangold. Swedes and White Turnips will follow in due course in land now under Rye. This Rye has had a hundredweight of nitrate of soda per acre, and after it has been folded with ewes and lambs we consider it will be sufficiently stored with fertility to yield a good crop of roots. The Swede and White Turnip land upon which the flock was folded recently has been ploughed and sown with Black Tartarian Oats. It was originally our intention to have sown Spring Tares there, but we decided to have the Tares after some Rye Grass on an off farm, where we shall have the option of folding the Tares or ploughing them in. That off farm is in such poor plight that there was a heavy loss upon it last year. Some three or four years ago it was thrown upon the landlord's hands by a tenant who had "farmed it out," and it has proved no light matter to bring it back to good condition. Land undrained, foul with twitch, poverty-stricken, is not easily set right. Let landlords bear this in mind, and if by reasonable concessions it is possible to induce tenants to farm well and to retain their holdings, let there be no hesitation about the concessions, or in other words about a fair reduction of rent. We are now, at any rate, fully face to face with the depression and its results, and it may be taken for granted that the letting value of land can never return to the high rates of ten years ago; colonial influences will prevent that. If farmers have had a reduction of rent proportionate to the falling off of prices in farm produce they certainly have no just cause of complaint.

#### REMARKS.

11th.—Showers in morning, otherwise fine; faint lunar halo at 9 P.M.

12th.—Glorious day.

13th.—Fine and pleasant, but cloudy after the first part of the morning.

14th.—Showery early, fine and pleasant afterwards.

15th.—Fine bright morning, spots of rain at times in afternoon.

16th.—Generally fine and pleasant, but occasional spots of rain.

17th.—Dull and drizzly.

Temperature much the same as in the previous week, except that the nights were rather colder, there being frost on three nights.—G. J. SYMONS.

## THE PAST AND FUTURE OF THE ROYAL HORTICULTURAL SOCIETY.

**F**OR some time past a feeling has been growing and deepening that the position of the Royal Horticultural Society as regards its location and tenure at South Kensington is the reverse of satisfactory, and if we are not misinformed preliminary steps have been taken with the object of severing a connection that is to say the least incongruous, and which must sooner or later terminate, it may be abruptly, and result in the pitiable spectacle of an old chartered Society being cast out on the world without a habitation.

Nothing can be more unwise than to take any rash steps that may lead to sudden and fundamental changes in established institutions; at the same time it is none the less necessary to avoid a rigid adherence to existing arrangements through the force of sentiment alone. When the circumstances of the time indicate with sufficient clearness future possibilities, and these are not such as can be favourably anticipated, the most destructive of all policies is to stand still and trust to chance to avert in some miraculous manner the danger that is seen looming in the distance. It cannot be said that those in whom the interests of the Royal Horticultural Society are vested have acted precipitately in the conduct of its affairs. On the contrary, there is not wanting a feeling that if there is a lack of anything it is of a disposition, as it is expressed, to "launch out." It is very easy for persons of sanguine temperament and free from the responsibilities of office to advocate changes and force on the popular remedy for all ills—an "advanced policy." It is well that outside pressure should be exercised as a stimulant to progressive action in consonance with ever-changing circumstances; but it is nevertheless imperative that responsible officials consider well before taking a "new departure" that may be fraught with important consequences. The change now projected is too momentous in its nature to be lightly made, and it ought not to be made without very serious deliberation; and considering the habitual caution of the Council of the Society, it may be reasonably, not to say confidently, expected that if anything like an unanimity of feeling prevails in favour of a transference of the seat of government, that very strong reasons exist for the important step contemplated.

What are the facts of the case? In the first place, even if the Royal Horticultural Society had a certainty of tenure at South Kensington, its objects and those of the Royal Commissioners, who are the owners of the property, are far from being identical. That of itself, however, may not be sufficient to justify a divorce, though it is evidence of the initial mistake that was made in the union that was effected in 1859. For some time anterior to that date the Horticultural Society had been in financial difficulties, mainly through unremunerative expenditure on shows and general unpopularity. In 1856 it was only by a special effort of earnest horticulturists the Chiswick Gardens were saved, and

a proposal was made to effect an union with the Crystal Palace Company. In 1858 it was decided to sell the Society's house in Regent Street, and it was sold in the following year, the Chiswick Gardens being again saved, but only by the strenuous action of practical men and against the proposal of the then Secretary and Council. The library was also sold. The late Prince Consort then became President, and first acted in that capacity, attended by the Queen, at a show in St. James' Hall. In the meantime the great scheme was propounded, under which a vacant space was to be converted into a splendid garden, and the Society, which was to share in the undertaking, was to realise a brilliant career. No more debt, no more contentions, nothing but harmony was to reign, and a cloudless future was confidently anticipated—by the promoters of the scheme, but not by all who were concerned for the best interest of the Society as the exponent of scientific and practical horticulture in this country.

The meeting, at which the decision was arrived at committing the Horticultural Society to enormous responsibilities, was held in the theatre of the Society of Arts on July 20th, 1859, being the adjournment of a previous meeting held on June 9th. The opening meeting, which was described in our report of it as "one of the most important that was ever held since the establishment of the Society, to consider a proposition which emanated from the Royal Commissioners of the Great Exhibition of 1851 for the construction of a grand horticultural garden on a plot of ground in the possession of the Commissioners at Kensington." The attendance was small, "being by no means commensurate with the importance of the subject." Dr. Lindley in advocating the scheme pointed out that the Council had been in communication with the Commissioners, who wished to know if the Society would form a new garden upon the ground placed at its disposal, and that a Council meeting had been "held at Buckingham Palace, at which the Prince Consort presided, and His Royal Highness thought that the proposition was of sufficient importance to be discussed by the Society at large." It was not, however, so discussed; for Mr. Charlwood proposed that a circular should be sent to every member with full details of the plan. He objected to the scheme, because it was not one which went to further the objects for which the Society was founded, and deprecated the outlay of £50,000 debentures. No notice was taken of that proposition; but a resolution was carried in favour of the plan generally, that the negotiations should continue, and the final proposals of the Commissioners be reported as early as possible. They were reported to the adjourned meeting on the date named, "at which there were not at any one time thirty-five members present." Yet the momentous resolution was passed "that this meeting approves of the steps taken by the Council; authorises the negotiation with the Royal Commissioners to be continued, and empowers the Council to proceed to raise the sum required for the construction of the garden at Kensington Gore, and if the money should be obtained to complete the arrangements."

There can be no doubt that the decision was arrived at with the greater alacrity in consequence of Mr. C. W. Dilke observing that it had been his duty to keep the Prince Consort and the Royal Commissioners informed of all the bearings of the case, and he was instructed by his Royal Highness, who had looked over the draft report, to say that if the resolution submitted to the first meeting were passed he would assist; but at the same time he (Mr. Dilke) was commanded not to express any opinion on the part of His Royal Highness or Her Majesty, so that there might be no appearance of dictation; but after the passing of the first resolution sanctioning the scheme generally he announced that Her Majesty and His Royal Highness would give donations of £1000 and £500 respectively, that it was also proposed to place the Prince of Wales and the younger Princes and Princesses as Life Governors, and he announced that Her Royal Highness the

Princess Royal of Prussia would become a life member, and further stated that the Prince Consort would take up debentures to the extent of £1000. Such exalted patronage was regarded as a sufficient guarantee for everything, and the requisite sum of £50,000 of debenture stock was speedily forthcoming, on security which, adjudged on commercial principles, could not be regarded as satisfactory.

With the surplus proceeds of the Exhibition of 1851, the Royal Commissioners purchased about twenty-two acres of land for the purpose of erecting thereon a building for a similar exhibition in 1861; but in consequence of the disruption of European relations, and a great continental war unsettling the political balance of many friendly states, the idea of holding the Great International World's Fair was abandoned. The land was idle, and some fertile brain suggested the application of it to a grand summer and winter garden in the centre of the town residences of the nobility and gentry, yet within easy reach of the public generally, and the alliance of the Horticultural Society was sought for and obtained to the project on decidedly favourable terms to the landlords and apparently so to the Society. The former agreed to incur the expense of the architectural part and earthworks, estimated at £50,000; the Horticultural Society that of the horticultural portion of the works, raising for that purpose an equal sum. In return for this the Society to have a lease of the gardens for thirty-one years, subject to the payment of an annual rental on the following basis:—The rent to be ascertained with reference to the receipts of the Society in each year—that is to say, there should be first deducted from the sum of the gross receipts—(1) such a sum as shall be allowed by a committee in respect of expenses; and (2) the amount which may be payable by the Society for interest of any money not exceeding the sum of £50,000 borrowed by them for the works on the land. For regulating the amount to be deducted by the Society in each year for its expenses a committee was appointed of six persons, three nominated by the Commissioners and three by the Society, the chairman selected by the former, and he having "two votes in case of an equality in voting." It will thus be seen that the first charge on the receipts from the gardens was to be the current expenses of the Society, regulated and governed by the "Expenses Committee," second the interest to debenture holders, and lastly the payment of rent to the Commissioners. In the event of the Society being unable for any period of five consecutive years to pay the interest on the debenture account, the right of re-entry was claimed by the Commissioners without payment of compensation to the Society. That is an outline of the great scheme by which the Royal Commissioners succeeded in adding to the value of their and the surrounding property with the moneys of confiding debenture holders, who, under the glamour of the circumstances of the time made advances not on the gardens or freehold, but on the profits of the concern, and these, through extravagance during the early years of the union, and dissensions afterwards, failing, resulted in loss to individuals and discredit to the Society.

In 1860 everything was regarded as satisfactory. Twelve members of the Royal Family joined, and the following year the Queen granted permission for the Society to be styled the Royal Horticultural Society. As might be expected rank and fashion followed Royalty, upwards of 600 Fellows joining within six months. The Fruit and Floral Committees were transferred from St. Martin's Place, and sat for the first time at South Kensington on Shrove Tuesday, 1861. In December of the same year the Society sustained a great and irreparable loss by the death of the Prince Consort; and though the Queen expressed her wish "that the gardens should be considered as under her special patronage and protection," turbulence soon followed through extravagance, the interests of horticulture were practically ignored, and Chiswick almost entirely neglected. "Music and masquerading" perhaps fairly describes the doings of the time, as in one year £3000 were expended in

bands for the fashionable promenade. Shortly afterwards, and simultaneous with the illegal appointment of Mr. H. Cole on the Council, the horticultural representatives (Earl Ducie, Dr. Lindley, Mr. James Veitch, Mr. Robert Cooper, and Mr. John Fleming) resigned, and within about five years of the connection with South Kensington the Society had expended £73,000 in completing the garden, and was involved in a debt of £53,000, the whole of its liabilities previous to the undertaking being £4000. And even then the gardens were not finished, yet the Society was enchained to the scene of its ruin.

This Journal had no share in hastening on and cementing the alliance that is now ended. Commenting on the arrangements in 1859, it is recorded in its pages:—"We need not enter into the particulars of the scheme further than to say that it is one which the Fellows of the Society who are interested in the advancement of horticulture, and in preserving the legitimate objects for which the Society was instituted, should regard with great caution, and not allow themselves to be hurried into it without having some security and some assurance that these objects will be maintained. The decline of the Horticultural Society has been brought about by a lavish and unremunerative expenditure and mismanagement. To raise it from inanition ample funds must be provided. Believing the new movement will be productive of a considerable income, we are of opinion that if this be faithfully applied to the development of the objects originally contemplated by its founders, the Society will again take a respectable position among the great institutions of the country. But this end is not to be effected in the ornamental garden and fashionable promenade at Kensington Gore. The real working and telling effect of the Society must be carried out elsewhere; and before we give our entire and cordial support to the scheme now proposed we must have an assurance that the garden at Chiswick will be maintained in its integrity. If the Council give no such assurance the whole of the present proceedings must be regarded as nothing more than a great commercial speculation got up under the wing of the London Horticultural Society, but too little regarding the objects for which the Society was formed."

There is this difference now in the relative positions. Instead of the speculation being "under the wing" of the Society, the Royal Horticultural Society is "under the wing of the commercial speculation." Is it either dignified or advantageous for it to remain so? The Royal Horticultural Society retains its position at South Kensington by sufferance of a body, most respectable and influential, but which has no sympathy with its work or objects. It occupies the position of caretaker and nothing else, and, like all other caretakers, is liable to dismissal at a moment's notice. So long as the gardens were maintained in an attractive state, and there was in consequence a steady accession of local Fellows, there was some reason for remaining, but the gardens can never again be what they were before the inauguration of the present series of industrial exhibitions. They are practically demolished, and vast sums expended in forming and furnishing them squandered. And even the shows held on their site cannot be sustained for any length of time. That of the present season, the "Colonies," which promises to eclipse all its predecessors, may or may not be the last; but whether it is or not, it is sufficiently evident that the Royal Horticultural Society can no longer be strengthened by accessions of local Fellows. Such "supporters" who have no sympathy with the Society's objects, but have joined for the sake of local advantages, have been a source of weakness rather than strength in the past, in diverting the resources of the Society from its legitimate objects and alienating persons who are actually interested in horticultural pursuits. It is this great class to which the Society should more directly appeal, and it is a question if it would not be better to have the seat of government of the Society nearer to the commercial centre than at present. The great and rich mercantile community, as is well known to nurserymen and horticultural builders, are more than ever

disposed to share in the pleasures of gardening, and they enter with great zeal into the particular branch of the pursuit that commends itself to their taste and support.

The Royal Horticultural Society, that has now been established upwards of three-quarters of a century, should have headquarters of its own convenient both as to site and structure, and if a determined effort be made to that end the means for accomplishing it will be forthcoming when it is made known that the whole resources of the Society will be devoted to the work it was established to promote.

## PROFITABLE GARDENING.

(Continued from page 286.)

**VIOLETS.**—For the past six years I have strongly advised my friends to “go in for Violets,” and I am pleased to say those who have taken my advice are well satisfied with the result. Not only have the beds of Violets proved very remunerative, but they have also served the good purpose of finding occasional and at times daily employment for numerous men, women, and boys at a time of year when other work is not always plentiful. I am not prepared to advance any statistics, neither are they necessary for my purpose, but I can truthfully assert that it is hardly possible to grow too many, as they are extremely popular, and retailed at 1d. per bunch they usually sell rapidly. You may vary the size of bunch, or say from twelve to twenty blooms, according to the quantity of Violets available, but as a rule the price must not be advanced or they will not sell. The grower supplies the retailers at the rate of sixteen bunches to the dozen, or for 1s.—that is to say, when a dozen is ordered four bunches are given in, and this may or may not be all the profit the retailer gets over the transaction. Properly treated a few rows of Violets will usually yield an astonishing number of blooms during the winter and early spring months, while an acre or two of them will furnish enough bunches for a large town. It may be that in time there will be many grown, but according to my present experience there is plenty of room for beginners, as I find that if they cannot all be sold in our neighbourhood, there are plenty in other large towns ready to receive supplies of them.

Any ground that suits Strawberries will grow Violets equally as well, both delighting in fairly rich loamy soil. On very light loose soils it is useless to make the attempt unless its character can be changed by the addition of heavy loam or pulverised clay. If planted on rich loose ground they grow too strongly, and are not sufficiently hardy or floriferous in consequence, while the soil must be sufficiently holding or but little progress will be made, red spider being in the ascendant. The well-exposed beds are usually the hardiest, but this past winter the conditions have been reversed, and it is only those among the fruit trees from which they received some protection that have bloomed freely. Even the latter no more than paid their way, and by this it will be seen that there is a certain amount of risk to be run by those who grow Violets extensively. At present the variety known as the *Ozar* is most generally cultivated, and under good culture these grow to a good size, but in time *Victoria Regina* will replace it. Now is the time to divide and replant all Violets that have done flowering, and every strong crown properly trimmed of all runners and firmly dibbled out in good soil will soon grow to a good size. In the open fields they may be disposed 12 inches apart each way, and need not be disturbed for two years. On our strong and rather rich ground we plant them 15 inches apart each way, and these are unprofitable after the first season, consequently the whole of ours have to be replanted every year, though not necessarily in fresh positions. Where they last for two seasons half of the ground should be planted every year, or, as it happened last summer in the case of a friend who replanted the whole of his stock, a wholesale failure may result. As a rule Violets may be planted in succession to almost any crop without manure being added to the ground, but they impoverish the ground very much, and if replanted in the same position a dressing of solid manure in preference to artificial should be given. During the summer they are benefited by a mulching of either short manure, leaf soil, spent tan, short grass from the mowing machine, or even common garden soil, this being applied either before the ground has become dry or directly after a soaking rain. If no mulching is given the flat hoe must be run among them occasionally, and if the season is hot and dry an early soaking of water is necessary. In all cases all superfluous runners should be trimmed off and weeds kept down, the aim being to secure stout crowns and healthy, though not

over-luxuriant foliage. During a mild winter a continuous supply will be produced, and it must be a very bad winter if they prove unprofitable. It is almost needless to add that the blooms should be neatly, but not tightly, bunched up with two or three well-matured leaves with them.

**FRAME VIOLETS.**—In the case of open-air Violets there is, as I have shown, a certain amount of risk to be run, but with those under frames there is none at all, as the blooms are available for several months during the winter and are eagerly bought up. To show how profitable they are, I may mention that a friend recently gathered eighty-six bunches of about nine blooms or less in each from a three-light frame at one time, and took them to a town in a colliery district where he attends weekly. No one asked the price of them, but in about two hours they were quietly “collared,” and the orthodox price—viz., one penny, paid. Rather larger bunches sometimes fetch 3d. and 4d. per bunch, but those who have a quantity to dispose of are advised to sell the cheap bunches and get rid of them rapidly. The sort known hereabouts as *Marie Louise*, but which happens to be the *New York*, is most profitable in frames, and I find *Comte de Brazza's White* or *Swanley White* nearly as floriferous and, being pure white, decidedly of the most value. *De Parme* appears to be a strong grower and the blooms are larger and have longer foot-stalks than *Marie Louise*, and may eventually replace it. *King of the Violets* is a fine dark blue variety, and the rather scarce though very old *Tree Violet* produces its richly coloured blooms very freely during the winter and well into April. All these are doubles, belonging principally to the Neapolitan section, and they are much more profitable than single sorts for frame culture.

To the ground intended for double Violets we usually add a good dressing of either fine manure, old Mushroom-bed refuse, or leaf soil, this being forked into the surface in preference to digging it in freely. For the benefit of the inexperienced it should be mentioned that double Violets are not grown constantly under glass, but are prepared in the open ground, and either covered with frames or lifted and planted in pits or frames. The ground should be well worked, the position being fairly open and sunny. Strong old plants may be freely divided, every strong crown properly trimmed and dibbled out growing into a strong plant during the summer. Ours are disposed about 9 inches apart each way, at which distance they well cover the ground, and may therefore be either covered with frames or lifted and replanted in pots. They are in other respects treated similarly to the singles, though in hot positions frequent syringings benefit them, and this in order to prevent the ravages of red spider. Late in September or early in October is the time to lift or to protect, and they should be planted in good loamy soil, just clear of each other and not more than 6 inches from the glass. Shallow frames are best for covering the plants where they are grown, and failing these the plan mentioned by Mr. Oliver on page 290 is to be commended. They require plenty of light and air on all favourable occasions during the winter; indeed, unless the ventilation is well attended to they are liable to damp off wholesale. On fine bright days the lights ought to be drawn off them, care also being taken to protect from severe frosts.—I. M., *Somerset*.

## ON THE ROOT-STRUCTURE AND MODE OF GROWTH OF PRIMULACEÆ IN RELATION TO CULTIVATION.\*

[A paper prepared for the Primula Conference, April 21st, by Dr. M. T. Masters.]

FOR practical purposes it is very serviceable to consider a living plant in the light of a piece of mechanism, constructed and put together to do certain work as efficiently and as economically as circumstances permit. The comparison may serve our purpose without it being necessary to point out where it fails, and wherein lies the great difference between a machine begotten of its predecessors, and who had the like structure and endowments with itself, self-sustaining, supplying its own power from sun and air and water, built up and adapted by its own energy, and one constructed by the art of man, dependent on artificial means for its support and its power, and with no innate faculty of self-adjustment to varying circumstances. Availing ourselves, therefore, of the comparison, we may proceed to discuss what it is our machine is called on to do, how it is enabled by its conformation to do what is required of it, and, incidentally, how we may help or mar its action. The *Primulaceæ* will afford us as good illustrations of these matters as any other family of plants. It is the group which is expressly selected to furnish a text for these remarks, and which, moreover, are, as prescribed, to be limited to a part only of the machine—the root. It is permissible, however, on such an occasion to use the term root in the broad sense in which it is usually employed by gardeners, and not in the more accurate and strictly limited sense in which it is made use of by physiologists.

\* For the communication of numerous specimens illustrative of these notes I am specially indebted to Mr. Dewar of the Royal Gardens, Kew, Mr. Barron of Chiswick, Mr. Correvon of Geneva, Mr. Douglas, and other friends. For some of the drawings I have to thank Mr. Sandgren of Kew.

## THE REQUIREMENTS.

What, then, is our machine—the root—called on to do? In all cases to lay hold of the soil and secure the plant mechanically. How it does this will be sufficiently though incidentally illustrated later on, and it is not a subject on which woe cultivators need linger long. The plants we have now to deal with may be lifted out of the ground by frost, but they are hardly likely to be washed away by floods or uprooted by winds. To pot firmly and press the crown firmly into the soil in transplanting are lessons which common experience teaches, lessons which the conformation of the root to be presently noted, do but accentuate.

Another universal duty imposed on the root is to feed the plant. There is soil-food and there is air-food. The leaves, stimulated by light and heat, collect and transform the one; the roots, influenced by heat, absorb and digest the other. How they do these things is beyond the purpose of this paper to explain, but reference to any modern botanical text-book, and in particular to the truly marvellous revelations contained in the chapters on root movements in Darwin's "The Power of Movement in Plants," will supply the information and afford indications of the processes of absorption, of solution, of fermentation, of transformation, which, with or without the

Fig. 57.—Germination of *P. reticulata*.

agency of minute Bacterian organisms, constitute each root-tip, each root-hair, a laboratory and a workshop. Each root-tip, each root-hair, moreover, is as sensitive as a nerve, not only responding to a touch, but transmitting impressions from the spot touched to adjoining cells. It is as mobile as a muscle, turning towards what is useful to it, bending away from what is noxious or obstructive, threading its way through the soil, and adapting itself to circumstances as if it really possessed intelligence. It acts like the brain, says Darwin; and truly as a sentient organ, receiving and transmitting impressions and directing the course of growth and movement, it would be hard to say wherein its inferiority to the nervous system of the lower animals consists.

In the case of annual plants which live their life within the compass of a few weeks or months there is little else for the root to do than to secure the plant in the ground and to go in search of food and turn it to account when found.

But in the case of perennial plants, such as most of our Primulaceæ, another duty becomes incumbent—that of providing a store-place for water and for food. The food so stored, principally starch and allied substances, is not absorbed directly by the root and packed away, but partly by root-action and soil-food, partly by leaf-action and air-food, is manufactured in the leaves and afterwards transferred and deposited in the root or in the root-stock.

A similar formation of starch takes place in annual plants, but it is used up in process of growth or stored in the seed to be turned to use by the seedling plant when it begins life on its own account. In any case the storage requirements of an annual are small in comparison with those of a perennial. To ascertain how and in what manner the food is obtained, transformed, stored, and employed is surely to put ourselves in possession of information, of any that could be named, the most important for cultural purposes.

Another phase of work which it falls to the lot of the root (*sensu latiori*) to achieve is that of propagation, and by observing how this is effected spontaneously we may surely obtain some useful hints for our own artificial procedures.

Such, then, in very general terms, is the nature of the work to be done; such, in general outline, are the requirements of the case.

## THE MECHANISM.

In the following remarks it is proposed to give a few illustrations of the machinery by means of which the work just alluded to is done, for while the work is in all cases the same, the machinery by which that work is accomplished is manifold in detail.

## ANNUALS.

Very few cultivated Primulaceæ come under this head. Some of the *Androsaces* and *Anagallis* are annuals but speaking from a cultivator's

point of view they might be passed over if it were not for one circumstance frequently ignored or overlooked, though one of great importance—the fact that seedling plants, even of those species destined to be perennial, are, to all practical intents, annuals. Barring the slender resources stored up in the seed, the seedling plants have little store to draw upon, and thus, like the annuals, they must have good food within easy reach, and be provided with rapid means of utilising it, else they wither away.\*

*Centunculus minimus*.—A weed no cultivator would bestow a thought upon, unless it were to compass its destruction, may, nevertheless, serve as a useful illustration. It sends down into the soil a slender tap-root, which speedily ramifies just below the surface, branches and branches again till it, as it were, invades a considerable area of soil. There are no great

Fig. 58.—Root system of *P. rosea*.

"hold-fast roots—none are needed, but, on the other hand, there is a great multiplication of small fibres, and a consequent extension of absorbent surface. Notice, too, that there is no caulicle; in other words, the radicle comes straight away from beneath the two cotyledons without there being any perceptible internode (stalk) between the base of the seed-leaves and the top of the root. In a seedling Primrose may generally be observed the radicle,

Fig. 59.—*P. elatior*.

giving off branches, then an erect cylindrical portion bearing the cotyledons or seed-leaves, but sometimes reduced to very small dimensions; this is the caulicle or tigellum. Above the two seed-leaves is the plumule, consisting

"Some [seed] fell upon stony places, where they had not much earth; and forthwith they sprung up, because they had no deepness of earth; and when the sun was up they were scorched: and because they had not root, they withered away."—Matthew xiii, 5, 6.

of the first leaf or leaves above the cotyledons. In these seedlings it is curious to see how, whilst the primary roots descend vertically, the secondary ones pass off horizontally.

It is quite clear that the seed in *Centunculus* was not buried deeply, for the caulicle is a minus quantity. It is clear also the soil for such a plant should be light, open, rich, well drained. Contrast this with the germination of *Primula reticulata*, in which not only is the tigellum very long, but the two cotyledons are also raised on long, erect, or ascending stalks, as if the plant grew in the clefts of the rocks, and had a long distance to thrust its seed-leaves into the light and air (fig. 57). The requirements of seedlings are, it need hardly be said, of the same character. We all know the care that is requisite to secure the germination and the rearing of these delicate organisms.

"In the morning sow thy seed, and in the evening withhold not thine hand."  
—*Eccles. xi., 6.*

The mode of growth of the *Androsaces* is similar. They are, it is true, for the most part not annuals, but in their root-growth some of them (the caespitose species) follow the mode of annuals. The seedling plants have roots of the annual character, with a long radicle giving off numerous branches. The adult plant has little provision for storage, but consists of a dense tuft of leaves, from the axils of some of which proceed long slender runners, like those of a Strawberry, and which bear at their ends a tuft of leaves like the parent from which they sprung. From the under surface of this tuft proceed roots like those of the *Centunculus*, and, like them, destined, not for any lengthened use, but only for a temporary purpose; no long time indeed elapses ere the tuft throws out new runners and thus repeats in another generation the process of its own genesis. It would seem

Fig. 60.—*Polyanthus*.

from this peculiar mode of growth that the *Androsaces* speedily exhaust the area in which their roots spread, and having done so haste—

"To-morrow to fresh woods and pastures new,"

—Milton, *Lycidas*, l. 193.

Whether this is not an indication of value to the cultivator I leave to others who have had more experience to decide. My own want of success with these plants cannot in fairness be attributed only to neglect of the indication!

#### PERENNIALS.

In these, as for annuals, there is need for daily supplies during the growing period, and further, there is the necessity for replenishing the stores. It is necessary, therefore, to consider the root-growth of these plants from two points of view—that of food-collecting and that of food-storage.

The actual absorption of water is, of course, effected in the same way in the roots of perennials as in those of annuals, but the perennial habit allows more time wherein to work, and frequently secures a wider root-range than is possible in an annual. In a perennial, *ceteris paribus*, the roots can travel further, or penetrate deeper in search of food, than in the case of an annual.

In an annual the roots, as gardeners say, "keep at home," and there is not much necessity for a system of conduits to convey the water from its source to the stem; but in perennials it often happens that the best food supply is at some considerable distance from the stem, and the consequence is that the fibrous roots collect the liquid from the feeding-ground, and convey it in so many conduits to the stem. The thicker root-fibres have, as everyone knows, little or no power of absorption, that faculty being mostly limited to

the thinnest extremities of the root-fibres, and to the root-hairs (where present). Of course the number, length, and degree of branching of the roots depend very greatly on the physical nature of the soil in which the plant happens to be growing—

"Pinguibus hæ terris habiles, levioribus illæ."

But when due allowance is made for these circumstances each plant has more or less its own distinct character. The roots of most species of *Primula*, for instance, are very different from those of *Androsace*, and

Fig. 61.—*Alpine Auricula*.

indicate different requirements. But even in the same genus we get variations in this respect. In the common Primrose and Polyanthus, in *P. cashmiriana*, *P. capitata*, *P. amœna*, *P. Auricula*, *P. denticulata*, *P. nivalis*, *P. longiflora*, *P. cortusoides*, &c., the roots are generally rather thick and fleshy, descending more or less vertically for some little distance without branching, and then giving off short nearly horizontal branches with few root-hairs, except in *P. Auricula*, in which, in some cases at least, the roots are covered with a velvety coat of hairs. Such roots are not surface-feeders, but are capable of penetrating to a considerable depth in search of food, while their succulent habit and reserve store of water obviate the necessity for that dense network of fibrous roots that other species present. *Primula rosea* (fig. 58), *P. Kaufmanniana*, *P. involucrata*, and *P. cortusa Matthioli*, afford instances of this densely matted and comparatively superficial root development. They have few if any large root or conduit fibres; but, on the contrary, an intricate mass of fine fibrous roots, penetrating in every direction, and availing themselves, as it were, of every scrap of soil within reach. Surely we have here an indication of the necessity in cultivation of supplying these plants with ample depth and breadth of light, rich, moist, not to say wet soil. The utility of a mulch in hot dry weather is also indicated as a means of preventing the drying up of the surface roots.

In some of the *Androsaces* we find provision for keeping the roots moist and free from the risk of drought. In seedling plants of *A. elongata*, for instance, the caulicle is very long, and the slender radicle descends vertically for a long distance without branching, and then gives off near its tip a leash of much-branched fine filaments.

In *Soldanella* we have a tuft of rather thick fibres, which descend vertically into the soil, and are unbranched till near the points, where they give off numerous relatively short horizontal fibres.

#### STORAGE AND REST.

In perennials we have specially to consider the arrangements for storage of food in convenient places for use when required, and the modifications of structure associated with the periodic alternations of active growth and relative rest. Of a Primrose, whether "by a river's brim," or elsewhere, whether a yellow Primrose or one of other hue, it may be said that at one season its constant care is to increase its store, while at another its aim is to make all snug for winter. Of course the Primrose is not peculiar in these

matters, but we may perchance profit somewhat if we make use of it as an illustration of general application.

#### THE ROOT-STOCK.

The body which emits roots on the one side or beneath, and throws up leaves and flowers on the other is the "rhizome," or root-stock. It is usually subterranean, and so gets called a root, but inasmuch as it produces leaves, buds, and offsets, and has the internal structure of a stem, botanists will not admit its claim to be considered a root, for a root, under ordinary circumstances (exceptis prætermis), does none of these things. It is a development of the plumule or of the caulicle, or of both together. Usually it is more or less horizontal in its direction, as in the Primrose, in other cases it is vertical, as in the Auricula, where it thrusts itself above ground, and gives off buds or offsets in such a way that no one can mistake it for a root. Horizontal or erect, it throws down feeding-roots into the soil, and these roots are usually fleshy, serving, indeed, not only as feeders, but as storeplaces as well, thus sharing the office of the stock itself. At the free end of the stock is a bud, or a cluster of buds, by means of which the plant grows (figs. 60, 61, 62). From these buds upspring the leaves and the flowers.

#### POLARITY OF THE STOCK.

Owing to this position of the buds the stock grows at one end, and extends and pushes itself into new territory, while the other end of the stock, having yielded up its store of water and starch to the growing bud, gradually decays. Thus the plant effects very quietly and gradually a change of residence—an indication of the desirability of occasional transplantation. This progressive decay at one end suggested to old Auricula growers the "removal of the end of the Carrot," and there was nothing to be said against the process provided their surgery was confined to dead portions only, and did not include the healthy and (potentially) active roots also. In such a case the stock is put to the trouble of making new roots, which, to say the truth, it does not fail to do speedily under propitious circumstances.

The progressive growth at one end associated with progressive decay at the other, is a very marked feature in Primulaceæ. Moreover, it is often manifested in the earliest period. The root apparatus of the seedling plant seems destined for the use of the seedling only (which is thus, as before noticed, practically an annual), and when the plumule develops gradually into a permanent stem with its leaves and potential flowers, new roots are thrust out from the plumule, as may be seen in the illustrations of *Primula rotundifolia*, *P. elatior* (figs. 57, 59), and in *P. verticillata*.

The development of the tufted stem from the plumule is well exemplified in the case of the Cowslip, as pointed out to me some years since by Mr. Holland. The seedling plant germinates in the usual way, but after a time the weight of the rapidly growing plumule causes the caulicle to bend downwards and become more or less horizontal. Adventitious roots are then thrown out from the top of the original caulicle or the base of the plumule, which gradually decays, leaving the young plant independent. (Hefrey's "Elementary Course of Botany," ed. 4, p. 654.)

#### PROTECTION.

One other provision with reference to root-stock may here be noted, and that is the manner in which in most species, notably in *P. latifolia*,

Fig. 62.—Auricula.

*P. graveolens*, *P. Palinuri*, the deeply descending rhizome is protected from loss of heat, as also from mechanical injury, by the dense covering afforded by the remains of the old leaves. Contrast this state of things with the way in which Auriculas thrust themselves out of the ground, their root-stalks showing little or no trace of the leaves beyond the scar, which indicates the place whence they have fallen. It would be interesting to ascertain whether these peculiarities in the Auricula may not be connected with the development of offsets (buds) from the side of the rhizome (figs. 61, 62.)

#### TUBERS.

The tuber of a *Cyclamen* (a development originally from the tigellum) is essentially the same as the root-stock, differing only in its more or less globular form. It throws off feeding roots from its base or its sides, and it forms a bud or buds at the top. Its fleshy tissue is laden with starch and building material for new growth.

In *Trientalis*, from the caulicle or from the base of the plumule emerge long subterranean branches, which end in thickened tubers like those of *Convolvulus sepium*.

#### WINTER BUDS.

In *Primula rosea* and *P. involucrata*, *P. farinosa*, *P. rotundifolia* (herbarium spec.), and probably in many other species, we find what may be termed winter buds. In point of fact, the stock in these cases decays away almost entirely, leaving only the buds which form at its extremity or at the ends of its branches. These buds are made of dilated leafstalks densely packed one over the other, like the similar parts in a "head of Celery." They are furnished at the base with numerous root fibres, very fleshy in *P. involucrata* fibrous in *P. rosea* (fig. 58), and which serve to supply sufficient moisture in the dry season. Carefully stowed away in the centre of the leaves is the inflorescence, whose tiny pearl-like flowers may be seen securely nestling, even in midwinter, beneath their protective wraps exactly as in the case of bulbs, or Cabbages in which the leaves "turn in" well. *P. denticulata* is not so fortunate. In this plant the leaves spread widely and do not close up to cover the inflorescence, the consequence of which is the latter is apt to be stimulated by the capricious and unseasonable gleams of sun that we get in some winters, and bursts into bloom at a time when "a frost, a killing frost," is only too likely to damage the blossoms, or, if this does not happen, the flowers are liable to be rotted with wet or snow. Of course this is easily prevented by laying a Fir branch or other protection over the plant.

The formation of a thick root-stock of tubers, of fleshy roots, or of large winter buds, may all be taken as indicative that the plant is thrifty enough to lay by a provision for the future, and, moreover, that it adapts itself to falling temperature and other untoward circumstances, and goes to rest. To afford such rest in our uncertain climate is, as all gardeners know, occasionally a difficult matter. In my own experience, which, if personally small, is vicariously large, I find much virtue in a covering of Fern, straw, or a Fir branch.

The foregoing remarks apply to plants growing in the open air or with no other protection than a cold frame in winter. Under glass the requirements are somewhat different, and the conditions likewise. The plant is grown for some special purpose, and the gardener considers not so much the natural "habit" of the plant under normal circumstances and the way in which he may promote its welfare, as the manner in which he can induce it to adapt itself to his requirements and the conditions he offers. He may even find it requisite or advantageous to invert the natural course of things—to force when the plant, left to itself, would go to rest, to check growth when the natural tendency would be to progress. For instance, the formation of the *Cyclamen* tuber is an indication that the plant under natural circumstances has a season of rest; and before *Cyclamen* culture had reached such a pitch of perfection as it has now attained growers were wont to give the tubers an enforced rest by drying them off. Now that practice is quite reversed; and that such an amount of rest as the old growers gave the plant is not necessary under artificial conditions is shown by the fact that the foliage of the *Cyclamen* is persistent, and no deficiency of food to sustain this prolonged season of growth is to be feared, for food the gardener can give freely and at times when Nature herself might close her stores. This justifies the treatment of the *Cyclamen* as if it were a bulb with evergreen foliage.

Servile imitation of Nature—such imitation, that is, as we can compass!—is, to say the least, not very much better than mechanical routine. The wisdom of the gardener is shown first in his knowledge of plants, and next in the skill and judgment which he brings to bear in inducing or helping the plant to adapt itself to unnatural conditions, and to the fulfilment of artificial requirements.

Whether from the point of view of the physiologist or from that of the cultivator, a thorough study of the life-history of plants is absolutely essential to complete success. It is not given to any to reach the highest standard, but it is a satisfaction to know that every step in the way is a real gain—a link in the chain of true progress—a progress which, at least as far as the community at large is concerned, knows no countermarch.

#### A SYNOPSIS OF THE EUROPEAN SPECIES OF PRIMULA, WITH THEIR DISTRIBUTION.

[A paper prepared for the Primula Conference by Mr. J. G. Baker.]

GROUP I. PRIMULASTRA.—Young leaves revolute, never mealy beneath. Calyx strongly ribbed. Flowers yellow.

1, *P. VULGARIS*, *Huds.* (Primrose).—Leaves narrowed gradually to the base. Umbel sessile; pedicels long. Calyx-teeth lanceolate. Corolla-limb large, pale yellow.—Distrib.: Throughout Europe, except the Mediterranean region.

2, *P. ELATIOR*, *Jacq.* (true Oxlip).—Leaves narrowed gradually to the base. Peduncles produced; pedicels short. Calyx-teeth lanceolate. Corolla-limb large, pale yellow; throat not plicate.—Distrib.: Throughout Europe, except the Mediterranean region. Differs from the hybrid Oxlip by its more villous calyx and paler corolla, not plicate at the throat.

3, *P. OFFICINALIS*, *Scop.* (Cowslip).—Leaves narrowed suddenly at the base to a winged petiole. Peduncles produced; pedicels short. Calyx-teeth deltoid. Corolla-limb smaller, deeper yellow; throat plicate.—Distrib.: Throughout Europe; rare and not typical in the Mediterranean region.

Group II. ALEURITIA.—Leaves often mealy beneath, revolute when young. Calyx not ribbed. Flowers lilac.

4, *P. FARINOSA*, *Linn.*—Leaves small, crenulate, mealy below. Pedicels and calyx also mealy. Caly-tube campanulate; teeth as long as tube. Corolla-tube short.—Distrib.: Northern and Central Europe, mountains of Spain

5, *P. STRICTA*, *Hornem.*—Differs from *farinosa* by leaves not mealy beneath, pedicels and calyx not mealy, flowers fewer.—Distrib.: Mountains of Scandinavia and Northern Russia.

6, *P. SIBIRICA*, *Jacq.*, VAR. *FINMARCHICA*, *Jacq.*—Leaves broader than in *farinosa*, entire, not mealy beneath. Pedicels longer. Calyx-tube oblong; teeth much shorter than the tube. Corolla-tube short. Flowers few.—Distrib.: Mountains of Scandinavia. The type known in Siberia only.

7, *P. FRONDOSA*, *Janka.*—Leaves large, thin, not mealy beneath. Calyx-tube campanulate; teeth lanceolate-deltoid, as long as the tube. Corolla-tube short.—Distrib.: Mountains of Thrace. Very rare.

8, *P. LONGIFLORA*, *All.*—Leaf like that of *farinosa*, usually mealy beneath. Calyx longer, both tube and teeth. Corolla-tube 1 inch or more long. Corolla-limb  $\frac{1}{2}$ — $\frac{3}{4}$  inch in diameter.—Distrib.: Mountains of Central Europe.

Group III.—*AURICULASTRA*.—Young leaves involute. Calyx short, both tube and teeth.

\* *True Auriculastra*.—Leaves, calyx and pedicels not viscose.

9, *P. AURICULA*, *Linn.*—Leaves large, entire or minutely toothed. Leaves beneath, pedicels and calyx mealy. Bracts small. Flower pale yellow.—Distrib.: Mountains of Central Europe.

10, *P. PALINURI*, *Petag.*—Differs mainly from the large forms of *Auricula* by its constantly inciso-crenate leaves and larger foliaceous bracts. Flower pale yellow.—Distrib.: Promontory of Palinurus, Naples.

11, *P. MARGINATA*, *Curt.*—Much dwarfer than *Auricula*, with strongly inciso-crenate leaves with a white mealy margin. Flowers fewer, lilac.—Distrib.: Alps of Dauphine and Piedmont.

12, *P. CARNIOLICA*, *Jacq.*—Leaves oblong, thin, entire, not at all mealy. Flowers lilac.—Distrib.: Alps of Austria and Lombardy.

\*\* *Erythrodosa*.—Leaves, pedicels, and calyx viscose.

13, *P. VISCOSA*, *Vill.*—Leaves obovate, strongly inciso-crenate. Pedicels twice as long as calyx. Calyx-teeth nearly as long as the tube. Flowers few or many, lilac.—Distrib.: Pyrenees and mountains of Central Europe. Many varieties (*villosa*, *Wulf.*, *latifolia*, *Lap.*, &c.).

14, *P. DAONENSIS*, *Leyb.*—Differs from dwarf few-flowered forms of *viscosa* by its narrower leaves, shorter pedicels and much smaller calyx, with very small obtuse teeth.—Distrib.: Granitic Alps of Switzerland and Austria.

Group IV.—*ARTHITICA*.—Young leaves involute; calyx long; tube cylindrical or infundibuliform. Flowers always lilac.

\* Corolla lobes shallowly bifid.

15, *P. CALYCINA*, *Duby.*—Leaves large, entire, acute, with a distinct white, mealy edge. Bracts large, linear. Calyx  $\frac{1}{2}$  inch long; teeth lanceolate, as long as tube.—Distrib.: Alps of Lombardy.

16, *P. SPECTABILIS*, *Tratt.*—Leaves large, entire, obtuse or subacute, with an indistinct pale edge. Bracts smaller than in the last.—Calyx  $\frac{1}{4}$ — $\frac{1}{2}$  inch long; teeth much shorter than the tube.—Distrib.: Alps of Central Europe; several varieties: was included by Linnaeus under *integrifolia*.

17, *P. INTEGRIFOLIA*, *Linn.*, ex parte.—Dwarfer than *spectabilis*, with smaller leaves and only 1—3 flowers.—Distrib.: Pyrenees and mountains of Switzerland and Lombardy.

18, *P. ALLIONI*, *Lois.*—Dwarf, 1—2-flowered, with very short peduncle and pedicels. Leaves obovate, very obtuse, sub-entire, viscose.—Distrib.: Alps of Piedmont, very rare; and a geographical variety (*P. tyrolensis*, *Schott*) in the Tyrol.

\*\* Corolla-lobes deeply bifid.

19, *P. MINIMA*, *Linn.*—Very dwarf; leaves small, obtuse, sharply toothed, not viscose; flowers 1—2; peduncle and pedicels both very short. Distrib.: Mountains of Switzerland, North Italy, Austria, and Turkey.

20, *P. GLUTINOSA*, *Wulf.*—Leaves obtuse, denticulate, viscose. Flowers many, in a dense umbel, with an elongated peduncle, and large oblong obtuse bracts; pedicels absent.—Distrib.: Mountains of the Engadine, Lombardy and Austria.

### MILDEW ON STRAWBERRIES.

I GROW a great quantity of Strawberries under glass thus. I make temporary frames for 6-feet by 4-feet lights to rest on, thus covering three rows of plants at 2 feet apart, planted in the open ground. The sides are formed with either hoards or sacks. I get ripe Strawberries under these lights from eighteen to twenty days earlier than from the plants not covered. Plenty of good fine fruits in both cases, only those outside are free from mildew and the others are not. All goes well until the fruits begin colouring. The front and back rows are the worst, and the middle one the least mildewed. I think the cause of it is the cold nights, for in May last year the pits were often at 90° in the day with abundance of ventilation, and at 5.30 A.M. at 41°. I have left air on some all night, others quite close, without different results. Shading is used a few hours in bright weather after they begin to colour, as I find the fruit will not stand too much sun under glass. A friend of mine called last May, and, asking him if he could suggest a remedy, he said, if I were to run a hot-water pipe round them I should remedy it, but that is not practicable in my case. Much has been said in the Journal about mildew on Roses, I should like Mr. Bardney's opinion about mildew on Strawberries. Could I apply any mixture with the syringe that would not be injurious to the fruit while they were green? If you could help me through your valuable Journal you would confer a great boon on Strawberry growers besides myself.—A READER.

[The cause of mildew in this case is due, not only to the great irregularity between the day and night temperature they are subjected to, but the manner in which they are ventilated. The difference between the day and night temperatures is so great that this combined with a somewhat confined atmosphere is almost certain to produce mildew. Supposing that no cold draughts strike through the boards or sacks used, those rows

towards the outer portions of the frame are subjected at night to a much lower temperature both of the soil and atmosphere than those in the centre. This may to a very large extent be prevented by covering the frame at night with some close material that will prevent radiation; not only the glass but the sides should be covered. I have no doubt that the plants in the morning are covered with dew, which is due to the lowering of the temperature, and if this is not evaporated by early ventilation it adds to the evil. The ventilation of the frame probably consists in drawing up and down the lights alternately during bright sunshine, and if this is the case I am not surprised that the outer row plants have become a prey to mildew. When frames are ventilated on this principle the plants near the front and back practically receive no air, in fact it does not circulate freely amongst and below the foliage. To remedy this, provision should be made for the admission of air freely during favourable weather both to the back and front of the frame on a level with the soil. If this were done there would be very little need for tilting the lights or drawing them up and down without the day proved exceptionally hot; but it would be found that air would circulate freely amongst the plants and they would remain perfectly free from mildew provided cold draughts were avoided, the frame ventilated early and closed early to husband sun heat, so that the night temperature could be maintained as high as possible. I have never found Strawberries prove a great success in frames that have only had provision for ventilating above them instead of below or on a level with the plants. The same remarks apply with equal force to the majority of hardy plants cultivated in such frames.

I have never tried my softsoap solution that I use for Roses on Strawberries, but if your correspondent's plants are attacked with mildew he might try it on a few of them and record the result. I have destroyed mildew on the foliage of plants in autumn by a solution of softsoap and water, using 1 oz. of the former to 1 gallon of the latter, with a good handful of sulphur stirred into each 4 gallons, and then the plants syringed with it. But this would not be practicable when the plants were bearing fruit. Prevention is better than cure, but if the plants are attacked I cannot tender better advice than that given in your last issue, page 308.—WM. BARDNEY.]

### HEDGES.

ON page 297, April 15th, of this Journal I read Mr. R. Inglis's article on the management of hedges, and think his remarks are rather misleading. I do not agree with him in siding up a hedge as represented in fig. 53 A when it has got out of shape or thin and bare at the bottom. Siding it up will not fill the gap, nor will it make a good bottom. The best and cheapest way to make a good fence of an old neglected hedge is to have it plashed and the growths laid. You can in that way stop all gaps with live wood, and get a good bottom. Our method is to get 4 foot stakes, drive them 1 foot in the ground as the work of laying proceeds, cutting all the oldest hard wood out close to the ground, selecting all the youngest wood for laying-in; these to be cut half through close to the ground, then pressed down between the stakes not too thickly; run a binder on the top of the stakes, and you will then have a hedge about 3 feet high. After that let the hedge grow upright for two years, only cutting in the side growths. In the autumn of the second year cut the hedge in the shape represented in fig. 53 C of the Journal, page 297, April 15th—that is, narrow at the top. This is the best way to keep a good thick bottom; the layers make a sort of network as the young growth from the old stools come up between them, and all is then interwoven together, and is much stronger than hedges only topped or sided up. Hedges that have not been layed rarely or ever have a good base. It is a great mistake not to have every young quick fence layed before it is topped. Many young quick hedges are much checked in their growth by being cut in every year, and some twice a year.

Mr. R. Inglis says he has seen young hedges left four or five years to grow without cutting to give them strength, and then had them cut down; this he thinks is most foolish. We grow all our young hedges four and five, and sometimes six years, then they are layed as referred to above, and have the same treatment the first two years after. I also venture to say that a young hedge to grow four or five years without a check and he then cut down will make a far stronger and better fence than the one always kept clipped from the first year it is planted. The frequent clipping is a great check to the roots, which is reduced by frequent clipping as well as the head. We know hedges that have been clipped a number of years often get very wide, and some thin at the bottom. When our hedges that have been layed get too wide we side them up on one side close to the layers, then two years after trim up the other side as close as the former.

Should there be any bare places in the bottom when siding the hedge up cut a few notches in the stools that are bare. This will generally cause the stools to break out below the notches, which will fill up the bare places with young wood. I have often seen gaps stopped with brambles or any rubbish, pressing it close in, thus making larger gaps every year by smothering all young growth under the hrambles. Our plan is to have some thin larch poles sawn down into rails, and in each gap we put one long rail, so that it is a few feet longer than the gap, and each end is pushed into the middle of the hedge above and below the gap about 1 foot from the top of the hedge. We then select the shorter hars and saw them up to stakes or poles, and these we drive into the ground in the middle of the hedge and nail them to the long bar, leaving the pales about 1 foot above the bar; that makes the pales about the same height as the hedge. The paling should not be too thick or too close together, and always worked

in the middle of the hedge. This I find is the best way to get weakly places and gaps filled. Nor do I think wide or square top hedges look well, especially for a farm. We have our hedges trimmed as at fig. 53, C, on page 297, and only trim them once a year—that is, the farm hedges. We generally commence cutting the end of September or the beginning of October, and have them done by piece work—that is 4d. a chain of 22 yards, including cleaning up the rubbish and leaving it in heaps. Should the hedge be full of grass at the bottom, we give 1d. more per chain—that is, 5d. per chain. We have our hedges sided up with the hedge knife, or, as some call it, hedge-topper, and always have all the hedges cut upwards. A good workman will cut through at every stroke and make his work look as even as many will with the shears.—BAILIFF AND GARDENER.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 287.)

### SINGLE VARIETIES.

SINGLE Chrysanthemums are not grown nearly so much as their merits deserve, seeing how useful the flowers are for the decoration of vases, mixing so well as they do with Fern or other greenery. Now that the varieties are becoming numerous and the colours more varied a larger demand for plants is sure to take place. They bloom very profusely, and the flowers last a long time either on the plants or in a cut state. They do not require so much space or pot room as those of the larger sections. They have not been much seen at exhibitions owing to a want of variety in colour perhaps, and to the fact that the general style of growing Chrysanthemums for exhibition—viz., a few flowers on a plant to obtain size, is not the best suited for the growth of single varieties. Blooming in masses is the way they show to the best advantage. They are extremely useful when grown to flower later than the ordinary kinds, and are well adapted for growing in a dwarf state for room-decoration in vases; or even as dinner-table plants they are appreciated by some, and the bright-coloured varieties make an agreeable change during the dull season of winter.

The most effective method of cultivating them is growing the plants in bush form similar to that previously described, the cultural notes given under that heading applying equally well to the single varieties. Long spikes branching freely in a natural manner produce flowers in abundance; but where large individual blooms are required the system of growing Pompons for large blooms is specially recommended.

For the production of small plants suitable for vases the following details should be observed. Plant old or young plants on an open space of ground, putting out those struck in January about the middle of May, tying the stems firmly as they grow to stakes to prevent breakage by wind or other accident. Do not top the shoots, but allow them to grow uninterrupted, but in the case of the old plants thin the stems to say six on each; if more spring from the base remove them. Early in September, when the bloom buds are forming, take off the points of the shoots about 8 inches long, insert them in pots, say five cuttings in a  $4\frac{1}{2}$ -inch, and nine in a 6-inch pot, using sandy soil with a free admixture of leaf mould, and give a good watering to settle them firmly in the soil. If the cuttings are not taken off the plants till the flower buds attain a good size they do not root so quickly, and consequently the leaves flag more when they are taken from the hotbed, for they require a gentle heat with shade to prevent loss of foliage. Sprinkle with tepid water every day in fine weather until they are rooted, then gradually harden off and place in a cool house as near to the glass as possible to keep them sturdy. Each plant will produce several flower buds; if the side ones are removed, retaining only the one at the extreme point of the shoot, this flower will be much larger than if all were allowed to grow. Appended is a list of some varieties to be recommended for growing:—Terra Cotta, Patience, Oscar Wilde, Charley Davis, Mary Anderson, Canariensis Improved, Mrs. Langtry, Mrs. J. Wills, Elsie Maud, Grace Darling, Miss Lulu Martin, Miss Davis, White Perfection, Oriflamme, Mrs. Deane, Gus Harris, Miss Ellen Terry.

### SUMMER CHRYSANTHEMUMS.

With the advent of what are termed summer Chrysanthemums the season has been prolonged to a large extent; still it must be admitted that varieties which bloom so early in the season are not so much appreciated as those which are in season later when other flowers are scarce. Good blooms of some of the best sorts are desirable and well repay any trouble bestowed upon them. Particularly are they appreciated for the decoration of churches, for harvest thanksgivings where white flowers are always in demand. For conservatory decoration there is still a want of that variety of colour which is found in the larger sections. For herbaceous and shrubby decoration they are extremely useful, their habit of growth being in most cases compact, and as they bloom freely they

render the borders where they are employed attractive at a season when many occupants of herbaceous borders are past their best. Good varieties for planting in the borders are Nanum, blush white, very free; La Petite Marie, white with yellow tint, very dwarf; Lyon, purple; Flora, yellow; Madame Jolivart, white; Mr. W. Piercy, red changing to bronze brown; Anastasio, magenta, very free; Fiberta, yellow; Frederick Marronet, bronze; Mons. Pynaert Van Geert, Japanese, yellow striped bright red; Isidore Feral, rosy lilac and golden centre; Madame Piccol, rosy purple; and Salter's Early Blush, tender rose. Cuttings should be struck in February, topped twice, potted in  $4\frac{1}{2}$ -inch pots, grown in a cold frame, kept sturdy, and planted out in May, when no danger of frost need be apprehended. Water the plants freely during dry weather in summer, tie the branches neatly to stakes as growth proceeds to prevent them being broken by wind, and allow them to bloom as freely as they will. The following are some of the best sorts for blooming in pots in September and early in October:—Madame Desgrange, large white; La Vierge, white; Mrs. Cullingford, white; C. Wermig, a primrose yellow sport from Madame Desgrange. Cuttings should be rooted in January in the ordinary way, topped once when 4 inches high, and allowed to grow with three stems, when they will branch again, this time selecting three additional branches for Madame Desgrange and its sport. The other sorts may have about ten branches in all. If these are allowed to produce one bloom each the quality of the flowers will be good, providing other wants have been attended to, such as potting as required, at last into 9-inch pots, careful watering and disbudding the flowers; but if more flowers in number are preferred allow extra branches to grow from the natural break.

### VARIETIES FOR WALLS AND BORDERS.

By following out a few simple cultural instructions many spaces of otherwise bleak walls may be made to look gay, and provided the weather is not too wet or frosty blooms can be cut that would put to shame not a few that are grown under more favourable circumstances, and staged at some of the leading shows. The main point is to grow suitable varieties. The reflexed section are best adapted for walls, for owing to the imbrication of their florets the water does not lodge among them so much. Next in merit come the reflexed varieties of Japanese and Pompons, which on account of their floriferous habit make a good show. Single varieties are also suitable, blooming freely and lasting in good condition a long time. A southern aspect is the best position for the plants, and if there is a wide coping on the wall so much the better, as this in a measure prevents the blooms becoming so wet as they otherwise would be owing to drip from the wall. If the wall is 5 or 7 feet high it will be an advantage, as larger flowers and more in quantity can be produced than on a wall not so high. We will presume then that the wall is 7 feet high, and large blooms and a quantity of smaller ones are wished for. Procure early in April a sufficient number of plants which have bloomed in pots the year previously; these are better than young ones from cuttings of the current year owing to the extra number of shoots produced at the base, and are better furnished with branches to begin with. Remove part of the old soil from the roots and plant them close to the wall at a distance of 3 feet apart. If the soil is fairly good add some manure. Should the soil be of a poor character it is better to replace it with some composed of loam three parts, and two parts of manure. Between each two large-flowered varieties plant one Pompon, which will cover the bottom part of the wall; tread the soil firmly about the plants, and when they begin to grow water them freely. If the plants were of good size the previous year they will start into growth with many shoots. Select four of the strongest on each plant, removing all the others except the Pompons, which may have six growths. When the branches are long enough spread them out thinly and fasten to the wall with shreds and nails, continually securing them as growth proceeds. Do not top the branches. When the first break takes place select two of the strongest shoots on each original stem, or more if space will allow; some kinds requiring less space than others owing to the length of their foliage, taking off the remainder. From 4 to 6 inches apart is a suitable distance to train them from each other. Buds will be formed at the point of each shoot toward the end of August. The number required must now be determined, as one flower to each stem is all that can be depended upon when size is the leading question. It is wise to allow about three stems on each plant to produce a single bud, and from all other shoots remove the flower buds, allowing the plants to make another natural break. The result of this will be an increase of the branches and a production of a large number of blooms, as these new shoots will not require disbudding.

As soon as the roots have taken possession of the new soil apply liquid manure in a weak state. The drainings from the manure yard are very good for the purpose, increasing the strength when

the bloom buds are formed. After a hot day thoroughly syringe the plants, this greatly assisting in keeping the foliage clean and in a healthy condition. If the wall is lower and large blooms are required the method of training the plants must be altered, and planting should be done in the same way, except that the Pompons must be dispensed with and the other plants placed 2 feet 6 inches apart. In securing the stems to the wall train them in a slanting direction across one another; by this means long branches can be accommodated without their extending beyond the top of the wall. Thin the branches at the breaks, and select the buds as previously described; but where quantity of flowers is the main object, and the wall not so high, top the plants when about 6 inches long, and continue this topping till the end of June, laying in the shoots as space will allow. As showing the time flowers last upon plants grown at the foot of walls under the method described, at Swanmore Park they commenced to bloom on October 1st, 1885, and continued to do so till the 10th of December, when a severe frost coming quickly after rain put an end to them. In favourable seasons Chrysanthemums bloom freely when planted in the herbaceous or shrubby borders, planting them according to the natural height of growth of each kind; but I do not strongly recommend this system, as a wet autumn spoils the blooms by damping, and a sharp frost in November disfigures them beyond recovery. Pompon and small-blooming varieties of Japanese and Incurved are the best for borders.

I append the names of some of the sorts I have found succeed for walls, and no doubt there are many others equally well adapted for the purpose. *Reflexed*.—Golden Christine, Pink Christine, Mrs. Forsyth, King of Crimson, Phidias, Progne. *Incurved*.—Refulgence, Golden Empress, Lord Alcester, Mrs. G. Rundle, Mrs. Dixon, George Glenny, Pink Venus, Othello, Jardin des Plantes. *Singles*.—Oscar Wilde, Patience. *Japanese*.—Dr. Macary, Bouquet Fait, Peter the Great, Elaine, Tendresse, Mons. Mousillac, Margot, Mdlle. Lacroix, Harlequin, George Gordon, L'Incomparable, The Daimio. *Pompons*.—White Trevenna, Snowdrop, Golden Circle, Nelly Rainford, Rosinante, St. Michael.—E. MOLYNEUX.

At a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Dr. Maxwell T. Masters in the chair, the following candidates were unanimously elected Fellows—viz., Mrs. Henry Day, Edward Fyson, Mrs. Garbutt, Mrs. Lewin, H. G. Lindesay, S. Nicholls, A. D. Robertson, Fred. H. Smith.

— WE are informed by the Secretaries of the NATIONAL ROSE SOCIETY that arrangements have been made by the Royal Caledonian Horticultural Society to hold the Provincial Exhibition for 1887 in Edinburgh in the second week of July.

— "T.W.G." writes: "Has not 'D., Deal' (on p. 317) made a slip of the pen in calling 'TEA ROSE SUNSET' a sport from 'Etoile de Lyon'? 'Perle des Jardins' is the parent given in Peter Henderson's circular, and generally quoted. Gloire Lyonnaise is not very yellow certainly, though its base is just yellow enough 'to swear by;' but it is a pretty Rose—more like Lamarque than any other variety that occurs to me—and it was well shown by Messrs. Paul of Cheshunt, at South Kensington on the 20th inst., so that it would probably make a good pot Rose. Is not Mr. Mawley (p. 321) perpetuating an error in giving the date of the Hereford Rose Show as July 8th? I understood it had been postponed to Friday, July 9th.

— THE TAUNTON DEANE HORTICULTURAL AND FLORICULTURAL SOCIETY will hold their nineteenth annual Show at Vивиary Park, Taunton, on Thursday, August 12th, 1886. The schedule of prizes enumerates 146 classes, in some of which the prizes are very liberal. One of the principal is that for twelve stove and greenhouse plants in flower, the prizes being £20, £12 10s., and £7 10s. The Hon Secretaries are Messrs. Howard Maynard and Alex. Hammett, 5, Hammett Street, Taunton.

— AN Edinburgh correspondent sends us a box of large and bright CHRYSANTHEMUM SEGETUM BLOOMS, and remarks that he has some plants which have flowered most of the winter, and seem as if they would continue all the summer. The blooms sent are from two different plants.

The small flowers are making an attempt to become double. "Like all Chrysanthemums, they keep a long time fresh when cut. I have some in water that was cut a fortnight ago, and they are as fresh-looking as the day they were cut. In the West of Scotland it is found growing freely amongst the corn as an annual. I am trying some experiments with it, and would like to cross it with some of the single Chinese Chrysanthemums."

— "T. N. R." writes:—"In the large conservatory at the Botanical Gardens, Manchester, RHODODENDRON FALCONERI is now flowering. The plant is under 7 feet high, bearing five huge clusters of whitish flowers, which surmount its handsome foliage, producing a distinct and attractive appearance. Hitherto I have been under the impression that R. Falconeri assumed considerable size ere it evinced a tendency to bloom. If any reader of the *Journal of Horticulture* has succeeded in flowering this species it would be interesting to know what dimensions the plant has attained when flower buds were formed."

— How admirably Orchids are adapted for small town gardens is well exemplified by DR. DUKE'S COLLECTION AT LEWISHAM. Five years ago a dozen plants were commenced with in a house 10 feet by 8; now 4000 plants are accommodated in seven or eight structures. The entire garden does not exceed the eighth of an acre, yet there is a good-sized lawn, mounds of Daffodils, a Fern bank, besides the Orchid houses. These are packed with plants in a manner seldom seen, nearly as many being suspended from the roofs as are arranged on the stages below them. In one narrow span-roofed structure is quite a wall of charming flowers from the stage to the glass. We had merely a twilight glance, and took no names, but saw sufficient to assure us that Dr. Duke has some gems in his collection, and that he is a devoted admirer and skilful grower of this beautiful family of plants. Dr. Duke's residence is within five minutes' walk of Lewisham Junction, and his multum in parvo garden is worthy of inspection and merits further notice than can be accorded in our present issue.

— MR. B. COWAN sends the following note:—"At Pilmore Hall, the seat of E. Backhouse, Esq., in one of the plant stoves is a fine plant of the old CALANTHE VERATRIFOLIA with three spikes. The glass structures are of great extent. In the conservatory is a Chamaerops Fortunei throwing up four spikes, a magnificent Countess of Haddington Rhododendron, a fine Acacia verticillata, which hangs down gracefully, and the contrast is most pleasing. Azaleas were well flowered and plenty of them, while in the outside border Iris reticulata was blooming profusely. The gardener, Mr. Simpson, has every department in excellent order."

— WE have received a copy of the Official Guide to the COLLECTION OF TIMBERS IN THE MUSEUMS OF ECONOMIC BOTANY, ROYAL GARDENS, KEW, which forms the third of the series being issued from this establishment. It comprises eighty pages of closely printed matter, giving many interesting particulars concerning the principal home and foreign timbers employed in commerce, with brief descriptions of the dimensions the trees attain, their uses, general character of the wood, local and scientific names. Accompanying the guide is an excellent route map of the Royal Gardens, mounted on linen and coloured. This and the guide are sold separately at the nominal price of 2d. each.

— AS an example of the style adopted in the above-mentioned Guide, we extract the following note on the TEAK, TECTONA GRANDIS. "A large tree of India, Java, Sumatra, and the Malay Islands. It is the chief timber of India and Burma, and is largely exported for ship-building and railway carriages. In India it is used for similar purposes, as well as for bridges, sleepers, furniture, &c. Teak is very durable, and when once properly seasoned does not split or warp. It is said not to suffer when in contact with iron, and is rarely, if ever, attacked by white ants. This durability is said to be due to the presence of an aromatic oil, which is extracted from the wood in Burmah, and is used medicinally as a substitute for linseed oil and as a varnish."

— A COMMON but pretty plant for shrubbery or other shaded borders is ANEMONE NEMOROSA, the Wood Anemone, with its double white and other varieties. They are now flowering freely, and have a charming appearance dotted about amongst the shrubs in company with Corydalis bulbosa, Primroses, and Violets. If cut with a good length of stalk below the leaves the Wood Anemones last well in water arranged with other flowers.

— MR. J. WYATT, The Gardens, Bradenhurst, Caterham Valley,

sends us an extremely fine sample of MUSHROOMS, which he observes were "from a bed that has come into bearing very quickly. It was made underneath the stage of a warm greenhouse, spawned on March 17th with spawn I found in an exhausted hotbed. I gathered the first dish on April 14th, and at the present time the bed is almost covered with Mushrooms. I also send one of a very curious growth, which I thought might interest you."

— F. J. states that "QUEEN WASPS are very numerous this spring. Fifty-one were killed to-day and five yesterday, several more escaped. All of them were killed among the Gooseberry trees, which are now in flower."

— GARDENING APPOINTMENTS.—Mr. E. Hunt, late foreman to Mr. Milford, Westree Hall Gardens, has been appointed gardener to Rowland Cotton, Esq., Etwall Hall, Derby; and Mr. W. Thorpe of Allestree Hall, gardener to — Samuda, Esq., Shipton Court, Chipping Norton, Oxfordshire.

— ONE of the most beautiful because informal arrangements of plants and flowers we have recently had the pleasure of inspecting is in Mr. LARKING'S WINTER GARDEN at The Firs, Lee, Kent. The structure is large enough for the formation of large irregular mounds of soil and undulating borders, and in these Azaleas with other flowering and fine-foliage plants are plunged, forming large free banks, interspersed by twisting gravel paths. The effect produced reminds us somewhat of a Belgian Flower Show in miniature, and it far excels any arrangement that can be produced in straight lines and on elevated stages. Particularly fine near the margins of the borders are several plants of *Primula obconica*; these, and in fact everything else in the structure, afford sufficient evidence of the cultural skill and taste displayed by the gardener, Mr. T. W. Sanders. If we mistake not, a useful lesson in Vine pruning will be afforded at The Firs during the current season, a full crop of Grapes succeeding a light one on very old Vines by a change in the system of pruning.

— DENDROBIUM NOBILE.—Mr. C. Prinsep sends us the following note with specimens referred to:—"Herewith I send you two growths of *D. nobile* taken from the plants I had in London last year, by which you will be able to judge how much the plants have deteriorated. You will notice that the longest pseudo-bulb has flowered from fifteen nodes; from fourteen of the nodes each raceme contains three flowers, the other one has four blooms on it, making in all forty-six flowers on the one growth. The other growth you will notice has nearly all four flowers on a raceme, and no raceme with less than three flowers on. One of the growths had five flowers on a raceme, which is the largest number I have seen of *D. nobile*. Having had to cut some hundreds of flowers of *D. nobile* this last three weeks to send away, I find cutting the growths with the flowers on them to be far preferable to those that have no growths attached to them. I send a spike of bloom of *D. densiflorum* taken from a growth made last year which had two such spikes on." The specimens received are splendid. We have seen none that surpassed them, and few equal in merit from either pruned or unpruned plants. They represent, not deterioration, but invigoration, for they excel those produced by the plants last year.

— THE "American Gardeners' Monthly" has the following on "UTILISING THE EARTH'S HEAT.—Natural gas has been utilised, and there seems some chance to heat our greenhouses by natural heat. It is now tolerably certain that instead of fifty miles, the molten portion of the earth may be reached at ten. At Pesch in Hungary, a bore 951 metres finds the water 161°. In some of our Colorado mines taken horizontally into the mountain sides the heat is so unbearable that men can scarcely work."

— FRESH ANTIPODEAN FRUIT FOR THE LONDON MARKET.—The experiment of shipping fresh fruits to the English market is likely to be thoroughly tested during the Indian and Colonial Exhibition to be opened in London in May next. By request of the Victorian Commissioners the whole arrangements for securing and shipping the fruit have been undertaken by the Royal Horticultural Society, and in response to a circular sent out the growers have sent in some very fine samples. The first shipment left by the "John Elder" a fortnight ago, and comprised over eighty cases, including Apples, Pears, and Grapes. The second shipment leaves to-day per steamer "Austral," and will consist of over 200 cases of Apples, Grapes, Filberts, Pears, and Tomatoes. All parts of

the Colony will be represented in these collections, as Gippsland, Goulburn Valley, Warrnambool, Sandhurst, Echuca, Yan Yean, and districts round Melbourne have responded in a liberal manner. One grower alone has forwarded seventy cases of Apples and Pears. Every care has been taken in picking and packing the fruit. Mr. C. Neilson, the Curator of the Royal Horticultural Society's Gardens, Richmond, personally superintends each shipment, and any grower desirous of full information will be supplied on application to him. The whole cost of freight, &c., is borne by the Indian and Colonial Exhibition. The fruit is exhibited in the name of the growers, and sold in London on their account. The next shipment will leave per "Cuzco" on April 2nd, to be followed by four other collections of about four tons each.—(*Melbourne Age*.)

#### SPRING TREATMENT OF MAIDENHAIR FERNS.

THERE are few Ferns more generally grown than the Maidenhair, *Adiantum cuneatum*. It is one of the first to be selected by anyone beginning to grow plants in a glass house. In large gardens it is grown by the score, and those who have no garden, but make the most of their windows, always try to grow the Maidenhair. Two or three years ago in taking some plants to a charitable bazaar, I found that the Maidenhair Ferns were the greatest in demand; they were sold first and realised double the money of any other plants, but it is not surprising that they should be such favourites, as they are so beautiful and delicate in form, pleasing in colour, and above all useful for all kinds of decorations.

Those who have grown them well for years and know their value and treatment, need not read this note, but I find many who have only begun their culture and others who never fully understood it have much difficulty in knowing how to treat them in spring. As a rule they become shabby in autumn or by midwinter, and if not properly treated traces of this may remain throughout the whole of the following season. When the old fronds become brown many are afraid to do anything to them, as they are afraid they might kill the plant, and when they remain the young growths spring up between in summer. They are rendered unsightly by a withered undergrowth, but to allow the old fronds to remain is not the best mode of treating them, and no one can do better early in the season than cut every particle of top off their Maidenhair Ferns, and allow them to break into new growth altogether. They should be kept rather dry at the root some time before the operation, and the old fronds and stems should be cut in as close as possible to the crown. If watered after this and placed in a gentle heat a multitude of young fronds will soon appear. There is no better mode of securing a beautiful Maidenhair Fern than by submitting it without mercy to this treatment, and if every one of them were subjected to the cutting-over process annually none but fresh green plants would be seen anywhere.

Some may be inclined to think that this annual cutting would prevent the plants becoming rapidly large, but it does not, as it is not a quantity of half-decayed fronds which forms a fine plant, but the size and vigour of the crown and roots, and the winter cutting does not disturb either of these. Respecting potting the Maidenhair Ferns, I do not approve of repotting annually, and if the pots are of a fair size and the roots in good condition, repotting should not be attempted oftener than every other year.

Root-bound plants are greatly benefited by copious supplies of liquid manure in summer, and we would rather deal with a plant of this sort than with a small plant in a large pot, and with a large quantity of soil in it not possessed by the roots. We have found the best time to pot is not when cutting over is done, but some weeks afterwards, and when the young fronds are about 2 inches long. If carefully repotted then they will push on freely; but we have found plants repotted at the same time as they were cut over often very shy in starting into growth. The best material we have ever used for potting consisted of rough fibrous loam mixed with a small quantity of horse droppings and silver sand. Perfect drainage is absolutely necessary to their successful culture.—J. MUIR, *Margam*.

#### THE NEW ZEALAND FORGET-ME-NOT.

QUITE a sensation was caused at the meeting of the Royal Horticultural Society on April 13th, when E. G. Loder, Esq., Floore, Weedon, Northamptonshire, exhibited a group of the remarkable New Zealand Forget-me-not, *Myosotidium nobile*. Many of those present were familiar with the plant, and some had tried their skill in inducing it to flower, but very few have been able to record a success in this respect, although it is not difficult of culture so far as keeping the plant in health is concerned. To what this shyness is due it is difficult to determine. The family to which it belongs includes a number of the most floriferous of our hardy plants, and from the vigorous habit of the plant we should expect an equally free-flowering character. It is probably due, however, to some local circumstances in its natural habitat with which we are not familiar, or to some inherent peculiarity of the plant that is not yet understood. Since Mr. Goldsmith has succeeded in flowering the plant so well this season we shall look with interest for another season; and if he is equally successful, then it may be concluded that he has discovered the secret which has puzzled so many.

The system adopted at present is simple in the extreme. The plants are grown in a compost of loam and leaf soil with one-third horse-droppings and a plentiful admixture of sand to render the soil porous, for though water has to be supplied liberally the slightest approach to stagnation about the roots must be carefully avoided. A cold frame is found to be the best situation where ventilation can be given freely in fine weather, but where also adequate protection from frost can be afforded. The plants start into growth quickly in the early spring, and the leaves advance rapidly, the flowers this season having commenced showing at the commencement of April, and at the meeting on the 13th, when exhibited, they were fully expanded on the majority.

cyme. The corollas are about half an inch in diameter, of a brilliant blue colour in the centre shading to white at the margin, and much like the common Forget-me-not in shape. They have a delicacy of beauty that is very attractive, and when once it is found that the plant can be flowered easily and constantly it is certain to become a great favourite.

#### SEASONABLE HINTS ON SOME GREENHOUSE PLANTS.

EARLY April is a very busy time in these structures, as, besides the general cleaning to which the houses and plants should be subjected, there is much potting attention.

*Greenhouse Hardwooded Plants.*—Before potting or interfering with

Fig. 63.—THE NEW ZEALAND FORGET-ME-NOT—*MYOSOTIDIUM NOBILE*.

*Myosotidium nobile* was first introduced to this country through Mr. Watson of St. Albans, and plants were exhibited in flower at one of the London Horticultural Society's meetings in March 1858. The plant is a native of the Chatham Isles, near New Zealand, and is botanically notable as presenting a combination of the characters of several genera in the Borage family, its chief resemblance being to *Myosotis* and *Cynoglossum*; it was, indeed, first assigned to the last-named genus, but was subsequently separated under the name it now bears. The leaves are heart-shaped, 8 to 10 inches in diameter, of a bright shining green colour with deep veins, and they have been compared to the young leaves of Cabbages, to which they possess some resemblance, but the green shade is darker and brighter. The flowers are produced in an inflorescence somewhat like that of the *Myosotis*, and is termed a scorpioid raceme or

the plants for that purpose it is important that the ball be properly moist, for if dry when shifted it is next to impossible to get it thoroughly moistened afterwards; or if that be effected the fresh soil is saturated. The roots of the most delicate hair-like character do not take to it kindly, the soil being sodden and sour before the roots penetrate it, whereas if the fresh soil is not wetted after potting the roots take to it at once, and the plants start into free growth. The peat when used ought not to be dry, but it must be in a medium state of moisture, so that when pressed firmly it will feel clean and elastic in the hand. The plants must be watered overnight, so that the water will have had time to drain away, and in this state the pot will come away clean from the soil, the potsberds being removed with greater facility. If these are very much matted with roots it will be better to leave them than destroy a majority of the best roots in doing so. Only loose inert soil should be removed from the sides and surface, there not being any attempt at loosening the ball. Drain well, and use clean potsherds as well as pots. Ram the soil tightly around the

old ball, and if done properly it will appear as forming part of the ball itself, preventing the too rapid percolation of water with the inner part getting its due share. For all hardwooded plants it is advisable to tear the peat up with the hands, removing all woody matters and assort it, taking out the finer portions or earthy matter by means of a fine sieve, using the best and most fibry parts, to which should be added a sixth of coarse white sand. Plants of this character should be kept rather warmer than usual after potting, sprinkling lightly at closing time on fine afternoons.

*Cytisuses and Coronillas*.—Cut these back to an inch or so from the wood of the previous year, and remove any portions of weak and dead wood, and after laying the plants on their sides syringe with soft-soap solution 3 ozs. to the gallon of tepid water over a vessel to catch the solution, and turn the plants round so as to wet them thoroughly in every part. This will cleanse them of red spider. Keep them rather dry at the roots and in an atmosphere likely to insure a good break, or a moist, warm, genial atmosphere, and when they have made an inch or so of growth repot them. Under favourable conditions they will have made sufficient growth for standing outdoors by the end of June, where they will harden a bushy floriferous growth. *Cytisuses* are very useful for early spring flowering, and are fragrant, being bright and effective plants of easy culture.

*Culecolarias*.—Keep a sharp look out on these for aphides. Once let them get ahead and the plants are ruined, as to free them considerable injury is done the foliage. Upon the first appearance of these pests fumigate lightly in dull weather for two or three nights in succession. A cold frame or pit on a bed of ashes suits them best at this season, damping them lightly over just before closing in the afternoon, which will assist in preserving the foliage fresh, and with the liquid manure that should be given frequently but not too strong it will retain its pleasing green colour which is so effective an accompaniment of the flowers.

*Cinerarias*.—The strains of these are so good that it is seldom worth while to raise them in any other way than from seed. There are, however, some that attain such extraordinary fine proportions in size, colour, &c., that perpetuation is desired, which may be done and good plants obtained by encouraging a free growth of the suckers which emerge from the base of the old plants as soon as they have flowered; but I find these side shoots or suckers start more readily if the plants are turned out and repotted, or plunged in leaf soil at a depth sufficient to partly bury the crown, when the side shoots will form roots quickly, especially if the frame in which they are placed be shaded and the interior kept moist by frequent syringings. By this means the double varieties which are so exceedingly beautiful and useful for general decorative purposes can be propagated.

*Primulas*.—Useful as are the single and semi-double varieties that are raised from seed I consider the doubles extremely serviceable for cutting and general decorative usefulness as to render them of especial value, particularly the old alba plena and rubra plena. Marchioness of Exeter, White Lady, Mrs. A. F. Barron, and Earl of Beaconsfield are most creditable to their raiser, Mr. R. Gilbert. Other fine ones are Emperor, Princess of Wales, Annie Hillier, Miss Eva Fish, Mrs. Eyre Crabbe, and King of Purples. These having really double flowers can only be increased by cuttings, or rather divisions of the old plants, and to succeed with them it is necessary to keep the plants a little dry some time previous to detaching them, that they may become a little hardened and the sap reduced, otherwise they are liable to decay when severed. It is a capital plan to cut each division half through on one side about this time, and as low on the stem as possible, and then cover the surface of the pots with some pounded charcoal. This will arrest the sap, and roots, or a callus at least, will be formed, especially if in a fortnight after making the first incision it be repeated on the opposite side a little higher up the stem, being careful not to detach it, adding more charcoal so as to make it cover the second incision. In about six weeks, or by the early part of June, the parts so acted on will have rooted, and should be detached and potted. If not rooted they should be treated like cuttings, getting as much of the base with each as possible, which should be trimmed and freed of the loose parts, and each cutting then inserted in separate pots in sharp sandy soil and stood in a warm house under a handlight with a piece of wood about an inch high under the corners, duly shaded and kept from flagging by an occasional bedewing overhead, but not heavy enough to run into the hearts of the cuttings, a wet condition of the soil being guarded against until the wounds are healed. In the course of three weeks the cuttings will have roots, when they should be gradually hardened.—G. ABBEY.

#### KEENS' SEEDLING STRAWBERRY.

I CAN fully corroborate Mr. Goodacre's remarks at page 268 of the Journal as to the merits of 5-inch pots over 6-inch for early Strawberries. We invariably use that size, and generally with a fair amount of success. While writing permit me also to mention the merits of the old Keens' Seedling Strawberry for forcing purposes. I do not do so in the sense of writing to depreciate the Vicomtesse Hericart de Thury, of which variety we force a quantity, still I always find that Keens' is preferred at the table to any other early variety. It is necessary to mention one thing about Keens'—viz., that on some soils it has a tendency to run out, so to speak, in the shape of a number of plants becoming fruitless. On our moist limestone soil we find it never does this, remaining as fruitful as Hericart, which, it is well known, is one of the most fruitful Straw-

berries in cultivation. I enclose you a few fruits of Keens'—a fair sample of what we have been picking since the 23rd of February.—H. J. C.

[The Strawberries which we received on April 14th were very fine indeed, and with the true Keens' Seedling flavour.]

#### ROYAL HORTICULTURAL SOCIETY.—APRIL 27TH.

DAFFODILS were again in the ascendant at South Kensington on Tuesday; and the Committee of specialists who have taken these plants under their particular care were busy in correcting their names and selecting the best of the novelties for certificates. Hardy flowers, a few Orchids, Messrs. Veitch & Sons' brilliant *Amaryllises*, Messrs. Paul and Son's beautiful Roses in pots, and Messrs. Cutbush & Sons' greenhouse plants, with some smaller groups constituted the principal of the other exhibits.

FRUIT COMMITTEE.—Present: H. J. Veitch, Esq., in the chair; and Messrs. J. Willard, W. Denning, G. T. Miles, James Smith, G. Norman, G. Buyard, S. Ford, John Burnett, and Philip Crowley.

Samples of the Newland Sack Apple were shown by Mr. W. Crump, Madresfield Court Gardens, Malvern. It is not a new variety, but is little known beyond the Malvern district. Mr. Crump writes as follows concerning it, "The best and largest of our late-keeping varieties, a certain cropper, habit and constitution good, flowering late, colour of the flower deep pink, and exceedingly handsome when in flower." The fruits shown were of medium size, firm, and of good flavour for such a late period in the season; and the Committee expressed a high opinion of the variety. It is thus referred to in the last edition of the "Fruit Manual." "This is a Worcestershire orchard fruit, highly appreciated and extensively grown at Newland, near Malvern, and the surrounding villages. It keeps well, does not bruise in travelling, or if bruised it will not decay. It is a great favourite with Mr. Baron Webster at the fruit farm of Newland Court, who says he wishes all his orchards were Newland Sacks and Blenheim Pippin." A letter of thanks was directed to be sent to Mr. Crump. Messrs. J. Carter & Co., High Holborn, showed a long red Radish of American origin and named Knickerbocker. The roots were very large, but were said to be of good quality, and it was referred to Chiswick for trial.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., in the chair; and Messrs. W. Wilks, J. Douglas, W. Bealby, G. Duffield, H. Herbst, Shirley Hibberd, Richard Dean, Thomas Baines, G. Paul, John Dominy, H. M. Pollett, James O'Brien, H. Ballantine, W. B. Kellock, E. Hill, H. J. Lendy, and Dr. M. T. Masters. Messrs. J. Veitch & Sons, Chelsea, exhibited a collection of new *Amaryllises*, King of the Crimsoms, Duchess of Edinburgh, and Duchess of Albany being certificated; the first named was the richest coloured variety yet obtained and was greatly admired. Others represented were Mrs. Whitbourne, veined with crimson on a white ground, and Eclatante striped and veined with rose and edged with white. Mr. S. Ford, Leonardslee Gardens, Hcrsham, sent branches of *Wellingtonia gigantea* bearing numerous cones (vote of thanks). Messrs. T. Cripps & Son, Tunbridge Wells, were also awarded a vote of thanks for a plant of *Cattleya Lawrenceana* with fourteen fine flowers of rich colour. Messrs. Krelage and Son, Haarlem, sent a collection of seedlings of *Fritillaria Meleagris*, differing slightly in colour, and four were selected for certificates. M. Lindeu, Ghent, sent a plant of a variety of *Cattleya* with large handsome crimson flowers, the lip broad with dark veins. A specimen of a new and very distinct *Dendrobium* named *stratiotes* was also shown; it had narrow twisted greenish petals about 2 inches long, the sepals much shorter, broader, and creamy white, the lip spurred at the base, white veined with rose. A plant of *Alocasia Lindenii* came from the same nursery, the leaves heart-shaped, green, with yellowish veins; and Mr. Gilbert, Florist, Dyke Bourne, Lincoln, showed some very fine and brilliant double scarlet *Anemones*.

Mr. G. Bethell, gardener to the Duke of Marlborough, Blenheim Palace, was awarded a cultural commendation for *Epidendrum leucocentrum* nearly 3 feet in diameter and bearing about sixty flowers, the sepals and petals of which are narrow yellowish, the lip three-lobed, and with the column pure white. Major Lendy had several Orchids, for two of which he gained certificates, and the others were varieties of *Odontoglossums*.

The groups from nurserymen occupied the greater portion of the space in the conservatory. Messrs. W. Cutbush & Sons, Highgate, contributed an attractive group of greenhouse plants in flower, some of the most notable being the *Ericas*, the white *Choysia ternata*, several *Eriostemons*, the graceful *Tetratheca verticillata*, *Polygala Dalmatiana*, a useful free-flowering plant; the interesting and pretty hardwooded plant *Hypocalymna robusta*, with its soft rosy flowers, *Genetylis fuchsoides*, and other plants of a similar kind that are too seldom seen either in gardens or at exhibitions. A silver medal was awarded. Mr. G. Stevens, Putney, sent a large group of *Abutilons*, representing a number of bright and soft-tinted varieties like those which Mr. George has shown in previous years. Some of the best were the following:—*Vesuvius*, scarlet and bright red; *Vivid*, *Compactum*, *Brilliant*, *Excellent*, and *Lustrous*; crimson, *King of Crimsoms*, buff with crimson veins, *Mrs. Stevens*; pale salmon, *Mrs. Garfield*; pink, *Pink Pearl* (vote of thanks); orange, *Golden Queen*; white, *Boule de Neige*; yellow, *Cloth of Gold*; and orange buff, *Miss Terry*. Mr. J. Walker, Thame, Oxon, exhibited five boxes of cut Roses, very fresh and sweet; four dozen blooms of *Maréchal Niel* were extremely good. *Niphetos*, *Duchesse de Caylus*, *Cheshunt Hybrid*, *Lamarque*, *Gloire de Dijon*, and *Souvenir d'un Ami* were other good varieties. Messrs. Paul & Son, Cheshunt, had a choice group of hardy flowers, large specimens of the bright yellow *Doronicum austriacum*, *Megasea cordifolia purpurea*, and *Dielytra eximia* being very showy. Several *Saxifrages*, the bright blue *Gentiana verna*, and the bright scarlet *Anemone fulgens* were also notable. The double white or pale blush *Pigmy Rose*, *Anemoneflora* was included in the group with some pretty *Primulas*, *Fritillarias*, and the white double *Wood Anemone*, *A. nemorosa bracteata fl. pl.* From the same firm came a magnificent group of Roses in pots, standards and dwarfs from 3 to 5 feet high, very healthy, and representing varieties which we have previously noted. They were in all respects excellent plants, and it is quite refreshing to see such Roses at exhibitions. A silver-gilt Banksian medal was awarded for the group.

An exceedingly tasteful group of Ferns was shown by Mr. H. B. May, Edmonton, and they afforded a most agreeable change from the rather too

abundant yellow tints of the Daffodils. The plants were mostly small, but were very healthy, arranged in ornamental pots and earthenware rustic baskets, the chief useful Pterises and Aspleniums being noteworthy—*Adiantum Pacotti*, a very compact and useful Fern; the dark *Pteris internata*, *P. serrulata*, *P. cretica*, the exquisite *Cheilanthes elegans*, and numberless others. The group well merited something more than the bronze medal awarded for it. Mr. T. S. Ware, Tottenham, had a bright and beautiful collection of the most effective hardy plants, *Primula Sieboldi* and its varieties with *P. rosea* predominating. Anemones of the fulgens, apennina, and nemorosa types were attractive. A pan of *A. Robinsoniana*, a very fine variety of nemorosa with large pale lilac flowers, was one of the best plants exhibited, the colour being a very delicate one, but it occasionally comes with more of a blue tinge. An extensive collection of the leading varieties of Daffodils in each section was also shown by Mr. Ware, and a silver-gilt medal was awarded for the two groups. Similar honours were accorded to Messrs. Barr & Son, King Street, Covent Garden, for a charming group of Daffodils in numerous select varieties. Silver medals were also awarded to Mr. J. Walker, Whitton, for a superb collection of Daffodils admirably grown and tastefully arranged; and to Messrs. Collins Bros. & Gabriel, Waterloo Road, for a good group of the same kind of flowers. Mr. R. Dean, Ranelagh Road, Ealing, had a small group of Primroses and Polyanthus representing several very rich and pleasing colours.

#### CERTIFICATED PLANTS.

First-class certificates were awarded for the following:—

*Pteris cretica* H. B. May (H. B. May, Edmonton).—A variety of albineata, very sturdy and compact in growth, the fronds slightly forked at the ends. It will be a useful decorative plant owing to its dwarf habit and hardy constitution.

*Cattleya Mendeli* Lendyana (Major Lendy).—A grand variety with broad bluish petals, a very long lip, white, gold in the throat and intensely rich crimson at the tip.

*Odontoglossum luteo-purpureum leucoglossum* (Sander & Co.).—A beautiful form with large flowers, the sepals and petals rich brown marbled with yellow at the base, the lip broad, brown in the centre and pale yellow, nearly white at the tip, which is slightly fringed.

*Cypripedium Hyeanum* (R. B. White, Esq., and M. Linden, Ghent).—A distinct form, the flowers more curious than beautiful, the lip bright green, the dorsal sepal white with green stripes. M. Linden's plant was said to be a hybrid from *C. Lawrenceanum* and *C. insigne*, but the Committee expressed considerable doubt respecting the reputed origin.

*Amaryllis King of the Crimson* (J. Veitch & Sons).—A flower of medium size, but of wonderful colour, a deep scarlet running to the centre. It is the richest coloured *Amaryllis* yet obtained.

*Amaryllis Duchess of Edinburgh* (J. Veitch & Sons).—Flower round, with broad even petals, white veined with rosy crimson. Very attractive.

*Amaryllis Duchess of Albany* (J. Veitch & Sons).—A finely formed flower, the petals round, broad, and even in size, crimson with a white centre.

*Beaumontia grandiflora* (R. Ruffett, Panshanger).—A handsome shrub, bearing very large trumpet-shaped white flowers, resembling those of the *Brugmansia suaveolens*, but the *Beaumontia* belongs to a different natural order, the Apocynaceae. The leaves are elliptical, 6 to 8 inches long and 3 broad, somewhat like those of *Luculia gratissima*; they are borne in axillary clusters near the points of the growths, the corollas being 6 inches long and 4 inches broad, with five round lobes, pure white and fragrant. It is by no means a novelty, and has been cultivated in stoves for some years, but we believe the plant from which these flowers were sent is trained to the back wall of a conservatory.

*Seedling Fritillarias* (Krelage & Son).—Four varieties were certificated, but they were neither so distinct nor so beautiful as many we have seen. *E. H. Krelage* has a deep red chequering, *Corneille* is purplish, *Van Lerios* greenish, and *Siege of Haarlem* yellowish.

*Oncidium undulatum* (Major Lendy).—A large-flowered species bearing a long straggling raceme, the sepals dark dull green, the petals barred with a similar colour on a white ground, and the lip of a curious pale purplish hue.

*Rose Gloire Lyonnaise* (Paul & Son, Cheshunt).—A Hybrid Perpetual with white blooms, or slightly tinged with sulphur in the centre; the petals shell-like, recurved at the edge, very neat in the bud, but rather loose when partly expanded.

*Polyanthus Jack-in-the-Green Crimson Beauty* (R. Dean, Ealing).—A pretty variety with a large foliaceous calyx and rich crimson corollas.

*Narcissus Nelsoni aurantius* (T. S. Ware).—A charming variety with white perianth divisions, the crown small, very neat, light orange fading to yellow at the base.

*Narcissus Henry Irving* (T. S. Ware).—One of the large-crown forms, of fine shape, the corona of a rich gold tint and yellow perianth divisions.

*Narcissus Leedsi Duchess of Westminster* (Barr & Son).—Perianth divisions white, corona pale clear lemon stained with orange.

*Narcissus Leedsi C. J. Backhouse* (Barr & Son).—Another of the same type as the above, with yellow perianth divisions and a rich orange corona.

#### SCIENTIFIC COMMITTEE.

R. McLachlan, Esq., in the chair; Messrs. W. G. Smith, Michael, Pascoe, Smee, Ridley, O'Brien, G. Murray, G. F. Wilson, Dr. Masters.

*Isosoma*.—Mr. McLachlan, referring to this subject, repeated his doubts as to whether this insect was really the gall-producer on the roots of *Cattleya*, as he had bred a *Cecidomya* from the galls—a much more likely insect to have effected the mischief. Mr. O'Brien, on the contrary, had no doubt that the *Cecidomya* was the cause of the mischief.

*Peziza on Anemones*.—Mr. W. G. Smith exhibited specimens of this fungus attacking the rhizomes of *Anemone nemorosa*. It was suggested that the roots had previously decayed. Mr. Smith also showed the *Puccinia* on *Adoxa moschatellina*; the fungus, it appears, persists during winter on the roots. Mr. Smith had also infected seeds, with the result that the seedling plants were also affected.

*Beetroot*.—Mr. Smee showed a Beetroot which had developed itself under a stone, apparently without leaves. The subject was referred to Mr. Ridley to examine and report.

*Growth on Passiflora*.—Dr. Masters exhibited a specimen with a singular outgrowth, such as is frequently seen in Vines and other plants, but the

cause for which is not known. The specimen was referred to Mr. Michael for examination and report.

*Rhododendron nivum*.—Mr. Bateman exhibited a specimen of this species in flower from his garden at Worthing, where "this and other species appear to succeed perfectly in a north aspect and under cover of some 20 feet of nearly perpendicular rockwork, which affords effectual protection from sea breezes and the rays of the sun." The flowers were relatively small and of a dull lilac colour. The under surface of the leaves is covered with cream-coloured down.

*Australian Acacias*.—Mr. Bateman also sent for exhibition specimens of *Acacia verticillata* in bloom, and which had had no protection other than that afforded by a south wall. Flowers of *A. undulata* and *A. ligustrina* were also shown, which had been grown without fire heat in a glazed porch.

*Portuguese Narcissi*.—Dr. Masters exhibited specimens and drawings of certain Portuguese Narcissi from Prof. Henriques and Mr. Tait of Oporto. They comprised forms of *N. triandrus*, showing great variability in the relative lengths of the stamens and style, and of the form called *N. Henriquesii*, in which the perianth-tube was reduced to a minimum.

*Auricula*.—Dr. Masters showed for the Rev. F. D. Horner a flower of *Auricula* with a dark red ground and a green edge; a form mentioned in his paper read before the Primula Conference. It was recognised as an entirely new departure, and likely to excite great attention among *Auricula* growers.

*Gladiolus*.—Rev. J. T. Boscawen sent specimens of a *Gladiolus*. Referred to Mr. Ridley.

*Tobacco Culture*.—Colonel Clarke sent a communication on the culture of Tobacco in this country, in which he summarised the principal conclusions as follows:—1, Cultivation of ridges. 2, Removal of all laterals. 3, The earliest harvesting of the crop consistently with a proper ripening of the leaf. 4, The absolutely dry state of the leaf before packing for fermentation. Dr. Masters alluded to the culture of the plant in Belgium and Northern France and to the analyses published by Boussingault.

*Marshall P. Wilder*.—It was resolved on the motion of Dr. Masters that a letter of thanks be sent to this gentleman for his contribution to the library, and that the opportunity should be seized to congratulate the venerable President on the continuance of his useful labours in the promotion of all branches of cultural science.

*Orchid Nomenclature*.—In consequence of a communication from the Council it was resolved that a sub-committee be formed to co-operate "with the Society's Provincial Show Committee with a view to the holding of a conference on the nomenclature of Orchids during the Show to be held at Liverpool." The following gentlemen were selected from the Scientific Committee for the above purpose:—Sir J. D. Hooker, Messrs. Ridley, J. O'Brien, and A. H. Smee. It was suggested that Mr. Harry Veitch should be requested to form one of the Committee.

*Miscellaneous*.—Mr. Wilson showed flowers of *Menziesia empetrifolia*, *Epigaea repens*, and *Rhododendron multiflorum*. Flowers of *Beaumontia grandiflora* were shown from Lord Cowper's garden at Panshanger.

#### AURICULAS AT SOUTH KENSINGTON.

IT was certainly much to be deplored that in a year when the whole genus of the Primulas was brought so prominently into notice, that the flower on which the whole Exhibition hung should have been exhibited under such unfavourable conditions, for not for some years has the Show of the National Auricula Society been so small, or, I may add, so mediocre in quality. This will occasion no surprise to anyone who has ever grown an Auricula and noticed the climatic influences that have been at work. A severe winter does not, as far as my experience, try the Auricula, but it is not that which we had to deplore so much, as that at the period when it ought to be starting into good growth and flower—viz., at the end of January, we had, from that on through February and March, a succession of cold dreary weather without any sun, and with a low temperature, and the Auriculas hardly moved. The hopes of growers revived when, early in the present month, the weather changed and the wind blew from the south. Under their influence the appearance of the plants wonderfully changed, and there was a hope that after all they might come in time; but this hope was short-lived, the wind backed again to the N.E., the plants became almost stationary again, and it became evident that only those who could give the plants fire heat could come to the front, and the result fully justified these forebodings. In the larger classes but two competitors appeared, Mr. Douglas and Mr. C. Turner, and they divided the honours between them. Northern growers, who generally so largely contribute to the success of the Show, were almost unrepresented. Mr. Horner, the champion grower, was absent, and so was Mr. B. Simonite. Mr. Brooklebank was represented, Mr. Pohlman was only there as judge, not as an exhibitor, Mr. Bolton had but a few plants, and indeed a comparison of the number of entries with those of last year will show how great was the falling. In the class for fifty Auriculas there were, as I have said, only two exhibits instead of four. The same was the case in the class for twelve. In that for six there were only four, as compared with six or seven last year. In the smaller classes the difference would not be so marked. These larger collections had all been grown under the influence of heat; indeed Mr. Turner told me that his had had fire heat night and day ever since Christmas, and as a result many of the stalks supporting the truss were spindly and required stakes to support them.

So far as to quantity. I fear my verdict (taking it for what it is worth) must be that the quality of those exhibited was by no means equal to that of former years. This must also be attributed to the season. When flowers are long in opening, and when they fail in obtaining the sunlight in which they rejoice, it must be that they suffer from it, and I saw flowers that obtained prizes on Tuesday which would have been simply nowhere in other years. The sorts were the same. There was no lack of "cracks," but they were not in their usual form, and even such flowers as George Lightbody and Lancashire Hero would have been re

garded in a good year as not up to the mark. Perhaps my ideas are considered antiquated and pertaining too much to the "old fogey" character, but after all I may be right.

Taking the two collections exhibited for the class of twelves, there were in Mr. Douglas's lot the following:—Verdure, a seedling of his own, with a very pure green edge, but with somewhat too much body colour, giving it rather a coarse appearance; Prince of Greens, a fine truss, with perhaps a trifle too much colour—what a pity that this lovely green edge has so pale a tube, with a yellow one it would be a great beauty; Colonel Taylor, a little rough; Conservative, a very sweet flower of the Smiling Beauty style; Mahel, a seedling green; Charles J. Perry, large truss and fine; George Lightbody, good; and Smiling Beauty in good form. Amongst Mr. Turner's twelve were Lady Sophia Dumaresque (Lightbody), a white edge rarely seen, rather angular but a very showy flower; George Lightbody; Prince Henry, a seedling, not likely to take a first prize. There were amongst the six in Mr. Douglas's lot Abbé Liszt, a very good green edge, the green particularly bright and clear, its defect being too large an eye; George Lightbody, good; Prince of Greens, rather straggling truss, a defect which this fine flower is sometimes prone to. In Mr. Turner's were George Lightbody, neat and clean; Charles Edward Brown, good, a flower that very often comes near to George Lightbody; Traill's Beauty, in good form. Mr. Llewelyn was third with his seedling Greyfriar, rather rough and too much body colour; Acme, good decided white edge; Alderman Wisby, somewhat large.

The class for fifties was of the usual character, some very good flowers and some very indifferent ones. In Mr. Douglas's collection were Dr. Kidd, a seedling; Sapphire, very bright, but I failed to distinguish much difference between it and Charles J. Perry. Frank Simonite would be a fine flower were it not for its pale washy tube; it seems almost impassible. Conservative good, Lancashire Hero in its green character, Prince of Greens good, and Garibaldi (Pohlman's) good dark self. In Mr. Turner's collection there was a good truss of John Warliston, which he does better than I have seen it elsewhere. Confidence, too, large and rough, and Traill's Beauty, good—this flower is very uncertain, sometimes meriting its name, at other times more like the Beast than the Beauty. A very good bloom of John Simonite, a good white edge, was shown by Mr. Potts in the "single" class. Geo. Lightbody took first in greens, but I, as an old florist, should not have called it a green edge, as there was a considerable quantity of the "powder;" daisies, I think Mr. Horner calls it, like Daisies in a green lawn, and it was nearer a grey than a green. Acme came in well in the white edges, and is perhaps the most decided white edge we have. There was a very good plant of Traill's Beauty which took the fifth prize. Amongst these there was a good plant of Black Ben, exhibited by Mr. Bolton, one of Mr. Woodhead's seedlings.

In seedlings there was but little competition, and few prizes were awarded. This is as it should be when the varieties exhibited are not superior or equal to those already grown; for although a prize does not quite give the same position as a certificate, yet it gives a certain value to a flower, and if it is not meritorious may afterwards cause disappointment. Amongst the green edges there was nothing worthy of note. Amongst greys, Mr. Llewelyn had a second prize for a grey edge of medium quality. In whites, Mr. Douglas had a good white edge Snowdon Knight, apparently of the same strain as his Conservative and Sylvia, a good white edge with dark body colour, paste solid and good, and a good yellow tube. There were two good selfs exhibited by Mr. W. Bolton; one, Mrs. W. H. Bolton, a very deep maroon, nearly black, and with a good paste and eye; the other, Mrs. Wilson, a large-sized pip of deep purple. The premier prize in the Show was, as usual, awarded to George Lightbody, a fine truss already alluded to in Mr. Douglas's collection of twelve. It shows how difficult it is, with all the efforts of raisers, to gain anything which surpasses that grand flower. Let us hope that another season may be more favourable. Evidently the growers of the flowers are increasing in number, and we hope that they may have a better opportunity of competing.—D., Deal.

## THE DAFFODIL.

[A paper by the Rev. C. Wolley Dod, read at the Horticultural Club, April 14th.]

(Continued from page 313.)

I NEXT speak of the characters and geographical distribution of several of the wild forms, and I may first remark that our knowledge of wild forms of *Pseudo-Narcissus* is increasing rapidly, and that every year new varieties are being added to our list, or the true home of some old garden variety is being discovered. *N. Pseudo-Narcissus*, as a species, is confined to Europe, and extends from the Atlantic on the west, and the latitude possibly of Edinburgh northwards, to about the longitude of Berlin eastwards. It has been reported as native in Hungary and other parts of the Austrian empire as far east as Transylvania, but Herr Willkomon, Prof. of Botany in the University of Prague, has told me that he does not believe it to be indigenous in those parts. It is unknown in Turkey or Greece. Its head quarters may be considered to be the region of the Pyrenees, and it is most abundant in Southern France, Northern Spain and Portugal, and Northern Italy. Whether it extends quite to the south of these latter countries is uncertain. It is convenient to adopt, as Mr. Baker has done, the five species of Linnaeus as sub-species or sections under which to classify the known wild varieties. These sections are—1, *Pseudo-Narcissus*; 2, major; 3, minor; 4, bicolor; 5, *moschatus*.

I say I adopt these divisions of names for convenience, but I cannot say that they are satisfactory, though I have no better to offer. As the number of wild varieties found grows upon us, we find it more and more difficult to adjust them according to these sub-species. All arbitrary defini-

tions break down. Whether we take colour, or size, or structure, we find from end to end, from the most concolorous to the most bicolorous, from the smallest to the largest, an unbroken series of links, and if we try to make a set of characters to fit particular names, they utterly fail when applied in practice. The minors, the majors, the *Pseudo-Narcissus*, the bicolors of Portugal, of the Pyrenees, of the Maritime Alps, all differ, and have some characters of one name, and some of another, and I therefore adopt these names, with this proviso, and as having, not only no real limitation as sub-species, but no consistent characters reaching beyond the individual variety we may accept as their type.

As for the first, the Daffodil found wild in England has generally been adopted as the type of the species, and of this section. In Devonshire where it is most abundant, it varies most in size, in substance of flower, in deepness of colour of the corona, and in width and recurving of its mouth. The corona, however, is seldom much recurved in English varieties. A form now known as *scoticus* is found in Ayrshire, taller and stouter, and with larger flowers than the type, and earlier in flower, and in its recurved corona presenting a beautiful example of crenation. It is improbable that it is indigenous to Scotland.

I must next mention that I know three places in England, one being in Oxfordshire and two in Dorsetshire, where typical *Pseudo-Narcissus* grow mixed up with concolorous forms, both white and yellow, presenting similar characters to the type. With them grow others resembling the bicolor section. After cultivating these forms and examining them, I believe that they are due to different varieties of foreign origin, planted together by design or accident, the offspring of which are hybrid. The largest development of the section *pseudo-Narcissus* is found in Italy where varieties called *Telamonius* and *princeps* are found in the valleys and lower slopes of the Apennines, the former having the most twisted leaf of any Daffodil I know, and the latter the longest corona, sometimes exceeding 2 inches in length, or more than two and a half times the length of the tube. From the Pyrenees themselves, amongst thousands of Daffodils, I have never received any of exactly the English type, though it may exist there, but the prevailing *Pseudo-Narcissus* of the lower slopes of the Pyrenees, extending west almost to the sea level near Biarritz, is an elegant very pale early Daffodil, which we have imported under two names, *pallidus præcox*, and *variiformis*, the latter name very suitable, as it is a very variable Daffodil both in shades of colour, form of corona, and relative proportions of the parts of the flower. It carries its flowers at nearly every angle to the horizon, and the leaves are distinct in appearance, being hardly at all glaucous. It seems to have been unknown to Haworth, who, in his twenty-nine species of Trumpet or Ajax Daffodil, does not even enumerate any into which it could possibly be made to fit. This Daffodil has scarcely any character which is not inconstant and variable.

The forms included under the second section, major, are mostly concolorous, and of rich yellow. They have often been distinguished as Spanish, but at least one, the *spurius* of modern gardens, is probably native in Italy, and not yet known to be wild in Spain. The Tenhy Daffodil, quite naturalised in South Wales, but of which the true habitat is unknown, belongs to this section. So does that very fine Daffodil, the *maximus* of gardens, which will probably be found native somewhere either in North Italy or Spain, when the countries have been more closely searched in early spring. The nearest wild approach to this form I have yet seen was exhibited by Mr. Ware last year to the Daffodil Committee. He had received it as collected wild near Saragossa, after which town it has been named. Two or three forms belonging, I believe, to this section were sent to me last summer by Mr. Alfred Tait, who collected them wild near Oporto. They are tall elegant flowers, with slender and much-twisted perianth divisions, not imbricated, and I think are new to cultivation. They may develop more when I have grown them longer. These double readily when planted in Mr. Tait's garden, and the double form is an ugly monster. Major is rather ill defined as a section.

Of the third section, minor, the assumed type, as recognised, I believe, by the *Narcissus* Committee has only just now been identified in its wild state; but its exact counterpart in all characters except size, *N. minimus*, is abundant on mountains in the north of Spain. The variety most common in gardens, now called *nanus*, though I shall presently give reasons for thinking that the name is wrong, abounds near Bayonne, where the French botanists call it minor; but the recognised minor, with large lobes, and generally with free divisions of perianth, was found in the Maritime Alps recently by Mr. Scrase Dickens near Gasse. Concolorous and bicolorous forms of it grow there not in separate clumps, but mixed up together in the same clumps, and I have had this season two or three boxes of flowers of it sent to study.

Of the bicolor section the characters are—The leaves thick in substance, very broad and large, not acute or tapering, but rounded off suddenly at the ends; it is late-flowering, the corona is cylindrical or ventricose, slightly lobed, and the perianth divisions often large and loose. Two distinct wild forms are well known—1, *Lorifolius*, which is found in the Pyrenees in North Portugal, and probably in the Apennines; and 2, *N. muticus* of the French botanist Gay, a very distinct Daffodil, covering hundreds of acres on the French side of the Pyrenees near Gavarnie, and in other parts. It is so distinct in its character that Haworth, though he had never seen living plants, assigned to it a separate genus called *Pileus*, and divided it into five species. This is the bicolor of some French local botanists, and we do not know yet any wild form which comes nearer the bicolor of gardens, though we may expect to find some. As regards *muticus*, which is sometimes called *abscissus* in English catalogues, the large broad leaves with rounded ends, the straight cylindrical corona, its late flowering, and other characters claim for it a place

in this section. It seems strange that so distinct a Daffodil has never been figured in any English work.

The last section, *Moschatus*, or the White Daffodil, is very interesting. The only form of it we yet know for certain in its own home was rediscovered about six years ago by Mr. E. N. Buxton on the Spanish slope of the Pyrenees whilst chamois hunting, about 6000 feet above the sea level, near Mount Perdu. It was in May, and at that elevation the flowers were just out. Mr. Buxton at once laid down his rifle, and supplied himself with roots of this new prize, which were the first wild ones brought to England in recent times. Since then this habitat has become known to French collectors, and many thousands of bulbs have been imported thence to England. It has always been supposed that other and larger forms of this section are to be found wild in Spain, but we do not know for certain that any have yet been found, and we want trustworthy information on this point. A character of this section is that the separation of the perianth divisions is marked by a conspicuous line continued nearly to the bottom of the tube. This completes my short notice of the principal known wild forms, but the list of known wild forms will constantly increase, and is growing from year to year. A very distinct variety was sent to me by Mr. Alfred Tait from Portugal early in last month, but not in sufficiently good condition to describe its character. Another remarkable form of Daffodil was sent by the same gentleman with perianth divisions reflexed so as to meet in a point, and with no tube. It is thought to be identical with the *N. cyclamineus* adopted by Haworth from old authors who figured it. If not a hybrid, it seems to demand a species to itself, for it can hardly find a place amongst *N. Pseudo-Narcissus*.

I have followed Mr. Baker in adopting Haworth's names, though I feel all the while that several of them are misapplied. It seems inconsistent to adopt an author's names when the characters given by that author to the plants he describes under those names are manifestly at variance with the characters of the plants to which we apply them. For instance, Haworth's *N. minor* was a flower with imbricated perianth divisions, whilst we now apply it to a flower of which a distinctive mark is its free perianth divisions, and the same inconsistency applies to *N. minimus*. Again, the *N. nanus* of Haworth was a pale sulphur-coloured Daffodil with leaves half an inch wide. Our *N. nanus* is a full yellow, with leaves narrower than those of *minor*. I am at a loss to know what variety Haworth intended by the name *rugilobus*, which he classes under the section *Pseudo-Narcissus*; but it is now transferred to one belonging evidently to the bicolor section, and identical, so far as I can judge, with *lorifolius*. The same uncertainty attends several others of the names of Haworth in their recent application.

We now pass on to speak of *N. Pseudo-Narcissus* as a cultivated plant, and of the changes and improvements which have taken place or may be expected to take place in its development under cultivation. Some of the finest forms, as *Emperor*, *Empress*, *Horsfieldi*, are believed to be varieties of cultivation, because they are not known to have been found wild, and the names of the growers are known; but whether they were produced by artificial crossing or by careful selection of seed from the finest flowers, and from seedlings raised under the most favourable conditions, we have not certain information, though the latter supposition is more probable. In a species in which so many and distinct natural varieties exist it seems not unreasonable to expect that there would be a strong natural tendency in the seed to produce varieties, but there is not sufficient evidence to support this belief. On the other hand, the more we become acquainted with large beds of wild Daffodils growing away from the influence of other varieties, the more we are led to the conclusion that like produces like in Daffodils as in other plants. We find, for instance, that the Daffodils of the north of Portugal form a set of varieties distinct from those of the Pyrenees, whilst the Maritime Alps and North Italy have special forms which retain their distinct characters. We must not dogmatise on these matters, but let us consider the case of the Tenby Daffodil, which ripens seed and grows from it more freely than any variety I know. It covers several acres in South Wales, where it has grown for many generations; yet it continues remarkably constant to form, and varieties are hardly ever observed. Many similar instances might be mentioned. In gardens, on the other hand, where many varieties are in flower together, when we consider the readiness with which some distinct species of *Narcissus* produce hybrids, we may infer that *Pseudo-Narcissus* will readily cross with varieties of the same species, and we reasonably expect spontaneous varieties from seed.

Few of us have patience to raise successive generations of Daffodil from seed, keeping them carefully labelled for all the years—probably six at least—until they flower. So the history of new varieties raised in gardens is seldom known. It is more easy, however, to notice and record changes where no raising from seed takes place, changes which are produced by continued cultivation under favourable conditions of soil and climate. These conditions seem particularly favourable in many parts of Ireland, and I will give examples in illustration. I am indebted to Mr. Barr for calling my attention to the remarkable development in size and vigour which takes place in the Botanic Gardens at Dublin in the case of the variety of Daffodil called *maximus*. The size of this variety in those gardens is such that Mr. Barr for long believed it to be a distinct and gigantic and early-flowering variety. When, however, it is planted in England side by side with *Maximus* from Holland, and under the same conditions, the contrast the first year is very conspicuous. After a few years the two gradually assimilate themselves, until no difference can be seen. Another variety common in Irish gardens, and to some extent naturalised in Ireland, is named *Princeps*. As grown in Ireland this is

perhaps the largest of all Daffodils. It comes to us from there in several sizes, as *Princeps maximus*, *Princeps minor*, and so on. I can hardly say whether these differences are maintained in any gardens in England, but I can assert that after two or three years all the varieties of *Princeps* become so degenerate in Cheshire as to produce flowers hardly larger than those of the wild type of *Pseudo-Narcissus*. I may mention, too, the fine Daffodil called *spurius*, which has, I believe, recently been found wild by Mr. Engleheart in Italy. *Spurius* is a very old variety in the Dutch bulb farms, and comes thence to England bearing flowers of one size. It is now known that this variety is common in Ireland both as a naturalised and as a garden plant, and in more than one size, some resembling the Dutch plant in every particular except size, but being much larger. This may be due to the favourable conditions in Ireland for its growth. I have cultivated the large form for six years, and it still maintains its majority; but whether it will in time reduce its dimensions to the Dutch size time will show.

I will further add that it is useless to compare the merits of or to attempt to identify Daffodils until they have been grown together under the same conditions for a year or two. When this has been done we want continuous observations and careful notes of them through a series of years to see what changes soil and climate make in the same variety, in colour, size, habit, and form, especially noting the recurving of the corona to see whether this character is quite constant or due to climate or soil in any degree.

Again, we cannot be sure until we have tried them for at least two years what varieties are best suited to the special conditions of our own gardens. Daffodils, according to their variety, have their likes and dislikes. Most of them prefer rich rather sandy loam, retentive, but well drained, and on the cold stiff subsoil of my garden in Cheshire nearly all do better on raised beds. The *moschatus* section alone seem to like lighter soil of a peaty character. *N. minor* and *N. minimus* seem rather delicate and dislike wet; their flowers, which are dangerously near the ground, are much relished by slugs, and require, where such vermin abound, to be protected by perforated zinc collars or by a dressing of powdered tobacco—a valuable preventive. Several Daffodils are, comparatively speaking, failures in my garden. I have already mentioned *Princeps*. The major of trade produces few flowers and the foliage looks unhealthy. *Maximus* increases slowly, and is liable to be attacked by an obscure disease, which rots the base of the ball and prevents the formation of fresh roots. The Italian *Telamonius* looks healthy, but does not flower freely. The most floriferous of the larger kinds in my garden is *spurius*, whilst *Pseudo-Narcissus*, the type, said to degenerate and die out in some gardens, flowers and flourishes extremely well. So do *Horsfieldi* and *Emperor*. I have mentioned these instances to show that Daffodils require to be proved in each garden and selected accordingly.

#### AT WHAT DEPTH OUGHT DAFFODILS IN GARDENS TO BE PLANTED?

The answer depends partly on the variety to be planted, partly on the character of the soil and the subsoil; but let everyone who can make patient experiments and carefully record his observations on this point. My own experience is generally in favour of deep planting, especially in raised beds where the drainage is good. Such Daffodils as these called *minor* and *nanus* should, of course, not be planted more than half as deep as *Horsfieldi* and *Emperor*. In deep well-drained soils I plant from 4 to 6 inches deep in the case of the smallest kinds to a foot in the largest. When Daffodils that have been dug up wild are sent to us in leaf it is easy to see at what depth they have grown; and not only have I taken notice of this, but have inquired of those who have dug up Daffodils much abroad in their native homes. These accounts agree in telling of huge Daffodils with flowers as large as *Emperor*, which, after long and laborious digging, the finder was obliged to relinquish because they grew so deep. Some very fine Daffodils just received from Italy, where they grow wild, reported to resemble *maximus* in appearance, have grown at a depth varying from 12 to 18 inches; and my friend Mr. Engleheart mentioned others still larger, none of which he succeeded in digging up. Mr. Tait sent me the leaf and flower of a *lorifolius* found near Oporto, being as large as those of *Emperor*, the bulb of which was deep beyond his reach.

On the other hand, a number of *minor* sent last week from the South of France had grown at an average depth of 3 inches. The soil was rocky, and a large proportion of Oak-leaf mould was mixed with it on the surface. We must not, therefore, try to make our rules for depth too absolute. I need not point out that deep planting enables the gardener to cultivate other plants over them in summer, which may be done without any damage to the bulb, provided that the growth of the leaves is not interfered with, and the soil sufficiently enriched by a top-dressing.

Daffodils do far better on a border facing, in autumn, a south than with a north aspect. The doubling of Daffodils is a subject to which I have long paid special attention, though on several points connected with it my mind is by no means made up. It is certain that *N. Pseudo-Narcissus* doubles into a variety of forms, two of which may be particularly noticed. (1) The form in which the corona remains entire, and the doubling is confined to the inside of it; this we call the semi-double form. (2) The form in which the corona is split into six segments and spread open. This we call, for distinction, *Rose-double*. I have quite satisfied myself, by long observation, that these forms are not constant, but are often interchanged from year to year, depending upon conditions of soil and cultivation. About this time last year nearly 100 double typical *Pseudo-Narcissus* were sent to me, which were dug up wild when in flower. All of these were semi-double; but this year nearly all which have flowered at all have become *Rose-double*. In the southern counties of England and Wales the type *Pseudo-Narcissus* is often found double, growing mixed up

with single forms. It is hardly ever the Rose-double, but when transferred to gardens the Rose-double is the commoner form for it to assume. In spite of their taking that form, their tendency, in my garden, is to become constantly less double, until the divided corona closes together again, and the flower becomes entirely single and perfect in all its organs. These same bulbs, if sent to their native soil, produce double flowers again in a year. On the other hand, I have never, by any soil or cultivation, succeeded in persuading any single Daffodil to double in my garden. As regards the frequent assertions made that in some gardens the typical single wild Pseudo-Narcissus will change in a few years into the large double Daffodil called *Telamonius*, these assertions are too consistent, and made, I am certain, in too good faith to be at once rejected; but they require very careful investigation, which I have long been making, and still continuing to make. Botanists assure me that no metamorphosis of any part or organ is necessary to effect this change. That single Daffodils in some soils and under some conditions will produce double flowers is nearly certain. Mr. Tait of Oporto sent me last summer a bag of double-flowered Daffodils, which he assured me were dug up in the neighbourhood single, and when planted in his garden became double. There is no mistake about identity of variety in these; the single kind is unlike anything I have ever before seen in cultivation in England, and the double flower, although a hideous monstrosity, evidently belongs to the same variety; but, as I said before, assertions of this kind require careful sifting.

To conclude, lovers of the Daffodil may be congratulated on having a favourite which is easy of cultivation, presents endless variety, and gives less cause for anxiety through accidents than most flowers. Few destroyers, whether mice, or birds, or wireworms, attack the bulb of Daffodil. The Narcissus fly is a pest of a warmer climate than ours. Dwarf forms like *N. minor* and *N. minimus*, as I said before, invite slugs, which, however, attack the flower only. High winds, too, are serious enemies to Daffodil flowers. A westerly gale on March 31st snapped off at the ground line some of my best opening flowers; so that Daffodils should either be planted in a sheltered place, or, if in windy quarters, be tied up; but upon the whole there is no class of flowers which give a more satisfactory result with a less amount of labour than *N. Pseudo-Narcissus*.

### CULTURE OF DIPLADENIAS.

WHETHER grown into large trained specimens for exhibition or for the decoration of the stove, these lovely climbers must always hold a foremost position amongst our choicest stove plants. If not wanted for exhibition the best plan is to fasten a trellis of wires underneath the roof of the house and at 8 or 10 inches from it. Over this the plants should be allowed to ramble freely, taking care to keep the shoots evenly and thickly disposed, so as to allow plenty of room for the proper development of the leaves and perfect ripening of the wood, which is highly essential to the free production of their flowers. Grown in this way, with some of the dark highly coloured flowers produced by *Brearleyana* and *hybrida* side by side, or intermingled with the delicate rosy pink ones of *D. amœna*, they present one of the most charming sights imaginable. The flowers when gathered are very attractive arranged in shallow dishes with a few fronds of *Adiantum gracillimum* forming a sort of screen over them, and if gathered in the morning when the house is coolest they remain in good condition for several days.

Dipladenias are easily propagated by means of cuttings. These will root at any time of the year, but the best time is in the spring, and the cuttings to be preferred are the young growths from the preceding year's wood, taken off with a heel when about 3 inches long. Inserted singly in 2½-inch pots, in a mixture of half peat and half sand, and placed under a bellglass in the hottest part of the stove, these will form roots in about a fortnight, and must then be gradually exposed to the ordinary temperature of the house. Next to these I prefer cuttings made from strong half-ripened shoots, such as may be obtained in May or June, but by striking them in the early part of the year they get fairly started before the hottest weather comes, and perfect their growth before winter.

To grow them well—and if not well grown they are best left alone—they require a rather high temperature when in active growth, and even in winter when at rest they must never be subjected to a lower temperature than 50° to 55°. If wanted to flower in May they must be started early in January, but generally speaking the beginning or middle of February is soon enough. At first starting they should be given a temperature of 60° to 65° at night, with a rise of 5° by day, gradually increasing it as the days lengthen, until by the end of April it ranges from 70° to 75° at night, and from 75° to 80° by day, allowing it to rise to 85° or even to 90° with sun. They delight in a moist atmosphere, and must at all times be shaded from bright sunshine, admitting at the same time as much light as possible. For this purpose the house should be provided with blinds, so that they may be rolled up and the plants exposed to the full influence of the light on every occasion when there is no sun.

The soil for Dipladenias should consist of three parts brown fibrous peat to two parts loam, which must be as turfy as possible, and all fine soil removed from it by sifting; to this add one-quarter part each of sand and charcoal, the latter broken to the size of acorns. A small quantity of Standen's manure may be added. If really good turfy loam is not available they may be potted in all peat; on no account should poor loam, destitute of fibre, be used. The pots must be well drained, and great care exercised in watering at all seasons, few plants being more liable to injury through neglect in this respect than Dipladenias. During winter especially, and before they have fairly taken to the new soil after potting, water must be cautiously applied, allowing the soil to get thoroughly dry before watering, but not to such an extent as to cause them to flag. I have seen them

treated as deciduous plants, and made to lose all their foliage in winter by keeping them dry at the root, but such treatment is decidedly wrong; they are naturally evergreen, and must at all times be given enough water to enable them to retain some of their leaves fresh and healthy.

Almost all kinds of insects to which stove plants are subject will live on Dipladenias, but with proper treatment the only ones whose attacks need be feared are mealy bug and brown scale, and these—provided the plants are thoroughly cleansed before they are started in spring—can generally be kept pretty well in check by using the syringe freely mornings and afternoons. Should they become too firmly established to be kept under by these means, syringing with that best of all insecticides, petroleum, will get rid of most of them. A wineglassful of petroleum to three gallons of water is as much as it is consistent with safety to use, as when growing freely the young leaves are very tender and easily injured. Even this quantity must be carefully applied, mixing it well with the water before syringing it over the plants, and washing it off with clean water a few minutes after. Keep them well shaded for two or three days, and, if properly managed, no evil will result from the application, which, if necessary, may be repeated in a week or ten days. Scale may be got rid of in the same way, but, being more difficult to destroy, it is generally necessary to syringe the plants three or four times in succession at intervals of not less than a week.

As soon as the flower buds appear give weak manure water at every alternate watering; that made from fresh cow or sheep manure and diluted with clean water to the requisite strength is as good as any for them. This will greatly prolong their season of blooming, besides making the individual flowers much finer in every respect. Without some such aid the trusses produced after the first flowers open will be very weak and will have only a small quantity of buds on each; strong trusses will frequently produce as many as thirty flowers in succession, lasting over a period of nearly two months.

Any plants that are intended for exhibition should be supplied with balloon or other shaped trellises of the size they are likely to require, and the whole of the wood fastened thereto before they are started. Each young shoot when about 3 inches in length should have a string placed for it to climb on, running from the trellis to the highest part of the roof, always, as before mentioned, giving each shoot a fair amount of room.

Comparatively small pots should be used, those 14 or 15 inches in diameter being sufficiently large for even the finest specimens. In pots of this size they may be grown year after year, turning them out just as they start into growth, and removing enough of the old soil to permit their being placed in the same pots again.

There are some varieties of Dipladenias with which I am unacquainted, but the following are all good, thoroughly reliable, and sufficient for almost all purposes—*amœna*, *hybrida*, *amabilis*, *crassinode*, *splendens*, and *Brearleyana*. The last named, with its flowers opening a delicate rosy pink colour, and changing with age to the richest crimson, is decidedly the finest of this truly magnificent genus of stove climbers.—C. L. P.

### GARDENERS AND PREMIUMS.

IN a recent number of the Journal your correspondent, "Thinker," made some allusions to the decline of the above. Hundreds of young men have paid premiums, and in return have received no more recognition from the head gardener than if they were day labourers, though the money is presumably paid for special instructions, &c. It is in the power of an intelligent chief to impart £5 or £10's worth of good to a youth in the course of two or three years, as I can testify from experience. My object at present, however, is not to defend or condemn the system, but to record what appears to me to be a very hard case and representative of many others from the same establishment. A young man has just left the gardens of an earl, where he had been engaged to perform certain duties with the understanding that he would be expected to pay a premium of £5 in an indefinite time. Before he had been in his place a month he was asked how he intended to pay this sum, and he replied by two or three instalments; but to his astonishment the following pay day 2s. was deducted from his wage, then after a time 3s.; and when he asked for an explanation he was as good as told that "if he did not like it he could go." Shortly he was set to perform duties the reverse of those he had been engaged for, and other matters were made disagreeable to him, obviously with the view of forcing him to give up his place in order that the "teacher" might extract the best part of £5 from another young man, and so make the premiums average that sum per man per annum, which in the case of seven or eight men would be a nice little sum. You will see, Mr. Editor, that if the matter was left to the men they would most likely pay a portion the end of the first year and the remainder the second; and some might enter the third before completing payment, which would evidently reduce the ill-got gains by one-half. It was understood on the place that his lordship some time ago made an allowance to the gardener of 1s. per week per man in order to abolish the premiums. This, if true, is a serious indictment, and it is a question whether the young man's friends will not inquire from his lordship whether the gardener had a right to do as he did. What says "Thinker?"—W. P. R.

### NEW CONSERVATORY, THE MANOR HOUSE, THAMES DITTON.

WE are this week enabled to present our readers with a view of the new conservatory recently erected by Messrs. J. Weeks & Co. of Chelsea, in the garden of the Manor House, Thames Ditton, for Hanibal Speer, Esq.

The conservatory is built in what is known as the Queen Anne style of architecture, so as to harmonise with the mansion, which is a very fine example of that style. It will be seen that the building is span-roofed, oblong in shape, with a large recess on the east side, surmounted with a gable; but the chief and novel feature of the arrangement is the picturesque and somewhat unique treatment of the front, which is formed

white transparent glass in the ordinary way; the small upper squares are filled in with pale neutral green glass; the transom sashes are glazed with tinted lead glazing, and the roof with one-eighth rolled plate. The details have all been carefully considered, all the parts are admirably proportioned, and the general external effect of the building is most satisfactory.

Fig. 64.—NEW CONSERVATORY, THE MANOR HOUSE, THAMES DITTON.

into a large and highly ornamental open projecting porch, the roof of which is carried on square and octagonal columns with carved cups and bases, and which is provided with seats facing the lawn. This porch forms a most agreeable lounge, from whence the sports or games being enacted on the lawn may be witnessed. The glazing of the building is varied and effective. The lower squares of the sashes are glazed with

No less care and judgment have been displayed in the arrangement of the interior. The building has not been cut up into a number of small beds and paths in the usual manner, but the centre has been left free for promenade, leaving a clear view from end to end. Exactly opposite the door at the opposite end of the building is a small group of rockwork covered with Ferns and having water trickling down into a small pond,

and round the sides are artistically shaped beds formed of stone cable edging, bordered with flowers and backed up with large and choice plants and trees, the whole forming a striking and effective comp d'oeil. The floors of both conservatory and porch are covered with black and white encaustic tiles in very small squares of Messrs. Minton's manufacture, and every portion of the building is of first-class design and workmanship.

The general effect is further enhanced by the tasteful arrangement of the surrounding grounds, which, amongst other numerous attractions, contain some very choice Cedars.

#### KITCHEN GARDEN.

OUR principal enemy this spring, the ungenial weather, appears to have departed finally, and the soil has been in capital order for sowing and planting. Early crops are growing rapidly, and our kitchen garden has now quite a spring-like appearance. Those who are behind with their cropping should push the work forward as fast as possible.

**POTATOES.**—The whole of the early ones should have been planted some little time ago. Those along the bottom of our Peach wall are now 6 inches high, and as they have enjoyed the protection afforded to the trees while in bloom they are healthy and strong. Those planted in rows across a south border are about 2 inches high, and as soon as they become this height they should be earthed up. This affords the stems support and shelter, and must be always practised. Where manure was deficient at planting time sprinkle a little guano or some artificial manure round the plants before earthing up. Planting late Potatoes must be finished as soon as possible. The Champion, Magnum Bonum, and some others make more stem than the early sorts, and they must be given more room. From 2 feet to 30 inches is not too much from row to row for late Potatoes, and the sets should be placed 18 inches apart. Frame Potatoes now being dug are turning out well.

**ASPARAGUS.**—This is very late this season. Some seasons we have cut quantities from the open during the first and second week in April. This year we shall not be able to cut in any quantity until the first week in May. Our main piece for cutting is 30 yards wide and 100 yards in length, the whole of the roots being planted from 2 feet to 3 feet apart, and the first wet day a handful of guano will be sprinkled round the plants to assist in strengthening the young growths that will be cut during the next month, also to benefit those which will be left to grow throughout the summer.

New plantations may now be made. Those who buy roots should procure them two years old at least, and three years if they wish to make a good beginning and cut largely next year. We always raise our own seedlings; but some may not have the convenience to do this, and others who have not sown seed last year or before that to produce roots may not be inclined to wait until seed sown now would produce plants. Before any attempt is made at planting, the ground must be thoroughly prepared for the roots. It must be deeply dug and heavily manured, and where the soil is heavy a quantity of sand or light road scrapings should be added, as the roots being very fleshy are apt to perish in stiff soil. The roots may either be put in beds or planted on the level without forming these; in any case they should not be planted closer to each other than 18 inches each way. Spread the roots out star form without being cramped or twisted round, and the holes should not be more than 6 inches in depth. In buying roots from a distant nursery the holes should be ready on their arrival; they should be forwarded by passenger train, and the shorter the time they are out of the ground the better, as it is very injurious to allow them to become dried. If the weather is dry at the time of planting water immediately afterwards.

Asparagus seed should also be sown; 1 oz. will produce some hundreds of roots. It ought to be sown in light rich soil in rows 18 inches apart and 2 inches deep. As the young plants will remain in the seed rows for one year at least, sow thinly, and where ground is scarce rather keep the rows 9 inches or 1 foot apart than sow thickly to get a certain number of plants.

**BEEF.**—Half the main crop of the long sorts, such as Dell's Crimson, should be sown now, and the other half in a month or so, as moderate-sized roots are more desirable than very large ones. Soil medium in richness and rather open will produce fine clean roots. Sow in drills 15 inches or 18 inches apart, and 2 inches deep, and remember it is only a waste of good seed to sow thickly.

**PEAS.**—If the weather becomes very dry give the earliest rows a good watering with liquid manure. Stake all advancing crops before they fall to one side. Sow quantities of main crop varieties for use about the end of July and the beginning of August, the trench system only being practised at this season.

**BROAD BEANS.**—Early crops are pushing on rapidly, and if any are wanted in July sow at once. Those intended for exhibition should be sown in trenches with a large quantity of strong manure forked in before sowing the seed. Carter's Leviathan is supreme for showing.

**KIDNEY BEANS.**—These include Dwarf and Runner varieties. They are sometimes sown in the open before this time, but success rarely follows early sowing, as the seed is tender and apt to perish in the cold soil, while the young plants are more tender still, and if not checked by frost they often assume a yellow hue, which makes them very unprofitable. The first week in May, however, is not too early to sow generally, and by giving them a warm sheltered spot they will grow freely and produce profusely almost as early as any sown weeks ago. A few rows of Ne Plus Ultra, Osborn's, or some other very early sort may be sown as well as a small quantity of Canadian Wonder to succeed these. Keep the rows about 20 inches apart, and do not sow the seed deeper than 2 inches. Cover up if possible with a quantity of light old soil from the potting-shed, as in wet districts or cold soils this helps the germination of the seed and free growth of the young plants. A row of Runner Beans may be sown at the same time. Make a shallow trench, dig plenty of manure into it, sow the seed 3 inches from the surface, cover with the soil above recommended, and a fine crop of early Runners will be the result.

**SPINACH AND TURNIPS.**—The early crops of these grow but slowly. We never had spring Turnips so backward, but successional crops must be put in, and a good sowing of both of the above should be made. To have the leaves of summer Spinach large and succulent the seed must be sown in rich soil; in poor material it would be a failure. Before sowing the Turnips sprinkle a quantity of soot or lime over the ground. Dutch hoe it in, then open the drills, and sow the seed, and the fly or grub will not be troublesome. It is better to check them before sowing than try to eradicate them when once established.

**VEITCH'S AUTUMN GIANT CAULIFLOWER.**—This is a variety of such extreme usefulness that we give it a note to itself. It is unique from September until December, and seed should be sown at once to give plants that will bear during the period named. It is by no means tender, and may be sown along with the Kale and Savoys.

**HERBS.**—Mint is strong and healthy, evidently much benefited by the surface dressing of manure put on it some time ago. Thyme and Sage are making fresh growths, and these are three herbs which should be grown in quantity by all. Mint is easily increased by dividing the roots. Sage and Thyme come readily from seed, and Tarragon, summer and winter Savorys and all other hardy herbs do the same. Sow now in light rich soil, and give established plants plenty of manure to promote luxuriant growth.

#### FRUIT FORCING.

**VINES.**—*Early Houses.*—Vines in all stages have been greatly benefited by increased ventilation and early closing with sun heat in lieu of incessant firing, which has been absolutely necessary for many months to maintain the minimum temperature. Excessive firing encourages red spider, particularly on Vines that are carrying full crops of Grapes through the winter and spring, as firing must be constantly kept up to secure the requisite temperature, and as these troublesome insects spread with alarming rapidity the usual remedies must be applied without delay. Some, when driven to extremities, resort to the syringe, but the application of water, even in the hands of the most careful, is liable to damage the bloom, soft water in some cases leaving a mark where the water hangs on the berries. Sponging the foliage is a tedious operation, but if done in time the Vines may be kept in good health until after the crop has been removed, and as future crops depend upon the preservation of the foliage, early attention to this work is imperative. A careful examination of the inside borders should be made, and if they are dry a liberal application of tepid liquid manure will be found a powerful aid to the Vines. Grapes now colouring fast will require abundance of warm air by day and night, with plenty of moisture on the paths, walls, and mulching. Gradually reduce the night temperature as the Grapes ripen, keeping the atmosphere dry and cool where they have to be kept any length of time. When approaching ripeness moderate fire heat will be required to keep up a circulation of rather dry warm air by day and a temperature of about 60° at night. Guard against excessive dryness, as early Grapes with ventilation require much more water than late ones. Gradually remove the remains of fermenting materials from outside borders, leaving a good mulching of the most suitable—*i.e.*, that only partially decayed, for the protection of the surface roots, and allow them to have exposure to the summer rains, which will wash in the fertilising elements of the manure, and stimulate the Vines into the production of new laterals after they are relieved of the crop.

*Midseason and Muscat Houses.*—Thinning must be attended to in the case of the free-setting varieties as soon as the berries are set, but Muscats should be left until the properly fertilised berries take the lead. If a large percentage of the surplus bunches were not cut off before they flower no time must be lost in getting them removed, and laterals that have been allowed to ramble may be stopped, tied, and regulated in accordance with the uncovered space at command. Give inside borders a thorough soaking with tepid liquid manure, and mulch with short manure, it being preferable to use the droppings fresh from the stables spread over the whole surface in order to afford the Vines the benefit of an ammonia-charged atmosphere, but care must be taken not to overdo it, or the ammonia will be too powerful for the tender foliage of the Vines. It may be obviated if there is any danger of this by admitting a little air constantly at the top of the house. Ventilate early, and increase it with the rising temperature, closing sufficiently early for the temperature to rise to 85° or 90° with plenty of atmospheric moisture. Before night a little ventilation given at the apex will allow the vitiated air to escape, and prevent the deposition of moisture on the foliage.

*Late Houses.*—The passing month, though better than its predecessors, has been cold with little sun, and though there are complaints of bad

breaks, which are attributed to last season's dryness, late Vines have, as a rule started well, and are now making good progress. Some complain, however, of the tendency to the production of tendrils or loose bunches, a sure sign of imperfectly ripened wood, and in some instances the shows are not as good as usual; but the bunches are compact, and these, as a rule, are just the kind to be wished for keeping, as the footstalks of the berries are usually stout and keeping fresh up to June. In order to prevent the disposition to run into tendrils, the late Vines should be started earlier, and be ripened earlier with more fire heat if necessary in early autumn, so as to secure thoroughly finished fruit and perfectly matured wood. As a means of correcting it the shoots should be tied down to the wires, and stopped to within three or four joints of the fruit, the best time for performing this being the latter part of a fine day when the growths are limp, and keeping rather drier and warmer by day. Fertilise Muscats, and other shy-setting varieties every fine day, when the temperature has reached the maximum, having removed the greater part of the surplus bunches prior to their coming into flower. To have Gros Colman, Gros Guillaume, &c., thoroughly ripe and fit for use before Christmas the fruit should now be setting in what ought to be termed a midseason rather than a late house, as these require more water and a longer time to ripen than other Grapes.

Newly planted Vines should now be well mulched and liberally supplied with water, closing early with plenty of atmospheric moisture. Allow laterals free scope, but those from the lower part of the canes should be kept closely pinched, but the old leaves must be carefully preserved.

Look well to pot Vines, and if late planting is contemplated no time should be lost in making the needful borders and getting the planting done. Large-growing plants from pots or turves may be transferred at any time, but the earlier the better, as Grapes cannot be obtained from badly ripened wood, neither will half-ripened canes, when cut down, make such clean short-jointed growths next season as others that have been properly ripened and rested through the autumn.

*Melons.*—This fruit in the early house or hotwater-heated pit will be ripening, and will need a drier yet buoyant atmosphere in order to secure good flavoured fruit; hence the advisability of ventilation at night, as pent up air is not only against the colouring and flavour, but is likely to cause the fruit to crack. Maintain a night temperature of 70°, ventilate at 75°, and increase it as the temperature rises. Close the house at three to half-past in the afternoon. Add more soil to the hillocks as the roots push through the sides of the mounds, which must be repeated at intervals until the allotted space is filled. Do not allow young plants intended for planting to become root-bound before being planted, or they become stunted and rarely make a free growth afterwards. Any that are likely to get into this state should be shifted into pots a couple of sizes larger than those they are at present in, in order to keep them in steady progressive growth until the hillocks in the house, pits, or frames are got ready for them.

## THE BEE-KEEPER.

### INITIATORY INSTRUCTIONS.—No. 3.

PREVIOUS to supers being placed on the hive they must be fitted with comb foundation; the narrower the better it will be, as in many cases the bees do not pare down the sheet of wax, the neglect of which makes it unpleasant to the consumer of the honey. Sheets made from native wax is superior to any foreign sample I have yet seen. Bee-keepers should secure their own wax and have it made into sheets.

Divisible supers, for convenience in every respect, are what should be used, each bar having a groove in centre  $\frac{1}{8}$  by  $\frac{1}{8}$  of an inch. After straightening the strips on a table grip these so that they be not twisted, slipping them into the groove, then from a glue pot filled with wax fully melted, and the water boiling, take a teaspoon, keeping it in the wax until it is well heated, without which the wax is cooled, sets upon the spoon, and prevents the work being done satisfactorily. Now take each bar in the left hand, and holding it at an angle so that the wax will keep close to the sheet and run down the groove from one end to the other, then repeat on the other side. Be sure and fill every part of the groove on both sides. This must be adhered to with frames as well; by doing so it induces the bees to build the comb close to its foundation, and prevents the bees interposing small pieces of comb and deviating from the straight line, which destroys the beauty and symmetry of the super. The same instructions apply to the fastening of comb foundation in supers where the bars are secured. If full sheets are determined on, unless they are steadied they are liable to collapse; to prevent them doing so, nail little strips of wood to a piece about five-

eighths of an inch square, in size and number to pass between every bar to the full depth of the sheet or box. This rake-like contrivance is effectual in preventing any collapse, gentle handling and keeping in the natural position all deep foundation and newly made combs is the imperative duty of all bee-keepers.

When supers are placed on the hive, be sure it is smooth and free from any obstruction whatever; and as it is always advisable to pass a cord between super and super as well as the hives to sever any attachments of comb, it is well to put a very thin wedge at each corner between each division to allow the cord freedom of passage—a thick shaving is sufficient. It is very advisable to gum a strip of paper at each junction, or get a ball of tailor's reeds and wind a strip or two round each and fasten with a pin. It is always most pleasant to look at a clean super—a rather difficult thing, as the bees soon discolour everything they travel on, but the bee-keeper must use his best endeavours to preserve its pristine cleanliness. And here I may observe the Stewarton deep hive possesses this advantage in the highest degree, a matter of no little importance in bee-keeping, not only to the man who sells his honey, but to those who make it a pride in showing to the greatest advantage, along with flowers on his dining table, a magnificent super of honey made and gathered by his own bees, and perhaps from his own flowers. Then what a pleasure it is to both the giver and recipient when a handsome super is made to change hands as a present at a season when these are fashionable. These are the people I would urge to turn their attention more to keeping bees. Country gentlemen who have accommodation and means to keep bees are numerous, and yet how few, comparatively speaking, keep them! and where there is a family, how useful would the produce be to them, not speaking of the interest to them otherwise, as well as the lessons which might be of great benefit in after life. But I am digressing.

It is important that the junctions are made secure, as bees will not work where a draught is until all is close, so that the bee-keeper doing this saves the bees much labour in closing up with propolis or wax.

A good supply of calico is handy for the first layer, which keeps all clean, next either dried grass or any kind of woollen cloth, new or old, heaped on until the bees will not be affected by any change of temperature. A uniform degree of heat inside the hive is one of the best means towards a successful issue. In covering supers it is necessary to have them so that they can be easily inspected either from the windows or from between the bars at the top. The bee-keeper must, therefore, keep that in view, and arrange the coverings that a peep can be had at the super to see the progress made without disarranging the whole coverings, and let every manipulation be made from the back of the hive; never stand in front unless when it cannot be avoided.

Whenever, from any circumstance, these instructions cannot be carried out use your own judgment in the matter what should best be done, remembering at all times that Art can never excel Nature. Always err on the safe side in whatever you do. Have your hives extra strong rather than weak, and never depend on more than one week's fine weather at a time unless the prognostications clearly indicate a longer continuance. Never allow bees to loiter, crowd out, or fan much at the door. A little ventilation will ease the bees of the trouble and carry away unaided by them all vitiated air and excessive moisture; that is what we call assisting nature. A very little experience soon shows by the action and activity of the bees whether more room is required or not. Whenever this is observed by fewer bees working lose no time in giving more super room, and never attempt to super hives unless the body is of sufficient size. As before mentioned, rather put two hives together and have one strong rather than two weak, but if my instructions are attended to weak hives will be the exception.

Whenever a super is observed to be completed remove it at once. If the under one or ones, lift the topmost ones off in

a body first, then take the thickish brown paper kept flat between two boards, and recently painted with crude carbolic acid, and of the right lengths, insert these in each division (after you have passed the cord through and placed a sheet of thick cardboard on the top of the super impregnated with carbolic acid, which should be slid on immediately the upper ones are removed so as to clear the bees away) inserting the one after the other as the cardboard is slid off. If this work is properly done every bee will have left the super before you have got all the papers withdrawn, dispensing altogether with smoke, and is better for both bees, honey, and combs. Taking off supers and otherwise manipulating with bees under the influence of carbolic acid is mere child's play, and is in happy contrast to the older systems, where the operator had to be not only veiled, gloved, and armed with a bundle of smoking rags or smoker, rendering him when so equipped but a clumsy operator. The most difficult task was removing the bees from the super, not speaking of the great risk of infuriating the whole bees in the apiary to sting all within reach, and be despoiled of the contents of the super besides. Happily for bee-keepers there need not be such risks now troubles now. I must here leave the beginner to act according to his own judgment and good sense, seeing that it is hidden from us what the future is to be, or how long the honey glut will last, but it is certain, however, to end whenever rain approaches, or after a few weeks' drought, both being alike fatal to a honey glut. I have only experienced two seasons that bees gathered honey from Clover a second time after it had been once stopped, and only once have I witnessed bees working on Red Clover, black bees and Ligurians alike, recorded in this Journal about 1863.

After the honey season is past, whether in view of a future Heather harvest or not, steps should be taken to depose the reigning queen and supersede her by the introduction of a young one. A good plan to do this with hives of the Stewarton type is to withdraw all the slides on top of the upper box, using the same precautions with cardboard as advised with supers, and empty the upper box of bees in the same manner. If it is filled to a cell better to keep it off altogether and use the honey, using a screw presser and a drainer for the purpose of getting it separated from the comb and having it a pure sample. If it is necessary to do this repeat the operation with the next box. When it is clear of bees place the young queen caged over or between the combs, cover up and place on original stand, now remove the under box, place it on the top of some empty ones and drive the bees down by former process. When empty prune out superfluous drone comb and replace it on the stand underneath the queen. Many of the adult bees will have returned to their old site gorged with honey and in a fit state to fraternise with young queens, which may be liberated in twelve to twenty-four hours after. The old queen along with the remaining young bees will now be in the empty hive, but owing to their greater paucity now the queen will be easily found, when she should be removed and the remaining bees shaken on to a sheet of cloth or metal having a ladder attached reaching to mouth of the hive, when the bees will immediately ascend and enter their hive. All this may be done without receiving a single sting or provoking any disturbance whatever. After a queen has been much taxed laying to keep up the population of strong hives during the spring and summer up till July, it is absolutely necessary to dethrone the queen regent during that time if a full gathering is to be expected subsequently at the Heather. Another thing to be borne in mind is that from the time the first egg is laid till the first bee works a space of about thirty-six days must elapse, but at the middle of that term the hatching bees liberate the older ones from the internal duties of the hives to the field work, the young bees taking the place of their elder sisters in the nursing of the young bees. In my next article I hope to be able to give substantial proof in some matters of the superiority of the Stewarton hive, specially as to wintering.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

TO CORRESPONDENTS.—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

Tea Roses for Walls (*F. J.*).—We think you penned your letter of inquiry before you read the Journal of last week, and we have now only to direct your attention to the article of "D., Deal," on page 316. Other good varieties are Souvenir d'Elise Vardon, Madame Lambard, and Souvenir d'un Ami, which differ in colour from those named in the notes referred to.

Chrysanthemum segetum (*A. McM.*).—The experiments you propose making will be interesting, and if you succeed in obtaining any crosses of a distinct character you should send specimens with particulars to the Scientific Committee of the Royal Horticultural Society, South Kensington.

Dutch Bulb Growers (*A Subscriber for Many Years*).—The following are the names, placed alphabetically, of six of the wholesale bulb-growers in Holland, who supply the retail firms in Great Britain:—Byvoet Brothers, Hillegom; J. H. Kersten & Co., Haarlem; J. Polman Mooy, Haarlem; F. Van Velsen & Sons, Haarlem; F. & H. Van Waveren, Hillegom; and M. Van Waveren & Sons, Hillegom. In reply to your other question, write to Mr. Louis Van Houtte, Royal Nursery, Gendbrugge, Ghent, Belgium.

Cucumbers Scorching (*H. H.*).—If the glass is not very inferior—that is, unusually full of lens, we think there must be some mistake in the ventilation and water supply both in the soil and atmosphere. Are you certain the soil is sufficiently moist, not near the surface alone, but below? Examine it, and if at all dry make it thoroughly moist throughout. With good attention in those respects—that is, early ventilation and adequate moisture, you ought to have no difficulty in preventing the foliage scorching, with the rays of the sun subdued by a sprinkling of thin whitewash applied to the roof outside with a syringe. If you have a thick covering of whitewash on the glass wash it off and try the plan recommended. We feel certain that one cause of the evil is an insufficiency of water. A very great quantity will be required in a span-roofed house of the kind shown in the sketch you have enclosed.

Grapes not Colouring (*Desideratum*).—Want of colour is generally the result of inadequate support. The Vines have either been overcropped, the border is too poor, or the root-action defective through the coldness of the soil or drought. It is doubtful if lime would be of any material benefit unless the border be very rich indeed, then a good dressing would be certain to do good. You give no particulars whatever about the border, but simply leave us to guess at its state, and we are inclined to think that very copious applications of tepid liquid manure will benefit the old Vines. Your other question is unanswerable. Either work fairly at the verges yourself for an hour, or set a good man at work for a time, and you can soon ascertain how much ought to be done in a day, and decide on a fair price for any given length. Everything depends on the condition of the verges and the soil in settling the question.

Woodlice (*R. R., Belfast*).—We have previously stated that woodlice have been caught in thousands by placing some partially decayed and dirty old boards face to face, and covering these with litter where the pests abound. Smooth new boards are of no use, but the older they are the better, and there should be space for the woodlice to enter between them. They should be examined every morning, taken up, held like a trough, and the contents emptied into a tank or vessel of water. A vinery containing Mushroom beds swarmed with woodlice last year; tens of thousands were caught in the simple manner described, and this year there are few to be seen. It is a certain mode of riddance if properly carried out.

Wireworms—Tomatoes (*An Old Subscriber*).—As the Asters will not be ready for planting for some time, we should at once plant the ground with Potatoes, putting any sorts of old tubers in thickly, and when the growths are above ground, or just before the Asters are ready for planting, dig out the Potatoes carefully and burn them, as they will in all probability contain the greater number of the wireworms now in the soil. Carrots

will do as well. We have known this plan to answer admirably. Before planting the Asters give the ground a heavy dressing of soot, as this will be distasteful to the wireworms and a good manure for the plants. We saw both the varieties of Tomatoes you name with single stems 15 feet high last year, and you ought to have no difficulty in covering a trellis with them in your Cucumber house, planting in enriched turfy loam, making the soil firmer than is generally used for Cucumbers.

**Mushrooms (G. M.).**—The Mushrooms you sent are safe enough, but not good. We at first thought they were samples of *Agaricus campestris* var. *silvicola*, but we do not think so now. We believe them to be ordinary Mushrooms changed in colour by ammonia from the bed, and conclude that either the manure has not been sufficiently purified or the casing of soil is either too thin or has shrunk, leaving small fissures, so small perhaps as not to be very discernible. In a long house in which additions of three or four yards are made of fresh materials at intervals of three weeks for securing a successional supply of Mushrooms, there is almost always a row of silvery-gilled Mushrooms across the older portion of the beds after each addition of fresh manure to the end of the row, but those following afterwards are of the right colour. We have a specimen before us now with the gills whitish except where the edge has turned up, as it does with age, and there the gills are pink. The turned up portion escaped the direct action of the ammonia rising from the bed. Try the effect of another covering of loam and do not let the surface of the bed get dry, and you may possibly effect a change for the better with your crop.

**Hedge Unsatisfactory (Cambridge).**—It is almost impossible to induce a thin hedge to thicken at the bottom without reducing its height. Improvement may sometimes be effected by cutting down some of the growths which form the hedge without materially impairing it as a screen; and some growths may occasionally be spared for "laying"—that is, cutting them almost through at or near the base, so that they can be bent down and affixed in position where required. Notes on hedges will be found in another column from a contributor who has had great experience in the work on which he writes. Hedges often get weak through poverty of soil and drought, and they invariably suffer in that respect under trees. The only remedy in such a case is to break up the ground, so that strong and copious supplies of liquid manure can be directed to the roots, afterwards top-dressing with a thick layer of good manure. Where it is convenient to do so strong young plants may be put in for forming a better base, providing enriched soil, and keeping the roots moist.

**Thuja Lobbi for Screens (R. W.).**—Without doubt this is one of the best Conifers for forming ornamental hedges and valuable sheltering screens, though it would be some time before getting tall enough for protecting standard orchard trees. It is very elegant in growth, and retains its bright green colour in winter. It grows freely in good loamy soil, such as is suitable for fruit trees. One row is sufficient for forming a good screen. We know of a number of trees that were planted 6 feet apart all grown together now forming a beautiful hedge 20 feet high and 8 feet through at the base. The distance for planting depends entirely on the size of the trees and whether a close hedge is desired at once. If a space be allowed between the trees equal to their diameter they will soon touch each other, and every alternate one can then be removed if desired to form another screen, or they can be left and trimmed to form a close hedge. You will find much of interest in respect to this fine North American tree in Veitch's "Manual of the Coniferae," in which it is illustrated. There is some confusion regarding its nomenclature. Its correct name is no doubt *Thuja gigantea*, but the Conifer widely known under this name is *Libocedrus decurrens*; but we think the Conifer you inquire about is sold as *Thuja Lobbi* by most nurserymen. It was introduced by Messrs. Veitch & Sons in 1853 through their collector, Mr. William Lobb, hence its name.

**The Morel (Kittie).**—The specimen you have sent is undoubtedly the Morel (*Morchella esculenta*). From the complaint that Dr. Badham makes, that in England this fungus is only known as an article procurable at the Italian warehouses, we augur that he has not been brought up among the thrifty housewives of Yorkshire. In the kitchens of that county, at any rate of the northern and western divisions of it, a string of Morels pendant from the ceiling is as familiar an object as a bunch of Sage twigs, or bundles of Thyme; and the heads of the household complain of the cook's neglect if she omits the Morel flavour in certain sauces. As children we knew the plant at sight, and brought it home whenever we encountered it in our walks; and the poor knew it also, for ever and anon the women who gathered Cowslips for the wine-brewing would bring a few in the corner of their basket, and plead for an extra shilling for the "Jew's Ears," as they were pleased to call the Morel. In Germany the excellence of the Morel was well appreciated, and, finding that it flourished the most luxuriantly on wood ashes, it became a regular system to burn down a portion of the forest annually to secure a crop of Morels. This custom was stopped by an edict of the Government, and thus legislation was turned against the fungi. M. Roques gives some receipts for the dressing of the Morel, which our readers may find serviceable:—"1st. Having washed and cleansed them from the earth which is apt to collect between the plants, dry thoroughly in a napkin, and put them into a saucepan with pepper, salt, and Parsley, adding or not a piece of ham; stew for an hour, pouring in occasionally a little broth to prevent burning. When sufficiently done, bind with the yolks of two or three eggs, and serve on buttered toast. 2nd. Morels à l'Italienne.—Having washed and dried, divide them across; put them on the fire with some Parsley, Scallion, Chervil, Burnet, Tarragon, Chives, a little salt, and two spoonfuls of fine oil. Stew till the juice runs out; then thicken with a little flour; serve with bread crumbs, and a squeeze of Lemon. 3rd. Stuffed Morels.—Choose the freshest and whitest Morels, open the stalk at the bottom, wash and wipe them well, fill with veal stuffing, anchovy, or any rich farce you please, securing the ends, and dressing between thin slices of bacon. Serve with a sauce like the last."

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once.

(C. N. L.).—1, *Narcissus incomparabilis aurantius plenus*; 2 resembles a *Grevillea*, but cannot be determined by the leaf alone; 3, We do not recognise; 4, *Polygala Dalmaisiana*. (Earn).—1, *Cœlogyne barbata*; 2, *Cœlogyne ocellata*; 3, Will be named next week.

**Bees (Jacobis and A. E.).**—We have forwarded your letters to "A Lanarkshire Bee-keeper," and requested him to attend to them through the post.

## COVENT GARDEN MARKET.—APRIL 28TH.

Trade falling off, and prices of house fruit lower.

### THE FUTURE OF FARMING.

"AGRICULTURE, if it is again to thrive in islands, must begin at once to walk arm-in-arm with science. Thus far, the vast majority of English farmers have learnt their business by rule of thumb. Most of them have been brought up on farms occupied by their fathers, and when they succeed to possession of the farm they work it on the very same lines

laid down by their predecessors. In every other trade and profession some skilled training is deemed necessary to insure success in the crowded crush of modern times. Alone, however, among our pliers of industry the farmer generally sets to work without knowing more of science than the pig he drives to market. The days are at hand when good farming will depend upon an accurate acquaintance with chemistry, mechanics, meteorology, botany, geology, and many other sciences."

While not perhaps agreeing with every word of our quotation from an article on agriculture recently published in a daily paper, yet thoughtful earnest men will admit the truth and force of the general statement, and own that we must combine science with practice if we are to achieve any real improvement in farming. Is, then, farming capable of improvement? This is a question of so much importance that we may well ask our readers to give it due consideration, to weigh well their own practice and its results, and to see if faults of the past may not be avoided in present efforts for improvements in the future. Not lightly would we offer advice to men whose efforts are so heavily handicapped by a depression which deepens in intensity; but when they seek for relief in the form of a reduction of rent, while making just concessions, every possible effort at improvement in practice may fairly be required on their part.

Sound judgment and common sense enable a man to seize upon every coign of vantage, to miss no opportunity of improvement. Lessons are frequently before our eyes, their teaching is plain and unmistakeable; well will it be for us if we can understand and apply them to practice. For example, a few hours before writing this article we were at a large cattle market, where lambs were sold at 46s. apiece, and well-bred ewe hoggets at 63s. apiece. But there were very few lambs that reached that high price, and the high-priced hoggets were all from one famous flock-master. Surely the lesson here was not hard to understand! If early lambs, by careful tending and judicious feeding, command a price superior to the average of an ordinary hogget, one should make an effort to rear some; and if the rearing of early lambs was taken up so generally as to bring down prices, yet a falling off of 10s. apiece would still leave a fair margin of profit. Then, too, of well-bred ewe hoggets there should be more. If we keep sheep at all, why not have them as well bred as possible, if that represents a greater value—a higher profit? To do this we must be prepared to give much time and patience to careful selection in the formation of a flock. No man achieves fame as a flock-master by the mere expenditure of money. Of course there must be a certain outlay of capital at the outset, but that must be followed by selection and good management. In a recent discussion of the effects of the depression an unanimous opinion was expressed that if a farmer were driven by hard times to sell his ewe flock bankruptcy soon followed. Greatly do we regret seeing so many farms without sheep this spring. It may be said that scarcity of food compelled farmers to part with their flocks last autumn. Whatever was the cause, the effect must be disastrous both for tenant and landlord, pointing as it does unmistakeably to low farming. However low the price of mutton may be, cling to the sheep say we, and do not forget how much they do to sustain fertility in the land over which they pass. Sheep certainly must have a prominent place in the future of farming.

Cattle naturally occur to one in thinking about the best means of imparting fertility to the soil with a view to profitable farming. To keep cattle solely for such a purpose is decidedly wrong. Farmyard manure manufactured in cattle yards is certainly the most costly manure we can have. The expense of tending the cattle, carting the manure to heaps, which are usually turned over once, re-carting and spreading upon the land; all this mounts up to a serious item of expenditure, apart from the value of the straw used. "To farm well keep plenty of live stock" is a remark that is common enough in the mouths of farmers, and one still hears

it made with an amount of assurance which, at any rate, betokens confidence on the part of those who thus pin their faith to the muck heap. In farming of the future farmyard manure will cease to hold this prominent position. A certain quantity will probably still be used in root culture, but for general purposes artificial manures, green crops, and sheep-folding must be adopted. The prejudice against artificial manures will cease when it is made plain to farmers that by the correct use of them a saving can be effected and profits increased. All this will take time, for before the matter can be fully understood some knowledge must be had of the nature of soils, of the elements of plant food required for the full development of each crop, of the properties of chemical manures, and of the mixing of them in due proportions. Let the leading spirits of local agricultural associations remember that agriculture as a science is far from perfection, and that it falls within the scope of their society to make trial stations for the mutual benefit of its members.

(To be continued.)

#### WORK ON THE HOME FARM.

At length we have begun folding the ewes and lambs upon Rye. A new fold is prepared daily for them, into which the lambs run forward through lamb gates, the ewes following them one fold behind, Mangolds being given them there with the Rye, chaff, and some lamb food. Fresh lamb food is put into the troughs for the lambs in the forward fold when they enter it at about 3 P.M., the flock being taken out of the folds upon grass early in the morning. Greedily as the lambs eat the Rye they have no scour, the lamb food keeping them sound and lusty. When the nitrate of soda was put upon the Rye a small piece was left undressed with it in order to test the power of the manure. Nothing could be more satisfactory, the undressed part being comparatively meagre in growth, and of a pale green colour that looks positively sickly beside the deep green hue and rampant growth arising solely from this application of a hundred-weight of nitrate of soda per acre. The lesson though simple is clear and unmistakeable, and it might well be shown to a beginner as the first sure step in the use of chemical manures. Turning from the Rye to a piece of Winter Oats close by, we have before us an immense stride in such knowledge, for here we have an illustration, living and growing more forcible daily, of the immense value of the teaching of Professor Jamieson as evolved in the experimental stations in Sussex during the last five years. The Oats were sown last autumn with a half-dressing of home-mixed manures, the other half-dressing being given early this spring. The nitrate of soda used in this mixture has been considered a doubtful advantage, but several years' experience enables us to say that it is invaluable for the promotion of such a robust sturdy growth at once as enables the plants to withstand the effects of very cold weather, and there can be no question that the small quantity used is soon absorbed by the plants. Just as the growth starts into full activity again in spring comes the second dressing. The full value of the manures can only be realised in July, but even now we can see remarkable results. Another nine-acre field of Winter Oats was in Rye Grass last spring, the ewe flock were put upon it with cake and Mangolds, it was then ploughed and sown with White Mustard, as it was notoriously poor. The Mustard was ploughed in, the manure mixture sown with the Oats, and a spring dressing has been given. We shall watch the result closely, and we hope to gain a useful lesson from it, both for our own benefit and that of our readers. We have the harrows in use upon corn thick with seedling Charlock, and the hoes must now be briskly at work.

#### REMARKS.

18th.—Dull and cold, with occasional showers.  
19th.—Fine, bright, and warm.  
20th.—Dull morning; fine and bright afternoon and evening.  
21st.—Cloud and sunshine in morning; the rest of the day dull.  
22nd.—A fine bright day.  
23rd.—Fine, bright, and warm, but with a rather penetrating easterly wind.  
24th.—Dull early; wet from 9 to 10 A.M.; fine and bright after 11 A.M.  
On the whole a bright, warm, and pleasant week. Temperature slightly above the average, and nearly 6° above that of the preceding week.—G. J. SYMONS.

### THE COLONIAL AND INDIAN EXHIBITION.

**T**HREE great annual Exhibitions have been held at South Kensington, and have attracted some millions of visitors to London each year; but as it is obviously impossible to provide an indefinite series on so large a scale and sufficiently diversified to maintain the public interest, it appears very probable that the one announced for 1886 will conclude a gigantic and successful experiment. The Colonial and Indian Exhibition, which was formally opened by Her Majesty the Queen on Tuesday last, the 4th inst., was planned as an admirable successor to the "Fisheries," "Healtheries," and "Inventories," and one that by its scope and importance will create considerable interest throughout the British Empire. So vast an extent of the globe is covered by our Colonies and dependencies, such a variety of climate is represented, that a really characteristic display of their productions may be taken as an epitome of the world's industry. Anglo-Saxon energy and commercial aptitude have had a wide field for exercise and development, and visitors to the Indian and Colonial Exhibition will have an opportunity of judging some of the results.

A department with which our readers are most concerned—the vegetable products—is necessarily of leading importance at this Exhibition. The food imports to Great Britain are enormous, and as the home population increased so rapidly, it became necessary to encourage the cultivation of many useful plants in portions of the Empire where the climate is suitable, so that we should be less dependant upon the supplies of other countries. This course has been consistently pursued for many years, and with satisfactory results to the Colonies and the home country. A good proportion of the food products imported to this country now come from some of our dependencies, and the trade is rapidly increasing in many directions. Examples are afforded by Tea, Coffee, Cocoa, Sugar, Rice, and many others, the cultivation of which gives employment to millions of people in the East and West Indies, and which are shipped to England in vast quantities. In countries like India, where a great mass of the population is dependant upon agriculture for a living, the importance of a remunerative market for the produce cannot be over-estimated. For instance, it has been estimated that of the 180,000,000 male inhabitants of the country named 51,000,000 are dependant upon agricultural pursuits, and although the home consumption there is very great, in ordinary seasons there is also an abundant surplus for exportation. Some are also specially cultivated for sending out of the country, such as Opium, of which so much is purchased by the Chinese, but of the Indian vegetable products sent to this country one of the principal is Tea, something like 70,000,000 lbs., or a third of the entire supply, being received from the Indian plantations. Ceylon Coffee is another important production, an average of about 500,000 lbs. of berries being received here from that island. These are only examples, for many more might be cited with

reference to the West Indies, Australia, and other countries, but further particulars concerning them may be reserved to another occasion.

The Exhibition at South Kensington occupies the same buildings as the one last year, with a few minor alterations, but they have been rendered far more ornate, and in general appearance it will be the most attractive of the series. The galleries near the main entrance are devoted to East Indian products of all kinds, the central galleries are occupied with the Australian and other Colonial exhibits, the long gallery next to the gardens being appropriated to Canada. In connection with some of these an excellent idea has been carried out—namely, providing living representatives of the plants peculiar to the respective districts. For their reception spacious glass houses have been erected by Messrs. Dashwood & Co., Wimbledon, and Mr. S. Deards, Harlow, Essex, and they are being stocked with plants supplied by the principal London nurserymen and from the Royal Horticultural Society's Garden at Chiswick, where large numbers of Ferns have been received and grown for the purpose. In one or two of the trade collections, however, it is regrettable that plants have been introduced not strictly characteristic of the countries they are supposed to represent, and it seems as if the object has been to show all that succeed there in gardens, whether natives or not. This must be an oversight, and is certainly not due to any lack of typical plants, for most of the Colonial floras are exceptionally rich in species. Take the Cape of Good Hope for example; in a comparatively small district about 9000 species have been collected, including some of the most beautiful flowering plants that adorn our greenhouses—the *Ericas*, innumerable choice bulbs of the *Ixia*, *Sparaxis*, *Gladiolus* types, the pretty but neglected *Mesembryanthemums*, the useful *Pelargoniums*, from which we have obtained such an extensive group of decorative plants, and innumerable others. In Australia we have some very distinct forms of plant life. The *Acacias* are in strong force, the *Eucalyptuses*, the *Epacrises*, members of the *Protea* family, and hundreds of plants which are known in gardens as "hardwooded," somewhat delicate under culture, but the majority beautiful. From New Zealand, with a moister climate, we obtain many Ferns, but like some other islands widely separated from the mainland, the number of plants peculiar to it is proportionately great; thus of about 900 flowering plants discovered in New Zealand over 600 are confined to that country, 200 are Australian, and the remainder American. The total number of plants found and described in Australia and New Zealand together has been estimated at nearly 8000, and a good number of these have been introduced. The East and West Indian floras are especially rich in the most handsome of tropical plants, but except the Orchids these are not represented at the Exhibition by living specimens.

As at previous exhibitions an avenue runs at right angles with the gallery at the main entrance, connecting it with the Canadian Court at the upper part of the ground. It passes "Old London," facing which is now a great Indian Palace, affording a curious and interesting contrast; then a short distance beyond are two large glass houses, the one on the right devoted to plants from New South Wales, furnished by Messrs. J. Veitch & Sons, Chelsea, and the other occupied with Victorian plants from Chiswick. The latter is in a more forward state of preparation than any others in the Show, the Tree Ferns, *Todeas*, *Xanthorhæas*, and others having been very tastefully arranged by Mr. A. F. Barron. The fine *Dicksonias* received at Chiswick some time since have made excellent growth; the huge plants of *Todea barbara*, some of which are said to weigh 3000 lbs., are similarly healthy, and a series of little valleys and nooks have been formed that have a most refreshing appearance. In the New South Wales house are Palms, such as *Corypha australis*, *Areca Baueri*, numerous *Acacias*, *Araucarias*, *Eucalyptus*, *Banksias*, *Cordylines*, *Alsophilas*, *Gleichenias*, *Dammaras*, and *Cycads*,

with others, to which additional notes will be devoted another time. Mr. W. Bull, Chelsea, has a house of Queensland plants, which include some beautiful and valuable rarities, of which only a few can be mentioned. The curious Cycad with bipinnate leaves, *Bowenia spectabilis*, is notable; the majestic *Doryanthes Palmeri*, the Moreton Bay Chestnut, *Castanospermum australe*, *Davidsonia pruriens*, several Palms, the elegant *Alsophila Rebeckæ* and the fragrant-leaved *Eucalyptus citriodora*, reminding us of the well-known *Aloysia*, are some of the principal features. There is also an extensive rockery and aviary constructed by Messrs. Dick Radclyffe & Co. for Australian plants and birds, which, when completed, will constitute an attractive portion of the exhibits in this department. There are also in several of the courts large numbers of coloured plates representing the flowers of the different Colonies, wax models of the fruits cultivated, and an important series of Australian woods cut like volumes of books and arranged in a case.

The largest house of all is that intended for New Zealand vegetation, which has been constructed by Mr. S. Deards. It is 140 feet long, 35 feet wide, and very lofty, with curved lean-to roof, and will require an extensive collection of plants to fill it. These are to come chiefly from Chiswick, and will consist largely of Ferns, with *Dracaenas*, the native Flax, (*Phormium tenax*), and others. When furnished it will have a particularly handsome appearance, as a steep bank rising to the back will form a diversified rockery that can be well seen from the path below. At the western side of the Exhibition is situated the Cape of Good Hope house, which has been filled by Messrs. E. G. Henderson & Son, Maida Vale, London. At the present time this has the brightest appearance of any, owing to the number of flowering plants employed, such as *Ericas*, *Pelargoniums*, *Oxalises*, and *Richardias*, to which are added, for ornament only, *Hydrangeas* and *Musk*. Some large examples of the Elephant's Foot, *Testudinaria elephantipes*, are remarkable, one weighing 12 cwt. During the season we may expect a bright succession of flowers in this house, which will be one of the most attractive to general visitors. The Natal house is furnished by the same firm, including chiefly foliage plants and some of economic value, such as the Sugar Cane, Tea, Coffee, and others that have been found to succeed in the Colony.

To the right of the main entrance Messrs. Sander & Co., St. Albans, have a house that is to be devoted to the Orchids from India and the Colonies, and provision is being made for a most effective floral display. Suitable pockets and nooks have been constructed on the walls, and in the centre, of rustic woodwork, in which the plants will be arranged as naturally and informally as possible.

In other departments, as in the West Indian galleries, coloured plates of plants are numerous. In several there are enlarged representations of the most important native plants painted on the walls, while in the Canadian Court is a massive trophy showing all the principal vegetable productions of the Dominion, either dried or preserved in spirit. These are a few of the features that horticulturists will find most interesting, but the attraction will be greatly increased when the arrangements are more nearly completed, for at present there is much to be done. Popular as the other exhibitions proved, it is very probable that with a fine season this will obtain still greater patronage, and it should enable the Commissioners to conclude the series with a substantial balance.

At the opening ceremony on Tuesday, which was one of the grandest of its kind seen in London for some years, the floral decorations were very effective. In the entrance-hall this was particularly noticeable, brilliant groups of *Azaleas* and *Cinerarias* being arranged with a due proportion of Palms and Ferns, very tastefully disposed, and much less formally than is usually the case with such groups. In other portions of the Exhibition Palms were freely employed, imparting quite a tropical appearance to the avenues and galleries, while Mr. Ware's beautiful collections of Daffodils, Tulips, Primulas, and other hardy flowers in the conserva-

tory were greatly admired. Around the Prince Consort statue, above the large fountain, were wreaths of scarlet Zonal *Pelargoniums* and white Hyacinths, with a background of Box shoots. As regards the general Exhibition wonderful progress has been made in the past few days, and apparently little now remains to complete it. The weather was exceedingly fine, and the season was commenced with a large attendance of visitors.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 335.)

### PLANTS AND BLOOMS FOR MARKET.

THE demand for flowers has increased among all classes greatly during the last few years, and none excels *Chrysanthemums* either in a cut state or as dwarf plants for the market during the months of October, November, and December. They are grown in large numbers to meet the increasing demand, so suitable are they found to be as vase plants in towns where other plants at that time of the year are scarce, and those producing white flowers are most in favour. *Madame Desgrange* is an excellent variety for an early supply, followed by *James Salter*, deep lilac, and its white sport, *Lady Selborne*, which is much appreciated. Next comes *Elaine*, which in my opinion is the finest of all *Chrysanthemums* in purity of colour, substance, floriferousness, and duration of the blooms. *Sœur Melanie* is another grand variety, producing its white flowers freely. The best of the incurved section for cutting in large numbers is *Mrs. G. Rundle*, which, owing to the blooms being of medium size, can be used more conveniently for bouquets. *George Glenny*, pale primrose, is the same habit of growth as the former, and excellent for the same purpose where flowers other than white are required. *White Cedo Nulli* produces flowers in abundance, and being of good shape renders it extremely useful for cutting. The above are some of the best for producing flowers in quantities.

Various methods are adopted in their culture, but the following is one of the best:—Strike the cuttings in the usual way in February, top them when 4 inches high, and transfer them into 4-inch pots. The best position at this stage is in a cold frame, taking care to prevent their being drawn weakly; top the shoots again when they reach the same length. About the middle of May plant them out 3 feet apart on an open piece of ground, and if the soil is poor use some well-decayed manure. Should the weather be dry and hot during summer water the plants freely. Continue to top the branches till the middle of June: do not stake the branches upright, but allow them to lie on the ground. The last week in September cut around the plants with a spade, and in about a week lift them with a good ball of soil and plant as thickly as their size will allow in houses usually occupied in the summer with Cucumbers. The soil in which the latter had been growing will suit the *Chrysanthemums*, and save further trouble of preparing other compost. The advantage of not staking the branches upright will now be obvious, as houses like those named are generally deficient of head room; the branches will better lie on the beds, and will be near the glass also. When planted give a good soaking of water to the roots, and syringe the plants in the afternoon for a few days, and if they show signs of flagging apply a light shade until they have recovered from the check occasioned by the removal. It will be well to disbud to one flower on each stem on some of the plants, and by allowing all the flower buds to remain on others flowers of different sizes are obtained, which are very useful in making up wreaths or bouquets. When the roots commence penetrating the new soil give liquid manure freely to the plants, and ventilate on fine days. Plants grown in this manner yield abundance of flowers with but a minimum of labour as compared with the method of keeping them in pots all the summer, and the houses which are devoted to Cucumbers during the summer are generally available for the *Chrysanthemums* just about the time they are required.

*Mrs. G. Rundle* is particularly well adapted for this method of cultivation, its habit of growth being moderately strong and branching freely. *Elaine* is not so suited for this form of culture as the preceding, its habit of growth being too tall and upright, but for the production of blooms it is a charming variety. The following course of treatment answers the purpose well. Strike the cuttings in January, top them when 4 inches high, and continue to do so until about the 12th of June; early in the same month give them their final shift, placing two or three plants in an 11-inch pot. Each plant will have from twenty to thirty branches, from which remove all lateral growths as fast as they are produced, retain the first bud formed at the point of each branch, removing all other side buds. If the flower buds are not thinned the blooms will be poor in substance and "hollow eyed," and in cutting the centre flower which opens first many side buds will have to be sacrificed, as they do not

expand so early as the centre bud. Feed the plants liberally during the time the buds are swelling.

Snowdrop produces its flowers in masses, and owing to their small size they are very useful for buttonholes. It is best struck in February, topped twice, allowing all the stems to grow and perfect all its blossoms, 8-inch pots being large enough for this variety.

The best variety to flower in pots as a market plant is *Sœur Melainie*; its habit is dwarf, it retains its foliage in good condition for a long time, it is very floriferous, and, what is of great importance, its blooms expand together, thus making it very effective as a pot plant. Strike some cuttings in February and more in March; as soon as rooted shift them into 3-inch pots, placing them in a frame close to the glass, keeping the frame close for a few days. As soon as they are rooting freely into the new soil take out the point of the shoot; keep them sturdy by ventilating freely. Continue to top the shoots of those rooted in February until the middle of June. Transfer them into pots 6 or 7 inches in diameter the last week in June, and by this time the shoots will have broken from their last topping. Those rooted in March should be topped continually till the first week in July, and when they have broken into growth again place them into their largest pots, by this means a succession of flowers is obtained. Another method of growing them is in this way. At the end of April or early in May divide the old stools or plants of last year's growth, failing these use young plants of the current year's growth, place them out in good soil, allowing ample space between them, and about the 20th July take off the tops 5 inches long and insert them rather thickly in 4, 5, or 6-inch pots in a propagating case in a cool house in the same way as for cuttings early in the year, only in the present instance the temperature of the house is higher. Shade them from the sun for a few days till roots are emitted, gradually harden them and remove them outside on to a bed of ashes full in the sun; treat them liberally by supplying liquid manure freely to the roots. When the bloom buds show colour support the branches either by placing one stake in the centre and tying the shoots to it in the same way as *Mignonette* or *Bouvardias*, or place a neat stick to each stem, which is of great assistance to this variety, as owing to the weakness of its peduncles the flowers have a tendency to droop, but if separate stakes are placed to each shoot the blooms can be supported, the plants will be 1 foot to 1 foot 6 inches high. Another way to treat them is as follows:—At the end of June peg a few shoots down to the ground, when rooted take out their points, and when the first break occurs after topping cut them off and pot singly; these in small pots make useful little decorative plants.

If plants of the *Rundle* family are placed out in the same manner as advised and frequently topped till the middle of June, about the first week in August take off the points of the branches 6 inches long, placing six or seven in a 5-inch pot, treating them similarly to the last named, except that the buds are reduced to one on each shoot, these will then produce pretty little incurved flowers on plants 9 inches to 1 foot high. Dr. Macary, *lilac Japanese*, is a variety well suited to this treatment. *Elaine* is not a good variety to grow as a dwarf pot plant, it quickly runs up too tall, soon loses its foliage and does not open its flowers simultaneously, which as a market plant is a defect, but for growing to supply cut blooms it is unrivalled. The three varieties of *Cedo Nulli*, *Aigle d'Or*, *La Viege*, *Patience*, and *Flame* of the single sorts, and several *Pompon* and *Anemone Pompons*, are also suitable for cultivating as market pot plants. No doubt there are many others which are suitable also, but these are a few of the best, and the requirements of the neighbourhood with many other matters have to be considered before deciding upon two or three varieties to grow.

#### DWARF PLANTS.

The engraving (fig. 65) accompanying these notes represents a plant of *Peter the Great* 8 inches high, growing in a pot 3½ inches in diameter, producing one bloom, which measured 5 inches across. *Chrysanthemums* grown in this manner are not so often seen as their merits deserve, and they are well worthy of what little attention they require in producing them. They further show how adaptable the *Chrysanthemum* is for various purposes of decoration. These miniature plants are well suited for indoor decoration in vases or for standing on the side stages of the conservatory, where dwarf plants only are required. Attractive flowers can be had from plants growing in pots 2½ inches in diameter, but where larger blooms are coveted pots 4½ inches across are better; indeed, these are large enough for plants grown by this method for any purpose for which they may be required. From the first to the last week in August is the best time to take the cuttings. If they are inserted sooner the plants are apt to get too tall, and if taken much later the flowers are necessarily smaller. Where *Chrysanthemums* are grown for the production of large blooms some of the points

are almost sure to be broken off by various causes about the time stated, as, for instance, heavy rains, high winds, and birds alighting on them, shoots at this stage being very brittle. Such shoots should be formed into cuttings 4 inches long, and some may be 6 inches long. Dibble them firmly into sandy soil, using pots 2½ inches in diameter; water well to settle the soil securely about the cuttings, plunge them in a gentle hotbed, shading them carefully from the sun, syringe the foliage every afternoon of fine days, and by keeping the frame nearly close roots will be formed in about a month, when more air should be afforded, increasing the supply until the plants will bear full exposure without flagging. The best position for them at that stage of their growth is on a shelf close to the glass in a cool house. If it is desirable to have large blooms shift the plants into pots of the size previously named, using rich soil and potting firmly. By this method cuttings can

Fig. 65.—A Dwarf *Chrysanthemum*.

only be procured by chance, and perhaps the varieties available are not those which are specially required, but it is better to utilise those shoots broken by accident than to destroy them. Two other systems of producing cuttings I will describe. Where plants are grown by what is termed the "big bloom" method, instead of allowing three branches on each plant have four, and when the buds form on the points of the shoots toward the end of August the extra shoots can be topped and cuttings inserted. If the lower part of the same branch is cut off, the plant will be none the worse for growing four branches instead of three. Where a large number of dwarf plants are required the following is a good method of preparing the stock:—Insert cuttings in the usual way in January, pot the plants as required; do not top them, but train up four shoots from each plant at the first break, removing all other side branches as fast as they appear. Secure the plants to one stake during their growth. When the bloom buds form, as they will at the time named, cut off the points, insert them, and treat as advised for the others. Nearly all varieties are suitable for this method, preference being given to those which are not weak in growth, avoiding all that have slender peduncles, the stout erect growers being best, as they require no support when in bloom.—E. MOLYNEUX.

#### THOUGHTS ON CURRENT TOPICS.

IF I have not recorded any passing thoughts on the topics of the past few weeks it is not because there has been nothing worthy of comment, but rather because I have felt that space would be better occupied with other matter, of which, judging by a notification that has appeared, the

Editor has had as much as he could deal with. Perhaps he is in the same position now, and if so my jottings must wait their turn, as they have waited before—that is, if they are worth preserving for filling a blank that a few odds and ends may occupy.

I THINK a gardening paper is very much like a garden, or it ought to be—that is, the space should be occupied much in the same way in both cases, the greater part devoted to that which is essentially useful, a due proportion being accorded to what is mainly ornamental (though there is often great use in ornament), with a few patches here and there, with something just a little better than nothing for the sake of variety. I am content to plant these patches, light work being more to my taste than heavy digging, and short spells than continuous labour at the same task, whether in the garden or that reflex of it, the gardeners' paper.

I HAVE, perhaps, done every kind of work that is found in gardens, "single-handed" and upwards, from digging drains to dressing dinner tables, sowing Onions to potting Orchids, planting Vines to earthing Celery; and it is because of this that reading becomes enjoyable and writing pleasant. I never read an article without imagining the writer of it at work on the subject of which he is treating. I have in my mind's eye such general practicalists as Messrs. Abbey, Bardney, Iggulden, and men of that stamp (I think "men" is permissible) planning and working. I like to picture "D., Deal," tending and noting the properties of his flowers; Mr. Horner amongst his Auriculas, about which he writes so delightfully; Mr. Castle scrutinising the Orchids; "D." examining with painstaking care the tops of Primulas; and Dr. Masters, with philosophic instinct, dissecting their roots; Mr. Wolley Dod among the Daffodils; and Mr. Shirley Hibberd covered with dust in rummaging through ancient books in search of the life history of flowers. And when we further consider that such work and researches are to a large extent conducted for the benefit of the others, it is impossible to suppress a feeling of pity for those gardeners who do not read, and whose minds are necessarily swamped and stunted by want of exercise.

I HAVE been reading gardening literature for forty years, and am grateful to all who have given of their store of knowledge, and the more so because it is certain they have not become the poorer through the giving; nay, they have grown richer, for in searching for information to impart to others they have found that which, but for the effort, would have been lost to themselves. I would like young gardeners to think of this, and in their endeavours towards self-improvement not to trust to reading alone, but test what they read, as far as their opportunities allow, and record their practice and its results. That is the safe way to acquire sound knowledge. But there is the dreaded criticism. Let no one fear it, but remember that it has, more than anything, made our greatest representative men very much what they are. But I must curb my thoughts, and may not inappropriately draw up at an example of the working of what I have tried to impress.

JUDGING "A. L. G." solely by his writings, I am strongly inclined to regard him as a young gardener, and the younger he is the more do his articles redound to his credit. He has, by opposing the supposed views of one of the best gardeners, and an experienced writer, won his respect. As Mr. Bardney observes on page 316, our excellent critic "is not a mere imitator, but exercises his thinking powers, and strikes out a course for himself." We want more of such thinkers and experimenters. "A. L. G.'s" experiment, as recorded on page 290, on the evolution of ammonia through the action of lime, is interesting. I think I pointed out last year that the presence of lime in soil could be detected by an acid, and this is now corroborated; but I have used litmus paper instead of a feather dipped in vinegar to detect the escape of ammonia. May I venture a suggestion that ardent young scientists are sometimes apt to overlook the practical bearings of their experiments. The very evolution of ammonia that your correspondent regards as waste, I regard, in the case of manure-poisoned soil of either a Vine border or plot of ground under cropping, as a distinct gain. When Mr. Bardney found his Grapes improve so markedly after an application of lime; when the late Mr. Speed of Chatsworth found exactly the same almost magical change; when Mr. Taylor of Longleat found lime of such service, they surely did not do wrong in applying it. The ammonia then liberated was absorbed by the crops; it was sealed before. The Vines were in the condition of a hungry man who had lost the key of his larder. The lime, in the instances referred to, was the key to the nutriment locked in the earth, and it was more, for it was food in itself that was needed by the Vines. Let growing crops be experimented with in rich soil, and a reasonable amount of salts of ammonia applied, and there will be no such waste as must follow when an excess is applied to bare soil. The crops will take care of that; and further, if 10 per cent of lime and 1 of sulphate of ammonia, which is enough for good loam, be mixed with soil and covered with an inch or two of damp earth, there will not be the waste that was found in the cannister experiment, and even sensitive reddened litmus paper will scarcely be tinged with blue. The excess used by "A. L. G." was waste, as it always is, and must be under such circumstances. The practical point is this. If a lady wants a sniff of smelling salts to revive her in a heated room, is she to refrain from drawing the cork because a portion of the ammonia may escape into the air?

I THINK it is possible Mr. Bardney may have applied more lime to his Vine borders than was absolutely necessary. It is difficult to determine the exact minimum, and lime is cheap; but it is certain he did not use too

much when he cured clubbing in the kitchen garden and made the land produce at the least fourfold that it did two years previously. Mr. Bardney has many visitors. I have been one of the units and seen the change effected in the Grapes and the Cabbages through the application of lime to limeless soil. I have examined Grapes in many gardens and from Vines grown in nearly all sorts of soil, but never found them stoned like the last I examined at Norris Green. I thought then rather too much lime had been used, though on that point I may be wrong, for the quality and flavour were superb.

I FEEL sure "A. L. G." will not object to my "treatment" of the case. I have certainly no wish to prove him wrong. That is not my object at all; but it is necessary to refer to the expression of his belief that "in sandy soil where lime is deficient bones will furnish all the lime necessary." They may, but at what cost? The bones used at Longleat did not; nor would half-inch bones have done so if four times the quantity had been used. Mr. Taylor gave the necessary lime in a ten times cheaper form than could possibly have been applied in half-inch bones. Let me here say I do not believe very much in the economy of bones in lumps. The proper mechanical condition of soil can be effected in a cheaper way; for instance, with charcoal, lime rubble, and crushed bricks. The most economical and effective way to apply bones is in powder, and the finer this is the better, steamed bone flour having the advantage, because it can be ground finer than that from raw bones. I believe a great virtue (but not the only one) of Jensen's Fish Potash manure consists in its fineness. I have not seen Mr. Thomson's famed Vine manure nor heard its described, but I venture an opinion that it is not in such large particles as "half-inch bones."

I MUST have just one more sentence about lime. Your correspondent in alluding to the per-centage of lime in fertile soil, asks if it does not occur to me that it is in its carbonate form? Certainly. It could not very well be otherwise, and I am not aware that it is in the power of man to prevent lime that is slaked, spread on the ground, and lightly pointed in absorbing carbonic acid, and what is that but making chalk, which "A. L. G." prefers? It is the only practical way in which chalk can be procured in many districts, and it is very certain that lime as prepared and applied in the manner indicated is not pure. There is not, in my opinion, nearly so much difference between the practical gardener as represented by Mr. Bardney, and the scientific gardener as represented by "A. L. G.," as at first sight appears. I do not mean that the latter is not practical as well as scientific, and the former not scientific as well as practical, but merely refer to the predominating characteristics. There has been a misunderstanding of circumstances and terms, but no harm has resulted through that, and we are all, perhaps, just a little wiser than we were three months ago.

As to manuring Vine borders until they become a mass of humus it is, I believe, a mistake, and if lime be not added such borders become practically effete. Vine borders, in not a few instances, are buried with wet manure at the wrong time—namely, in winter, making them sodden then and keeping them cold in spring. A lighter and drier covering is better for excluding frost, and the rich dressing is the most effective as a conservator of moisture in hot weather, and as preventing the sun and consequent drought driving the roots downwards. Soil as wet as a puddle during the cold months and as dry as a lime basket in the hot ones is utterly wrong, yet that is the actual state of hundreds of Vine borders. Support can be given to Vines far more effectively than in the form of heavy winter dressings of rank farmyard manure—namely, by approved concentrated or so-called "artificial" fertilisers, and more of these will be used in the future than in the past in gardens and on farms alike. Of all the fields open for useful thought this is the widest one I know, so wide that I dare not even enter it at the present time; and in leaving it let me express a hope that gardeners read attentively the farm articles in the Journal, for in them I often see most valuable information. Their underlying principle is this—good tilth, good seed, no weeds, and the greatest amount of immediately available nutriment applied in the smallest compass, and in proportions best adapted for respective crops. Let cultivators master that principle, and the so-called worn-out land of old England will yet be made young again, and its food-yielding resources enormously increased.

I WAS rather sorry to see that a "Young Practicalist" made a slight mistake on page 250 in his critique on science *versus* practice in horticulture. It appeared on the 1st of April. He had a very good case, but made a stronger one for opponents by accepting as facts certain statements which he believed authentic. There is perhaps a natural disposition to give credence to rumours that appear to sustain a preconceived theory. There is also a danger of young reformers using the sledge hammer too freely. At the same time I cannot help regretting that the "Young Practicalist's" position does not admit of his discussing the subject further. Britishers ought to be the last persons in the world to fear competition. They penetrate everywhere and compete in all nations, in many instances with great success. It is as futile as it is discourteous to speak disdainfully of "foreigners" as a body. There are as great-minded and good-hearted amongst them as with us, and on both sides individuals that cannot be regarded as patterns to follow. Let us excel the best of them if we can. International jealousies are dying by degrees, and the sooner they are all buried the better it will be for the world. At the same time I am emboldened to say that nowhere is better all-round gardening to be seen than in this country as conducted by natives so wanting in "accomplishments." Let young men strive for higher acquirements.

The possession of them or knowledge in drawing, botany, chemistry, and vegetable physiology is not incompatible with a will to labour; and work they certainly must, or all their attainments will be useless. Some of the best gardeners in Britain, or in Europe, are in the position of the individual who boasted in respect to his linguistic power that he could "hold his tongue in seven languages;" but no one can say they would be less competent if they "knew a little Latin," and could "make out the meaning" of French and German catalogues and books. Undoubtedly the possession of languages other than their own gives to the possessors an advantage in the battle of life.

"W. P. R." appeals to me in what on the face of it appears a very hard case in respect to the extortion of premiums from probationary gardeners. Perhaps the best advice I can give to your correspondent is that he send a copy of the Journal of last week and this to the gardener in question, as peradventure he may have something to say that will put a slightly different complexion on the matter. It is never safe to found a charge on something that is "understood," and no opinion worth giving can be expressed without hearing both sides of a case. If such alleged extortion is habitual the "teacher" cannot long remain in obscurity, nor ought he, and it is very certain that no "noble earl" would permit the practice to be continued under the circumstances indicated on page 342, for he would cease to be "noble" if he did so. I will now wait the issue of events.

I HAD almost forgotten to say what I think about a new vegetable that has reached me from Burghley—Chou de Gilbert. Six heads came by post, and I will describe one of them. It was 6 inches long and the same in circumference, just the shape of a turned-in Cos Lettuce with the outer leaves removed. At the base were elongated knobs, like good-size Brussels Sprouts, firm, but not hard, and in dissecting these sprouts a very distinct but very diminutive Cauliflower-like conglomeration of flower buds were packed, a sort of concrete inflorescence closely enveloped in leaves. On the main head being cut longitudinally, a knob was found ensconced in the axil of every leaf, the knobs diminishing in size, as might be expected, as they approached the top of the head, this terminating in an enlarged quasi Cauliflower. I have seen nothing like it. It is quite dissimilar from Chou de Burghley. I see Mr. Abbey describes Chou de Gilbert on page 292 as a Cabbage-Brussels Sprouts. The subject of my examination, was a Broccoli-Brussels Sprout. Perhaps they do not all develop alike. I simply state exactly what I found. When cooked the quality was unexceptionable. After a winter like the last, and with common Turnip-tops 2d. per lb., wetted to "keep them fresh," and possibly make them weigh well, Chou de Gilbert must be regarded as a vegetable of sterling usefulness. At least, that is the verdict of—A THINKER.

### ORCHID LITERATURE.

THE literature of Orchids is extensive but widely scattered through botanical works, and the number of books devoted to the family is not so large as might be imagined. In the following list I have included all I could gain any information about, also giving the titles of the principal works containing coloured plates of Orchids. Many woodcut illustrations have also appeared in the horticultural periodicals, and a great many species have been described by Reichenbach in the *Gardeners' Chronicle*. The chief authority for the genera is Lindley, whose characters are accepted for 114 out of the 334 genera enumerated in Hooker and Bentham's "Genera Plantarum." Whilst Lindley was editor of Edwards' "Botanical Register" many Orchids were figured and described in that work. Bateman's, Lindley's, and Warner's works are magnificent productions, but necessarily very costly.

Aubert du Petit-Thouars.—"Histoire des Orchidées des trois îles d'Afrique." Paris, 1822. 4to.

Baldwin, Henry.—"Orchids of New England." 4to, sixty-two illustrations. United States, America.

### THE ROYAL HORTICULTURAL SOCIETY.

I HAVE read with much interest your article on the position of the Royal Horticultural Society on page 327, and thoroughly endorse your opinion that it must for its life's sake shake itself free from its present condition of bondage. At present it appears to be handicapped by the Exhibition Commissioners, by the fashionable Fellows, and by a preponderance of members of the Council, who nurse their chains and fear to tear themselves away. But as you point out, the real backbone of the Society is, and should be, Fellows who are practical gardeners and lovers of plants; not those who only make use of the Society for an occasional afternoon's amusement. Previous moves of the habitation of the Society seem to have been too pretentious. What seems to be required in London is a home, where should be located the library, committee rooms, and a hall or room large enough to hold the fortnightly meetings, and no doubt such a home might be obtained without incurring a very great outlay; in fact, it should be at a comparatively moderate rent, so that the operations of the Society at Chiswick and in holding provincial shows should not be hampered. If any such programme were carried out I for one should feel it my duty to double my subscription, and no doubt a large number of real plant lovers would do likewise. I fear I have encroached upon your valuable space, but my excuse must be my anxiety to assist in causing other members to act.—F. R. H. S.

### GARDENERS AND PREMIUMS.

A CORRESPONDENT signing himself "W. P. R." at page 342, brings a serious indictment in regard to the above subject against some responsible person in the employ of an earl—presumably the head gardener—and proceeds to cite his case, or rather the young man's case, distinctly specifying it as a "very hard case," and "representative of many others from the same establishment." What a pity it is he is so careful not to mention names, for surely if his "hard case" is but one of "many others from the same establishment," it is time that gardener and that establishment were better known, for the good of young gardeners in particular, else what is the use of "recording" the case? But stop! I am going too fast; perhaps the case is not what it seems, and perhaps the "representative" of "many others" may not be so black as he is painted. Be that as it may, the "case" quoted forcibly reminds me of a few "facts" that have come to my knowledge in regard to a similar "case," and it will serve to give your readers some idea of what the "other side" of "W. P. R.'s" "case" may possibly be.

Some months ago a young man in the south of England, an entire stranger, wrote to me asking if I could help him into a situation, as owing to domestic affairs he could no longer remain at home, where he had been assisting to manage his father's business, and also stating that he had

been foreman a specified length of time in a certain establishment, and that he could have good references from there and elsewhere. Thinking that the man might have to leave home through domestic affliction, I decided to do what I could for him, and wrote to him for his references, but only one was forthcoming. Knowing nothing in the neighbourhood likely to suit this person, I sent on his first letter to me to an old and valued friend—a gardener of undoubted ability and of unquestionable integrity, and respected and appreciated, so far as I know with one exception, by all who know him—who I thought had, or was likely to have, a vacancy. My friend, taking the same view as myself in regard to his letter of application, thought it would be an act of charity to find him employment. He accordingly wrote to the young man, distinctly stating the kind of work he would be required to do, and the terms upon which he could be engaged, one of which was the payment of £5 as a premium for an unspecified length of time, but which, as a fact, covers three years, a premium which no reasonable person will call exorbitant. The young man replied, and in his letter called this £5 “a large sum,” made particular inquiries as to working hours, inquired if he might have flowers when he wanted them to send away, and distinctly stated that he could “stay at home no longer,” because—now mark this—his “father” was “so servile.” My friend replied to this letter in full, administering such a rebuke that would have decided 99 per cent. of ordinary mortals not to engage, but at the same time frankly stating that if he, the young man, went, and did his duty by him, the gardener, he, the gardener, would do his duty to him.

In due time the man entered upon his duties, and was found to be incapable of performing satisfactorily the work that he was engaged to do; he was then set to do other work, and ultimately sent to another part of the estate. I am informed that he wore gloves when stoking, wore a ring on his finger when at work, and in many ways demonstrated that he was altogether too big for his situation, and attracted the attention of the noble owner of the estate so much by his dress and manners in general as to cause him to exclaim to his lady and the head gardener, who was attending them, that “Young gardeners appear to be getting up in the world.” It is also stated that he would not “turn out” at the same time as the other men, coolly ignoring the foreman’s authority. The effect this sort of thing has upon discipline amongst a large staff of men many head gardeners and others well know. Ultimately he received notice to leave, but was allowed to stay on some time, in order that he might suit himself with another situation. As time passed on and he did not go, my friend had no alternative but to dismiss him with the usual notice.

During the time the young man was there, which was several months, I believe the head gardener deducted about 24s. from his wages—the custom in that establishment being for the £5 to be paid during the first year, the second and third years to be free—about a due proportion of the premium to be paid. From the time of his dismissal until now he has been a perfect nuisance, by writing bullying and threatening letters (all of which I have seen) demanding a return of all or part of the money deducted as a premium, and compensation for dismissal, under pains of exposure in the Press and a letter of complaint to “her ladyship,” under all of which the “victim” bears up most cheerfully. So far as I know the matter is not settled yet, but if the young man thinks he has a “case” he knows the remedy.

Similar instances to the foregoing do arise sometimes, but I am thankful to be able to say, to the credit of young gardeners and the comfort of head gardeners, they are few and far between. Like “W. P. R.,” I will not now either defend or condemn the system of premiums, but content myself by citing a case showing up the other side.—OBSERVER.

#### MR. GEO. MOUNT’S NURSERY, CANTERBURY.

It will be remembered that some years ago I was enabled to record the wonderful success that Mr. George Mount had obtained from a small number of Rose trees which he grew at his small garden at Harbledown, near Canterbury. He was then an amateur in the true sense of the word, loving his Roses and tending them carefully himself, and doing all the work connected with them. This “harmonious Blacksmith,” as we are wont to call him, for he was a son of Vulcan, and also organist, has no small amount of energy, although bad health, which would weigh down many, has not crippled his exertions or damped his ambition. His achievements in that year (1882) in which, after exhibiting, from about 400 trees, twenty-eight times, he gained twenty-seven prizes and a silver cup, of which nineteen were firsts, seemed to have added a fresh stimulant to his zeal, and finding that he could not with any safety go on as an amateur, he determined to try what he could do as a nurseryman. He therefore rented a piece of ground at St. Dunstan’s, on the outskirts of Canterbury, and set to work with his accustomed vigour. Having both a carpenter’s and a blacksmith’s business, he was enabled to put up his houses at a comparatively small cost, or, at any rate, much more cheaply than he could have otherwise done, and as with most persons who commence the putting up of glass, he is constantly increasing his houses.

I may say that his object has not been so much the growing of plants for sale, as that of growing them for cut blooms, and hence his houses are mainly filled with Tea and Noisette Roses, and predominant amongst them that ever acceptable Rose, *Maréchal Niel*. Like the caissons in the charge of the Light Brigade, it is to be found everywhere—on the back and in the front of the houses, enjoying the protection and warmth of the glass, on walls facing east and walls facing west, on standards, and on dwarfs in the open. At this time of the year of course there was nothing

to be seen outside, but I have never seen a more healthy and vigorous lot of plants than those which were rapidly coming into bloom under glass. There is an idea entertained by some that strains have something to do with the blooming character, and a strain known about here as Mrs. Cooper has been considered a very vigorous and floriferous one. Nothing could be finer at any rate than the foliage, or more abundant than the blooms, which hang in thick clusters on the plants trained on the front of one of these houses. The more forward blooms were being sent up to London, while large numbers were rapidly pushing their way. The price which they bring is not so remunerative as it used to be, for while the demand is as great as ever, the supply has largely increased, and the depression in trade, which affects everything, affects even blooms of *Maréchal Niel*.

There is in the first house which Mr. Mount put up a fine lot of other Tea Roses, Jean Ducher, Marie Van Houtte, *Etoile de Lyon*, *Souvenir d’Elise*, &c., &c., which are grown for the same purpose. Another house has just been planted with the same, while out of doors a border has been covered with framework on which lights are placed, protecting them from the frost. These lights are now taken off, and the Roses will come in as intermediate between those planted in the house and those quite in the open. These, too, are vigorous; some have been cut by the frost, but not so much so as I should have expected, while Mr. Mount told me that in his sheltered garden at Harbledown they had been very much cut, owing perhaps to the nearness of water, but the effect of severe winters on Roses is a complex question, which may some day form the subject of a symposium for the “Year Book.” Altogether, I think Mr. Mount’s Rose garden, which is on capital loam, promises to be a success. He has had two very trying years since he began his work at St. Dunstan’s, the extreme drought, especially in such soil as his, having sorely tried his plants.

Mr. Mount does not intend to confine himself exclusively to Roses, although they form the great *pièce de résistance*. He has numerous beds of Hellebores, which are to be utilised for the same purpose. A city so abounding in smoke is likely to require a good many of these lovely white flowers at Christmas time, and they will doubtless find a ready sale. He is also going in largely for Narcissus for the same purpose. The same cause has led him to enter largely into the growth of Chrysanthemums, especially the late-flowering white kinds, such as *Duchess of Teck*, *Ethel*, &c., and a large number of young promising plants showed that he is determined in this, as in other things, not to be behindhand.

Although there is nothing very remarkable about this nursery, yet I have thought that many who know our energetic friend will be glad to hear that he is in a fair way of carrying out, as a grower for sale, the success he achieved as an amateur, and I shall be much surprised if we do hear of him again in the exhibition of his favourite flower, for although he is not likely to measure himself with the giants of the Rose world, I yet think that he will take a fair place amongst those who aspire to make some mark, and that, especially in Teas, we shall see in the future proofs of his skill, intelligence, and industry.—D., *Deal*.

As will be seen from a notice in our advertisement columns, Mr. B. S. Williams, Victoria and Paradise Nurseries, has provided an EXHIBITION OF ORCHIDS AT UPPER HOLLOWAY, which will be shortly opened, and continue open until the end of June. The house employed for the purpose is a spacious structure, 100 feet long and 22 feet wide, and those who saw the beautiful display provided last year will have some idea of what to expect this season, and which will attract a great number of visitors.

— WE have received an extremely large spathe of *ANTHURIUM ANDREANUM* from a plant grown by Mr. Cowling, gardener to R. Ruston, Esq., M.P., Monk’s Manor, Lincoln. It is 8 inches broad across the upper part and 8½ inches deep, very bright in colour, but with a greenish tinge round the upper margin.

— THE Committee of the CANTERBURY ROSE SOCIETY have decided to alter the date of their Exhibition from Thursday, July 1st, to Tuesday, June 29th, in order to avoid clashing with Reigate.

— “D., *Deal*,” writes:—“I have to thank ‘T. W. G.’ for noticing my slip of the pen with regard to ROSE SUNSET. May I also notice an hiatus in my paper on “Auriculas at South Kensington,” whether my fault or not I cannot say. After “it seems impossible” there should have been added, “to get these bright violet-purple tints of body colour with an orange or yellow tube.”

— “LANARKSHIRE BEE-KEEPER” writes:—“In the remarks by

"W. J." on the late Mr. ANDREW TURNBULL of Bothwell Castle Gardens, he says, 'It is generally known that Mr. Turnbull raised more fine seedling Heaths than any man, and that of these plants he was a most successful cultivator.' It may not be uninteresting to many of your readers to know what Mr. Turnbull said to me when speaking on the subject of crossing and hybridising, as follows:—'Notwithstanding all the time spent in cross-fertilising and hybridising, all his best seedlings without exception were haphazard seedlings,' finishing his sentence with one of his hearty laughs, so characteristic of that gentleman, with whom I had been on intimate terms for more than forty years."

— WE are informed that the BROCKHAM ROSE ASSOCIATION have accepted the invitation of Wildman Catley, Esq., of Oakdene, to hold their show at The Holmwood, near Dorking (station L. B. & S. C.) on Saturday, July 3rd, 1886.

— MR. R. BEGBIE, The Gardens, Ravensbury, Ascot, Berks, writes as follows regarding THE WEATHER:—"Temperature this morning (May 1st) 15° of frost registered by Negretti and Zambra's thermometers. Gooseberries and Pears injured greatly; also Rhubarb, Strawberries, and tender growths generally." In several districts around London from 6° to 8° of frost were registered on the same morning, and it is to be feared that the fruit blossom has suffered seriously. Numbers of Pear flowers we have examined are black in the centre, though apparently uninjured externally.

— GARDENING APPOINTMENT.—Mr. Angus MacLeod, late foreman at Wemyss Castle, Fifeshire, has been appointed gardener to the Marquis of Headfort, Headfort House, Kells, Co. Meath.

— THE LEEDS PAXTON SOCIETY held its second ordinary meeting on Saturday, 17th ult. (Chairman, Mr. W. Smith, gardener to W. Green, Esq., Roundhay), when a paper was read by Mr. J. Franklin, gardener to J. Barron, Esq., late M.P. for the borough, "On the Habit and Treatment of the *Calanthes*." Mr. Franklin being a known successful grower there was a large attendance. After many questions had been asked and answered, a vote of thanks, proposed by Mr. W. Crossley and seconded by Mr. Stewart, and unanimously carried, closed the meeting. The Society has been established to promote superior culture, the exhibition of horticultural products at its meetings, and the reading of essays and discussions thereon by the members. It merits support and success.

— MESSRS. W. RICHARDSON & Co., Darlington, have been awarded a silver medal by the Society of Architects for a PATENT SYSTEM OF VENTILATION TO HORTICULTURAL HOUSES at the Architectural and Building Trades Exhibition, London.

— THE BEDS OF BULBS IN THE LONDON PARKS are now at their best, and although the plants made such slow progress at first, they have proved much better than seemed likely to be the case a few weeks ago. In Hyde Park, St. James's Park, and Regent's Park the beds are bright, but the most effective we have seen are those in the Royal Gardens, Kew. Near the Wood Museum is a circle, the centre occupied with Tulip Keizerskroon, extremely fine, margined with three lines of the fine white Hyacinth Baroress Van Tuyll and the purple Crocus David Rizzio, which, however, is now out of flower. Near the greenhouse (No. 4) are four beds, two at opposite corners being planted with Tulips, Artus (scarlet) and White Pottebakker in the centre alternately, edged with Yellow Prince and Standard Royal (white feathered crimson). The two opposite beds are filled with Hyacinths, the dark blue Baron Van Tuyll and the white Baroress Van Tuyll alternately in one bed, and Robert Steiger (red) and Alba superbissima (white) in the other. These have a capital appearance, the alternation of colour being much more effective than masses of one variety. There are also several good beds near the Palm house, and we have never seen the greenhouse better filled or more attractive than it is at present.

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for APRIL, 1886:—Mean temperature of the month, 44.5°; maximum on the 27th, 66.7°; minimum on the 30th, 27.0°. Maximum in the sun on the 25th, 123.1°; minimum on the grass on the 12th, 19.8°. Warmest day, the 2nd; mean temperature, 50.6°. Coldest day the 10th, 36.7°. Mean temperature of air at 9 A.M., 44.9°. Mean temperature of soil 1 foot deep, 45.2°. Nights below 32° in shade, six; on grass, eighteen. Total duration of sunshine in month, 124 hours, or thirty per cent. of possible duration. We had five sunless days. Total rainfall, 1.66 inch.

Maximum fall in twenty-four hours on the 2nd. Rain fell on sixteen days. Average velocity of wind 13.1 miles per hour. Velocity exceeded 400 miles on eight days, and fell short of 100 miles on one day. A cold month, with average rainfall and sunshine. Heavy gales in the first week with mild and rather wet weather; the rest of the month cold, the last ten days being dry and the nights in the last week frosty. Vegetation still very backward. Fruit blossom very plentiful, and so far not hurt by the frosts.

— ONE of the finest displays of Tulips we have seen is in the garden of J. S. MORGAN, ESQ., DOVER HOUSE, ROEHAMPTON. The whole of the large beds in the flower garden were planted by Messrs. James Veitch & Sons, and the many thousands of fine blooms in rich and chaste colours produce a magnificent effect. Mr. Forbes, the gardener, has also planted double rows of Tulips round the margin of the Rhododendron beds and shrubbery borders, where the colours are displayed to great advantage by the background of evergreens. Mr. Morgan's garden is remarkable for its high keeping, ample means being afforded for all requirements, and these being supplied by a skilful gardener, everything is in a most satisfactory state. Fruit is extensively grown in many structures, some model three-quarter span houses and a very long fruit case having recently been completed by Messrs. J. Weeks & Co. It is gratifying to observe the excellent manner in which the wall trees are trained. They remind of the trees of the past that were ornaments in many gardens. Such trees occupy no more time in affixing to the walls than when branches are secured in all their crooked deformity, and trees well trained yield as much fruit as those of a contrary character. The Plums and Cherries on the walls in the garden in question are pictures of beauty, and the Peaches and Nectarines under glass are studded with swelling fruit. Vines give promise of heavy crops, and great provision is made for Tomatoes that are required in large quantities throughout the season. Among flowers some grand blooms of Souvenir de Malmaison Carnations command admiration, and thousands of plants of the leading varieties are grown in beds. Chrysanthemums, too, are extensively grown, all the best varieties being included and cultivated well.

— THE title "QUEEN OF THE ORCHIDACEOUS PLANTS" has been bestowed upon *Grammatophyllum speciosum* by some writers, and the *Tropical Agriculturist* thus refers to a fine specimen of this Orchid:—"At the Government botanical gardens at Buitenzorg there is now flowering an Orchid of gigantic size bearing the name *Grammatophyllum speciosum*, and displaying no less than twenty-eight flower stalks. Each of them is on the average 8 feet long. On one stalk alone there are seventy flowers, of which fifty were all open together at one time. The flower is generally 5½ inches in diameter. Each flower leaf is 2¾ inches long and 1½ broad. The colour of the flowers is yellow flecked with brown spots, while the curled edge which, taking the size of the flowers into account, is particularly small, shows more of a copper colour with brown stripes. The flower stalks which, be it noted, are stiff, mostly stand upright, but the numerous heavy leafstalks hang down, some of them being at least 10 feet long. The flowers, like those of most Orchids, remain long fresh. This plant grows on a tree about 8 feet above ground, and has completely encircled its trunk. One peculiarity in its mode of growth is that the numerous roots all grow upwards slantingly. These roots, owing to their great number, form a kind of parasol turned upside down. The leaves falling from above remain hanging between these roots and decay, doubtless serving then as food for the plant. The latter requires, so to speak, very little care. The only looking-after called for is indeed now and then to cut off decayed leaves or flower stalks. Even in the driest seasons it has never any need of water. *Grammatophyllum speciosum* grows in the jungles of West Java. It is the only one of the species to be found throughout the whole island."

#### HEDGES.

ALLOW me to thank your correspondent, "Baillif and Gardener," for his practical remarks on this subject in this week's Journal. I had been treating some hedges in the manner described, and, seeing the improvement effected, was about to operate on others in the same manner, when I wrote the notes referred to. My object in so doing—though I may have failed to make it quite clear—was to point out that there are many hedges not very satisfactory that may be made much better without cutting down, for in some positions a slashed hedge is not very ornamental for some time afterwards. Where there are no serious gaps to fill up, I am quite satisfied, from my own observation, that a thin-bottomed hedge may be made a very good one by sideing it up in the manner described. On the farm where a fence is more the object than ornament or shelter, there is no doubt the process described by your correspondent is the best. As to

the cutting of young hedges, looking at it from a gardener's point of view, I think they can be very well grown, and be more ornamental, when cut annually, say at the end of eight years, than if laid at the end of six years. But I admit it may not be so strong a fence.—R. INGLIS.

### ROSE SHOW FIXTURES, 1886.

For the guidance of those Societies which have not as yet fixed the dates of their exhibitions I append the following list of Rose Shows arranged to be held during the coming season by the National Rose Society and Societies affiliated with it.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Diss Horticultural Society, at Diss, and the Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Farniham Rose and Horticultural Society, at Farniham, Wednesday, June 30th.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Brockham Rose Association, at Dorking, Saturday, July 3rd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Friday, July 9th.

Maidstone Rose Club, at Maidstone, Friday, July 9th.

Cray Valley and Sidcup Horticultural Society, at Froggnal, Saturday, July 10th.

Wirral Rose Society, at Birkenhead, Saturday, July 10th.

East Gloucestershire Rose Society, at Moreton-in-Marsh, Tuesday, July 13th.

National Rose Society, at Birmingham, Thursday, July 15th.

West of Scotland Rosarians' Society, at Helensburgh, Friday, July 16th.

The only fixtures of Rose Shows not in connection with the National Rose Society that have as yet reached me are the two following:—

Oxford Rose Show, Wednesday, July 7th.

Crystal Palace Rose Show, Saturday, July 3rd.

### GLOIRE DE DIJON ROSE.

It is questionable if any Rose possesses a better constitution or flowers with greater freedom than this. For size and fragrance its blooms early in the season are unsurpassed, and very few Roses open their flowers so freely during the dull days of winter and spring. With this Rose alone there need be no difficulty in maintaining a continuous supply of blooms from the end of January until they can be gathered outside. They can be had earlier, for this year we were cutting from it at Christmas. In a cold house it comes into flower early in May—if in a southern aspect earlier—and can be succeeded by plants on a sunny wall outside. In this position they commence growing early, and are often destroyed by late frosts unless slight protection is afforded them. They are worthy of this; a little old tiffany is ample for shielding their tender buds and foliage from cold winds and frost.

For very early flowering plants that have been forced early this season are decidedly the best. Ours for this purpose are trained under the roof of the Rose house, and are in 10-inch pots. They have been flowering since Christmas, and have still several buds upon them. They will presently be transferred into 12-inch pots without disturbing the old ball very much; in fact, the drainage and loose soil from the top of the ball only will be removed. They will not be severely pruned, but thinned to induce the formation of new shoots of moderate strength, for these thoroughly ripened are preferable for early forcing. These plants will in all probability be grown under glass the whole of the season if the space they occupy is not required for others. If so, they will be turned out and secured to a south wall or some warm sunny position to ripen and harden their wood. We top-dressed the soil towards the end of October, and then start them gently into growth. They can either be trained when brought indoors under the roof or round fine stakes inserted near the sides of the pots. No pruning at that season is attempted, and no feeding is practised after the plants are placed outside, the object being to ripen the growth thoroughly and not to encourage its extension.

Small plants that were rooted in autumn in 3 to 6-inch pots will flower about the end of January or early the following month. If these have been wintered in a cold house, such as a vinery or Peach house, their roots will be active, and signs of growth will be visible. These should be repotted, giving them a shift 2 inches larger than those they are now growing in. Place them at once in a temperature of 50° to 55° at night, the latter during mild weather only. No air should be admitted until the weather is sufficiently genial in spring to avoid chilling the plants, which would be certain to produce mildew. About the beginning of June

the plants may safely be grown on without the aid of artificial heat. It will be seen soon after the plants have commenced activity that one or more fairly strong shoots will issue from the base. When these are 1 foot or 18 inches long, the remaining portion of the plant may be removed, and one or two encouraged to extend upright. Care must be taken not to destroy the points of these shoots, or lateral growths will be formed. When the plants are from 3 to 4 feet in length they may be placed into 10-inch pots, which will be large enough for plants with stems 14 to 16 feet in length with several strong lateral growths upon them, for this variety, unlike *Maréchal Niel*, will branch towards the top. As growth extends they should be trained under the roof of the greenhouse or any other structure where they will be exposed to light and sunshine. Those for early forcing should be kept under glass until the end of August, when they may be turned out to harden, or they may be left under glass until the middle of September, when they can be trained round stakes and placed outside exposed to one or two early frosts. When these Roses are subjected to frost they enjoy a complete rest afterwards, and when excited in heat start freely and vigorously. If left outside, these plants will be in capital condition for housing towards the end of November, and if started gently into growth will unfold their flowers towards the end of January or early the following month. Roses brought forward gradually to flower towards the end of March and during April will possess fine foliage, and for this purpose some of them may be trained to a few stakes so as to form even bushes when they flower. Plants trained after this manner are very effective with from two to three dozen fine flowers upon them and the whole of the stakes hidden from view by the foliage. For purposes of decoration this mode of training is decidedly the best, but when the blooms are grown only for cutting the plants are just as well trained round four or five stakes. If plenty of these plants are grown, they can be retarded by keeping them in a cold house or frame and introducing them into heat as required to form a succession until they can be had outside.

As these cease flowering it must be decided whether they are to be retained instead of those that have been forced early in 12-inch pots; if not, they can be cut close back and allowed to start in a cool house, to be finally planted outside or conveyed to the rubbish heap. Young plants can be grown on so easily that we do not care to retain them for indoor purposes after they have been flowered in the size pots mentioned. Other plants started later, even while flowering, often produce strong shoots from the base; and when this is the case they may be pruned close back and trained under the roof for early flowering the following year. After these have fairly started into growth they may be transferred into 12-inch pots, and after flowering can be retained for outdoor planting or be conveyed to the rubbish heap.

Many may not be so fortunate as to have plants in the condition indicated, but some splendid plants may be raised for flowering early next spring from cuttings inserted at once. Cuttings of young wood, not half ripe, root freely at this season if inserted together in 5 and 6-inch pots, shaded from the sun and kept air-tight until rooted, which will take place in about three weeks. Two joints of wood will be sufficient for the cutting, and the top eye only should be left above the soil. After insertion give a good watering, and cover the pots with bellglasses or a handlight. We generally employ the latter, and place it in a temperature of 60° to 65° by night. If kept air-tight the cuttings will not damp, and they will not need a farther application of water until rooted. When they reach this stage they must be gradually hardened to light and air until they bear full exposure in the house in which they are rooted. As soon as they are hardened place them singly into 3-inch pots and grow on for a time in the same temperature. By the time they are 1 foot high they should be in 6-inch pots, and from these when full of roots be transferred to 10-inch pots—the size they are to flower in. By the time they have filled the second-sized pots with roots they can be grown on with the remainder of the stock without the aid of artificial heat. These plants should be grown under glass the whole of the season, for it will be late before they have ripened their growth sufficiently to flower well. Towards the end of October they may be trained round stakes and stood outside until frost compels them to be taken in. Where earlier plants are grown these should not be brought into flower until the spring has well advanced; if they can come on under cool conditions they will flower all the better. They can easily be retarded by keeping them in cold frames.

This Rose succeeds admirably in a compost of rich fibry loam of a moderately light nature, to which may be added one 6-inch potful of bonemeal and the same quantity of soot to each barrowful of loam. If the loam used is heavy a few quarter-inch bones and nearly one-third of leaf mould may be used with the addition of coarse sand. If the loam is rich we prefer using it without adding manure to the compost, which may result in a little stronger growth, but it will not be so firm as when grown in the compost previously named. The object is to obtain firm well-ripened growth, and not pithy wood that is liable to die in winter or fall just when the flower buds are half swelled. When plants are raised from cuttings a little leaf mould, say one-third, may with advantage be added to the compost to encourage rapid growth. In the compost for these plants transferred from 10 to 12-inch pots about one-seventh of decayed manure may be used.

When potting these plants, clean well-drained pots should be employed. The old balls should not be disturbed further than the removal of the drainage and loose soil about the surface. Take care that the plants do not become root-bound before they are transferred into larger pots. The soil should be pressed firmly into the pots, as this insures sturdy growth and saves labour in watering.

To grow this variety or any other Rose to perfection they should never

suffer from an insufficient supply of water at their roots. Not even during the resting period should the soil become dust dry. During that period it must be kept in an intermediate state as nearly as possible. Apply water carefully after the plants are first potted until they are rooting freely in the new soil, when liberal applications may be given. No feeding will be needed until the plants have filled their pots with roots, when they may be watered every time they need supplies with liquid manure in a weak state. In preference to feeding with liquid we apply a little artificial manure to the surface of the soil once a fortnight, and give clear water only. This is continued until growth is completed, and then discontinued until activity commences again during forcing operations. We have invariably found that the roots do not work actively near the surface of the soil when liquid is applied, it appears to sour the surface soil; but when artificial manure is applied the roots work very freely on the surface.

These plants should be kept free from insects, which will be the case if the plants are syringed with a weak solution of softsoap, and water once or twice daily according to the state of the weather. Aphides are best destroyed by lightly fumigating the house in which they are growing with tobacco smoke. Two or three applications are much safer and better than one very strong fumigation. Mildew will not appear if the plants are properly treated and a free vigorous growth maintained from the first. Cold draughts or a check from any cause will result in an attack of mildew. When the plants are attacked nothing is better or destroys it more quickly than 1 oz. of soft soap dissolved in a gallon of water into which one good handful of sulphur has been stirred. The plants should be well syringed with this solution, which should be left upon them for two or three days, and then syringed off with clean tepid water. Sulphide of potassium has been strongly recommended as a remedy for mildew, but those who have not used it should do so carefully, for it will discolour white paint—it turns it the colour of rusty iron. As soon as we discovered this we placed it on one side to be tried on plants out of doors.

Such varieties as Maréchal Niel, Rêve d'Or, Larmarque, Cheshunt Hybrid, Reine Marie Henriette, Belle Lyonnaise, William Allen Richardson, a pretty free Rose and well worth growing, will do well on the same principles of culture as advised for Gloire de Dijon. With the exception of the first mentioned none is so free, and even it does not bear the same forcing as Gloire de Dijon. The fourth and fifth are worth growing and forcing for their colour.—WM. BARDNEY.

### HORTICULTURAL SHOWS.

THE following are the dates of the principal Shows to be held during May and June this year. The Rose Shows are given in another column. The great event of the season will no doubt be the provincial Show of the Royal Horticultural Society at Liverpool at the end of June.

#### MAY.

11th.—Royal Horticultural Society, South Kensington, Committee meetings and Promenade Show.

12th and 13th.—Birmingham Exhibition of Orchids in the Botanic Gardens.

19th.—Royal Botanic Society, Regent's Park, Summer Show.

21st and 22nd.—Crystal Palace, Summer Show.

25th.—Royal Horticultural Society Committee meetings and Exhibition of Pot Roses, Azaleas, &c.

#### JUNE.

8th.—Royal Horticultural Society Committee meetings; Orchid Exhibition.

9th.—Royal Botanic Society second Summer Show.

11th to 18th.—Manchester National Horticultural Exhibition, Old Trafford.

22nd.—Royal Horticultural Society Committee meetings and Pelargonium Show.

23rd and 25th.—York Floral Fête.

29th to July 5th.—Royal Horticultural Society Provincial Show at Liverpool.

30th.—Croydon Horticultural Show.

30th.—Royal Botanic Society's Evening Fête.

### PLANTS FOR SHRUBBERY AND WOODLAND BORDERS.

(Continued from page 319.)

DELPHINIUMS are stately, and their metallic blue flowers very beautiful—most blue of varied shade. They like open spots, but need shelter against winds, which shrubs afford perfectly. The finest of all is perhaps the Gloxinia of the woods—the Foxgloves—spotted Digitalis. Seed sown about this time, the plants pricked off and otherwise attended to, will be strong by autumn and fit to plant anywhere, doing well in any soil; but they flower longer in poor than in rich soil. They need open spaces, but with shelter near. They seed freely, and make grand masses. Honesty, though a biennial, when once established maintains its own. Its seeds being scattered naturally give rise to a numerous progeny, and very effective they are in early summer. Seed sown in spring will give plants fit to put out in autumn. The variegated form is attractive. Charming as Wood Anemones

are, they improve immensely by having as associates the varieties of *A. coronaria* and *A. fulgens*. Sow a bed now, and transplant them in autumn. *Oxalis rosea* is simply as hardy as Wood Sorrel, and does well enough in well-drained soil in woods, and it comes freely enough from seed sown in a frame, the plants being grown on outdoors and put out in autumn. Autumn is the time to plant, for when left until spring the plants hardly get hold before summer is upon them, and they get dried up. In order to give the plants a start clear away the coarse weeds, break the ground thoroughly for the stronger-growing kinds, and keep them from being overpowered and smothered in the year after planting, and once they get firmly established they give no further trouble, only coarse weeds ought never to be allowed to predominate.

In planting just look around, and as the Primroses appear naturally so strive to put out the nurselings. Irregular-shaped masses as far from the circles and ovals, triangles and diamonds as possible. There are many places in shrubberies and woods that are suited to plants of a higher class. I was particularly struck the other day with fine masses of *Lilium candidum* that in front of sheltered bushes had taken to themselves forms on the grass in what had no doubt been a bed on a lawn some time. They were only in strong leaf of course, but it was not difficult to portray the effect of such masses in early summer with a background of evergreens. *L. tigrinum* does well in such positions; *L. croceum*, *L. davuricum* (umbellatum) vars., *L. chalcedonicum*, *L. Martagon* vars., and *L. superbum* vars. all succeed admirably, being planted about 4 inches deep in the first instance, and then left alone until they begin to push each other out of the soil, as they will when they become strong, and then is the time to take some of them up and plant elsewhere. *L. auratum* is quite at home in sheltered places. *Gladiolus* of the *blandus*, *byzantinus*, *cardinalis*, *Colvilli*, *communis*, *floribundus*, *insignis*, *psittacinus* vera, and *sagittalis* are quite charming in open sunny positions amongst shrubs where the soil is light, and *G. ramosus* vars. do first-rate in open spaces. All increase rapidly and form effective groups. They should be planted in autumn about 4 inches deep. In places that are not very much shaded we can bring together the Hellebores or Christmas Roses. *H. corsicus* is a fine shrub-like evergreen with deeply serrated tripartite leaves on stems about 2 feet high, and has greenish white flowers in winter and spring. Then there is *H. viridis* in a similar way, with green flowers, and *H. atro-virens*, with *H. antiquorum* and *H. abchasicus albus*, both having greenish white flowers, and the similar *H. olympicus*. For mixing with these we have purples, *H. caucasicus punctatus*, *H. atro-rubens major*, *H. abchasicus metallicus*, *H. colchicus*, and *abchasicus purpureus*. For margining *H. guttatus*, *H. niger* and its vars. *altifolius*, *caucasicus*, and Scotch and Manchester varieties of *H. niger angustifolius*, and besides these there are many garden varieties. These like moist but well-drained soil. If Winter Aconite and Hepaticas are associated with the Hellebores the effect is superb. Trolliuses in variety give their golden globes in early summer, and do well in moderate shade, with soil similar to Hellebores—moist, not wet.

In semi-wild places what is finer than *Anemone japonica* and its white variety? They like protecting company, growing, flowering, and increasing to an amazing extent, and in sheltered spots the flowers are had much later than in the rich soil and open spaces of dressed grounds. Tritomas show finer there than isolated on lawns. The different kinds need never lack suitable positions in a stretch of shrubbery or woodland. They look best when seated on a gentle knoll with Pampas Grass high up in a recess, for whilst some plants tell best at a close view, others show to greatest advantage in the distance.

Open glades give scope for patches of German Irises, and the taller *I. orientalis*, *Hemerocallis*, *Asphodelus*, *Anthericum*, *Funkias*, *Paeonias*, &c., forming effective groups, only avoid formality. *Dictamnus*, that does not like the bare border and constant hoeing of gardens is at home there, and so are the Michaelmas Daisies (*Asters*) set back where they get plenty of sun, with shelter from winds. The perennial Sunflowers spread rapidly if only the soil is loose, and their large flowers on stately stems tell well against a background of sylvan gloom. Specimens—nay, groups—with wildlings scattered about like stray sheep from a flock, of *Acanthus*, *Eryngium*, *Ferula*, and their like, with *Rheums officinale* and *Emodi* where there is a good depth of moist soil and plenty of room both vertical and lateral, such places suiting the gigantic *Polygonum cordatum*, *sachalinense*, and *Sieboldi*, *Veratrum nigrum*, *album*, and *viride*, and *Bocconia cordata*, with *Phytolacca decandra*. Drier places will suit *Heli-anthemums*, *Geraniums* in variety, and *Galega officinalis* and var. *alba*. These and many others can be spared from garden

borders when the plants are divided and replanted, and there are few shrubby borders that could not accommodate the castaways with advantage. Wet spots will suit *Spiræas Ulmaria*, *venusta*, and *Aruncus*, *Astilbe rivularis*, Sweet Flag, *Carex paniculata*, and *Equisetums*, with *Gunnera scabra*. Wet and shady places will suit Ferns, such as *Osmunda regalis*, *Struthiopteris pennsylvanica*, *Athyrium Filix-femina* and its beautiful varieties, *Lastrea dilatata*, &c. If there should be a rivulet, however tiny, and it can be widened so as to form a small lake, then the Bull-rush is useful, *Aponogeton*, and the *Nymphæas*, with other aquatics. We get the moisture-loving plants altogether, and if judiciously placed they form quite a feature.

Plenty of places will present themselves as suitable for single Roses as *Rosa rugosa*, Paul's singles, &c., that are so finely contrasting with the Dog Rose in summer with flower and in autumn with fruit. Sweet Briar will lade the air with fragrance and Rose of Sharon (*Hypericums*) will light up the sombre summer foliage with gold. Bare tree stems with not very vigorous heads, but past their best, can be clothed with Clematises, such as Traveller's Joy and *C. montana*. Roses, too, of the common climbing sort, Ayrshire, Boursault, and evergreen; and if Virginian Creepers, Vines, and Hops are added, something of the picturesque will be obtained, charming in summer and still more so in autumn with the rich tints the foliage imparts to the scene. Honeysuckles will complete the beauty of the scene; they look so natural twining about trees. Bare spots in shade or open are suitable for bulbs. Winter Aconites, Snowdrops, Daffodils, Scillas, and others for shady situations or under deciduous trees; and Crocuses, with the choicer Narcissi, for open places, bulbs of all kinds doing well in grass, being all the better of a lifting occasionally; besides, the bulbs that are used in bedding are utilised annually for planting in shrubby borders and woodlands. The time to lift, divide, and replant bulbs of all sorts is as soon as the foliage dies. Drying is only a matter of convenience with many bulbs, and with some is positively injurious, especially for Snowdrops and Daffodils. What a fine show Tulips make on grass! They only want a trial in good soil in open spots, keeping them from being smothered with rubbish, whilst little attention is needed for most, whether cultivated or semi-wild.—G. ABBEY.

#### AURICULAS AT SOUTH KENSINGTON.

"D., Deal," at page 339, does not place the details of the National Exhibition fairly before the readers of the Journal, and he is quite incorrect in some particulars. The dry statement that Mr. Horner was absent has to be accounted for by his absence from his plants for about a period of three weeks previous to the exhibition watching by the death-bed of his mother. His plants were five days late, had he been at home to attend to them he would undoubtedly have been present as usual. Mr. Brockbank, not "Brocklebank," was not represented; he did not intend to exhibit if his plants had been in. There was not such a very great falling off in exhibitors. I find on reference to the prize list that there are seventeen prizetakers, some of them exhibitors for the first time. I am also considerably bewildered by the remark that Mr. Turner's Auriculas had received fire heat "night and day since Christmas." All I can say is that our Auriculas had no heat, except sufficient at nights to keep out the frost, and they were certainly some days in advance of Mr. Turner's. Further, I must protest against the remark that the trusses of the Auriculas in the large collections had spindly stalks, requiring sticks to support them. "D., Deal," knows quite well that this is a slur on the professional character of an Auricula grower, and as far as I am concerned the statement is utterly untrue. Mr. Castle saw our plants five days previous to the exhibition, with the trusses all standing up firm and elastic, and not a stick to one of them, and as soon as the plants came home the sticks were removed, and although the plants had been two days in the conservatory at South Kensington, and two nights in the close van, the stems were yet as firm and erect as ever, and by the appearance of Mr. Turner's plants I should say his were the same. I have paid some attention to Auriculas during the last dozen years, and am quite safe in saying that "D., Deal's" remarks are neither correct nor generous to the Society. What is one to think of a judge who failed to distinguish much difference between Sapphire (Horner) and Charles J. Perry (Turner)? It is just as reasonable to say there is not much difference between Sim's Eliza and Campbell's Pizarro, or between Lancashire Hero and George Lightbody. In all three cases the difference in foliage and flowers can be distinguished at a glance.—JAS. DOUGLAS.

#### LEEK AURICULA AND SPRING FLOWER EXHIBITION.

The first Exhibition of Auriculas and spring flowers in Leek took place at the Town Hall on May 1st, for the benefit of the Cottage Hospital. The Show was arranged and energetically carried out by a few growers and admirers of the Auricula in Leek, to whom great credit is due. This favourite flower (so little known in Leek) was, of course, the centre of attraction, and considering the lateness of the spring, the specimens exhibited in all classes, more especially the self-coloured edged ones, would compare very

favourably with other exhibitions held in different parts of the country, and augurs well for the culture of this charming flower in this district.

In the green-edged class we missed F. D. Horner and Prince of Greens, these plants not being in bloom with us. Anna (Trail) first honour, L. curgus second honour. Grey-edge class.—The veteran George Lightbody first, Frank Simonite second, Rob Trail third. White-edge.—Acme (Reid) first, Beauty (Trail) second, True Briton third. Self-coloured class was the best class of all, the first honour being deservedly awarded to Negro (Mellor), a splendid trust of eleven pips; Mrs. Heap (Mellor) second, and Lord of Lorne third. Stage Alpines.—Diana first, Lavinia second, Mercury third. Mr. Mellor, nurseryman, Leek, was awarded first-class certificate for a splendid collection of garden varieties Alpines.

The competition for Daffodils (ten varieties) were certainly one of the features of the Exhibition, the blooms being remarkable fine and everything that could be desired. The prizes (which were given by Mr. Mellor, Leek Nurseries) were awarded as under:—H. W. Nixon first, J. Cheetham second, J. Garner third.

The room was suitably decorated with stove and greenhouse plants, kindly lent for the occasion, and Mr. H. W. Nixon of Leek read a very interesting paper in the afternoon and evening upon the history and culture of the Auricula, which he was accorded a hearty vote of thanks.

The Committee are pleased to be able to hand over to the Cottage Hospital a nice little sum.

#### PRIMULA OBCONICA (P. POCULIFORMIS).

SINCE its introduction into this country four years ago by Messrs. Veitch & Sons of Chelsea this species has proved itself a popular favourite with all lovers of Primulas. It is one of those sterling novelties that will not fail to command admiration on account of handsome habit of growth, floriferousness, and pleasing flowers. Moreover, owing to its perpetual-flowering character, it admirably supplies the link wanting in the *sinensis* section—abundance of flowers during the summer. Beautiful as the numerous varieties of the *P. sinensis* section are, their flowers are not (with the exception of the doubles) so suitable for cut purposes as those of *P. obconica*. There is a want of lightness about the blooms of the former that prevents their use to a great extent in strictly artistic floral arrangements; but it is not so in the case of *P. obconica*, for here you have a truss of blooms, not large or "lumpish," but of a more convenient size, light, and graceful, with blooms of a pleasing shade of colour, ranging from mauve to pale lilac and frequently pure white.

To those who have not seen this beautiful species in its true character my description of its good qualities may seem somewhat exaggerated. In order to dispel this illusion I may say that my employer is an accomplished artist, and whose friends possess similar acquirements; these, one and all, are charmed with this species. In consequence of its being such a favourite here I have long ceased to grow any of *P. sinensis*. Here, however, it grows under conditions more favourable to the development of its true character than is usually accorded to this or other plants of a similar character.

Our plants, as soon as they commence flowering, are employed to form portions of several groups of plants which are arranged in a large winter garden here; and as these groups are arranged on large irregular mounds of soil interspersed with large blocks of stones, among which the pots of the various plants used are plunged up to the rim, the Primulas having what is most congenial for their roots, a cool and moist condition unattainable in the ordinary conservatory or greenhouse. Some of these plants are grouped in masses, others placed in clefts between the large boulders of stones, and in this position they thrive remarkably well. As a proof of the good effects of having their roots plunged in a cool moist medium as just described, I may state that although the best of our plants are growing in pots of not larger than 5-inch size, each plant carries on an average from six to fifteen trusses of bloom.

The culture of *P. obconica* is by no means difficult for anyone possessing a greenhouse. Seed should be sown now in pots or pans filled one-third of their depth with drainage, over this place a layer of rough material, filling the remainder of the pot to within an inch of the top with equal proportions of finely sifted peat, leaf mould, loam, and sand, pressing it in firmly and giving when finished a watering with a fine-rose waterpot. On this sow the seed evenly, covering the pot with a square or circle of glass, and plunging it if possible up to the rim in cocoa-nut fibre in slight bottom heat. Cover the glass with a layer of fibre or a sheet of brown paper until the seed commences to germinate, then gradually expose the seedlings to the light, and after a few days place the pot on a shelf as near the glass as possible, taking care to shade the young plants from sunshine. As soon as the plants have formed the second leaves carefully transplant them round the edges of clean 3-inch pots filled with the same compost as before for the seed pots. Water these at once, and plunge the pots in fibre either in a warm moist corner of a greenhouse, or in a frame which can be kept close if desired. In the course of a couple of weeks the young plants will be fit for potting singly in small 60's, using a little decayed cow manure and a sprinkling of old mortar in addition to the compost already mentioned. Replace and plunge the plants in the frame, attending carefully to watering, and shading, and airing, and when the pots are full of roots shift them on into 5-inch pots. In potting for the last time allow the depth of at least an inch from the top of the pot to remain; the object of this is to permit the plants being top-dressed with a little cow manure and Clay's fertiliser after they have borne their first flowers. This species is a very free rooter, hence it requires stimulating frequently during the flowering period. The top-dressing will work wonders in the course of a few days; indeed, we often find the inch of manure top-dressing full of delicate white and pink roots within a week of its application. A little soot and liquid cow

manure is an excellent cooling stimulant for applying bi-weekly to this species when in flower. *P. obconica* will not bear overpotting, therefore do not put the plants in a larger size than 5-inch pots.

Old plants are easily rejuvenated by dividing them at any time during the spring and summer and growing on as advised for those grown from seed. The plants grown from seed will, if the foregoing simple requirements have been attended to, commence to flower by the middle of September, and continue to do so, more or less, all the year round, especially in a cool, moist, and shady position. This species is reputed by some to be hardy enough for growing out of doors, but having tried it for two seasons under similar conditions to *P. cortusoides*, which thrives well with us out of doors, we cannot report favourably of its adaptability for this purpose. Like several other so-called hardy *Primulas*, its proper position is under glass, and when grown under the conditions suggested in the foregoing notes it will prove one of the most beautiful and interesting of the whole family.

*P. obconica* is also known under another name—viz., *poculiformis*,

a bad bargain, but the Company fared better still when Sir Hans Sloane made the ground over to them in perpetuity, on condition that they obtained fifty new plants yearly, until the number of 2000 was reached. As he behaved generously to them in other things, as, for example, contributing towards the expense of their buildings, he well deserved the memorial of a statue in marble, which still remains, though none the better for the action of so many years' moisture and smoke. Any respectable person can obtain from the Apothecaries Company a ticket to visit these Gardens. I regret that so few horticulturists of our time have been within their walls. Perhaps they judge that not much is to be learnt here, yet the place has its historic interest. It is one of the oldest, if not the oldest garden of London. In it were erected some of the first greenhouses devoted to forcing plants or nurturing exotics. At the beginning, species cultivated in the open must have grown nearly as well as they would miles away from London, so pure was the Chelsea atmosphere then. Many trees and shrubs formerly admired and studied have now disappeared, decaying from old age or other causes. A long list of famous men,

Fig. 66.—*PRIMULA OBCONICA* (*P. POCULIFORMIS*).

and as such is figured and described by Sir Joseph Hooker in the "Botanical Magazine."—T. W. SANDERS.

[Our illustration was prepared from a plant in the collection from the Edinburgh Botanic Garden, shown at the *Primula* Conference, South Kensington, on April 20th.]

#### LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 8.

TIME was when we could look from the green fields of Chelsea to the broader fields and hills of Battersea opposite. Battersea has, indeed, yielded most of its market gardens to the ruthless builder, but a green portion of Battersea is preserved intact within its park, where, under judicious treatment, and by careful adaptation of place, so many exotics flourish in the uncertain climate of London. The Chelsea meads, where cows grazed, people drank tea, and botanists hunted for specimens, have gone; houses cover the ground mostly, though the Apothecaries' Garden does yet keep open what was once a field, and in the seventeenth century liable to be overflowed during some tides. When the Apothecaries got this piece of land in 1673, at a rent of £5 per annum, they did not make

gardeners or botanists, might be given, whose feet have oft trodden this small area, for I suppose it is only three acres. Amongst these memory recalls, beside Sir Hans, the genial Evelyn, Sir Joseph Banks, Petiver, Miller, Forsyth, Fraser, Anderson, Fortune, and Curtis. The esteemed Curator at present is Mr. Thos. Moore, F.L.S. He has held the office since the summer of 1848, and I trust he may be spared to reach his jubilee.

Most visitors enter these gardens by a gate in a side lane from Queen's Road that once led down to an old tavern, "The Swan." The effect of the first view, I think, is to give us the idea that the extent is greater than is the fact. The principal houses lie on the right, also the offices, the herbaceous ground to the left, a few trees are scattered over the centre, but there are no shrubberies. A sloping bank on the east side is devoted to Ferns, but at the time of my visit this did not appear to advantage. In a corner close to this stands yet the Oriental Plane of large dimensions. It is, however, dead, having suffered like some others here, during the making of the embankment. Conspicuous near the river is the sole surviving Cedar, which, with its companion that died off some years ago, were familiar landmarks to those passing along the Thames, and which had the honour to figure as frontispiece, with a bit of the Gardens, to a curious and scarce book about physicians, entitled "The Gold-headed Cane." This Cedar was planted in 1683, being then

3 feet high, so that it is certainly above 200 years old, but its size is not remarkable. I have seen larger, which I have reason to think its juniors. Perhaps the growth was checked by some lopping. This, Miller remarks, is injurious to the Cedar, and he attributes the dwarfing of a couple here to much treatment of this sort. Four, it seems, were set originally, and two cut down in 1771. The third was greatly injured by a snowstorm of Jan. 1809, and finally succumbed.

In one part of the ground, when Mr. Moore took the curatorship, were a number of old Apple and Pear trees which bore tolerable crops; but their removal was deemed necessary, nor was it desirable to replace them. (Early in this century a great deal of fruit was produced in Chelsea orchards.) The aged Cork Oaks and the Pistachia tree were not to be found, nor the large Magnolia Faulkner saw; the celebrated Paper Mulberry and the Pomegranate had also gone. Amongst its notable trees was a Maidenhair Tree or Ginkgo (*Salisburia adiantifolia*), an offshoot from the remarkably fine tree once at Mile End nursery, has left but its memory. Of the survivors I might name an old Quercus Ilex, a Service Tree (*Pyrus Sorbus*), a middle-sized Black Mulberry—perhaps descended from Queen Elizabeth's tree, formerly not far off—and a few varieties of the Willow. A specimen of *Syrax officinalis* looked flourishing, though I could hardly believe it was the one mentioned by Loudon in 1838 as flowering and fruiting well every year. On a south wall *Forsythia Fortunei* was coming into bloom, and sundry *Mezerions* scattered about, and there were a few more spring-flowering species, chiefly bulbous. The north-east corner exhibited a quantity of *Yuccas* that seemed very thriving. Rather a pretty effect was given to some beds by edging them with moss. This had, however, suffered from the severe winter. For the instruction of students a number of beds were set out systematically with exotic and indigenous plants, many medicinal, and I suppose at first these were grouped on the old or Linnean system, then in favour; now the natural method is followed. I only add that the first example of *Greya Sutherlandii* known to have flowered in Britain was reared here.

The oblong space between the houses of Sloane Street and Cadogan Place was, at one date, called "Sloane Square," more correctly it is now styled Cadogan Gardens. It is divided into two portions, the northern one being much larger than the other. This large plot of ground has the peculiarity that it lies quite a foot below the level of the land around; some think it was purposely contrived by the horticulturists who first had it in hand, for it was early during this century arranged as a botanic or nursery garden by Messrs. Curtis & Salisbury. An elaborate scheme that was devised was only partly carried out, but one side was arranged with beds containing classified plants, all duly named. After sundry changes, Mr. Tuck, florist, removed here from the King's Road, and until about five years ago it continued to be a nursery. Now it being free to the residents and their children for recreative purposes, flower-culture is not pursued, as it was considered better to keep the ground in the style of a miniature park, so that trees and shrubs are abundant, but the borders have little in them except a few specimens of such generally grown Londoners as Flags, Aaron's Rod, and Saxifrages. Its oldest trees are Elms; two of large size, but much decayed, are in the centre of the garden. There are also numerous Limes of moderate size; the Ash and Horse Chestnut, so common in many London enclosures, have only a few representatives. Along the east side are several aged Hawthorns that have flung their branches about in a weird and fantastic manner, and a Robinia of curious growth, for the trunk has bulged at a short distance from the soil, while the tree was but small apparently, and the girth has increased above this point out of proportion. The plan of the gardens is a central grass plot, from which clumps of shrubs branch off into the avenues of trees extending north and south. Lilacs and Laburnums have been freely introduced, also varieties of the Ornamental Currant, but there are few evergreens. Our old favourite, the Guelder Rose, is here, though looking a sufferer from the long winter and cold spring.

The other division of Cadogan Gardens is less carefully tended; it has even more trees, Elms, Limes, and Poplars, which being in close conjunction. One hedge, formed of Hawthorn and Privet mixed, has a pretty effect in spring, the fresh green of the "Maybush" showing off on the dark foliage of the evergreen, slowly opening its new buds. In one part of this space someone has formed a little grove of Hollies, which have long been unlopped, and present an odd aspect.—J. R. S. C.

#### NATIONAL AURICULA SOCIETY, NORTHERN SECTION.

THE Society's Northern Show was held in the New Town Hall, Manchester, on Tuesday, April 27th. It was, as it was feared it would be, not equal in quality and quantity to the average of a fair year's bloom. Many of the flowers were young, and had not had time to expand enough, and there was a lack of smoothness very unlike the standard of the dark stern north. The flowers of Mr. Potts of Hoole Hall, Chester, were the largest and brightest, and he won the chief honours of the Show. Miss Woodhead's flowers, from the near neighbourhood of Halifax, were the next in readiness and brightness. Mr. Wilson and Mr. Pohlman, who generally show well and strongly from Halifax, were sorely kept back by the lateness of the season, Mr. Wilson completely.

Many collections, including my own, will be standing in bloom well into May, and an unreasonable bloom projected beyond the average time is not easily kept long if a spell of hot weather comes. Auriculas have had a very late start and a very tardy progress this year. All the northern plants are in robust health, it is simply their flowers that have suffered from unkindness of the season at the unkindest moment. The Auricula likes plenty of time to expand its flowers, and it is almost equally an evil if that time be shortened by a forcing temperature of artificial heat or lengthened by an undue absence of spring sunshine and warm winds.

In the prize list of the Northern Show, Arthur Potts, Esq., held the champion position with six dissimilar Auriculas, one at least in each class, with Simonite's Rev. F. D. Horner, green-edged, very bright and bold, but not yet flat; Acme, white-edged, also very bright and bold, and also not yet flat; Lancashire Hero, grey, a very difficult flower this season with us all; Alex. Meiklejohn, grey, young and bold, a sort in which excess of size often makes it look coarse and difficult to tone in amongst its fellows; Mrs. Douglas, violet self, young and bright. Second, Miss Woodhead, with George Lightbody, nowhere to be seen in his pomp in this show; Acme, Prince of Greens, generally seen somewhere at Manchester at his best, which is a superb green edge and black body colour, fair round paste, sometimes dense and brilliant, and always execrable tube, never more than a sap green, and often sap and water, a flower for which one feels supremely sorry. It dies with edge and ground and paste all standing, and if its weak tube did not let it down in both life and property, it would be a rich flower indeed. Miss Woodhead's other plants in sixes were seedlings Black Bess, self dark; Mrs. Dodwell, white-edged, and George Rudd, heavily-mealed grey. They were in their youth and bright. Third, in sixes William Brockbank, Esq., Didsbury, with Rev. F. D. Horner, green; Alex. Meiklejohn, grey; Acme, white; Melton's Reliance, white, a very fine thing, but not able at this show to do justice to itself; R. Headly, grey; and Negro, dark self. Fourth, Mr. E. Pohlman, with Prince of Greens; J. Crossley seedling, green; Acme, G. Lightbody, and Sapphire, and a seedling as self. Fifth, Mr. Councillor Bolton, Warrington, with Prince of Greens, Reliance; Acme, grey-edge seedling; Mrs. Douglas, and seedling self. Sixth, S. Barlow, Esq., with Syke's Complete, grey, seedling green edge, seedling self, Trail's Beauty, white; Headly's New Green, and Violet Ruby, a sweet seedling self of great purity of ground and paste. Seventh, Mr. J. Buckley of Stalybridge with Pizarro, self; G. Lightbody, grey; Mrs. Douglas, self; Lovely Ann, green; Acme, white; Alex. Meiklejohn, grey. In four dissimilar, Arthur Potts, Esq., first with Rev. F. D. Horner, green; A. Meiklejohn, grey; Acme, white, and Mrs. Douglas, self. Second, Mr. R. Lord, Todmorden, with Blackbird, self; Acme, white; G. Lightbody, grey, and a green-edge Richard Gorton that seems a flower of high promise. Third, Miss Woodhead, with Smiling Beauty, white; Prince of Greens; G. Rudd, grey; and Black Bess, self. Fourth, Mr. J. Buckley; fifth, Mr. H. Wilson, Halifax; sixth, Mr. E. Pohlman; seventh, Mr. Bolton.

In the open class for dissimilar pairs both as to variety and class, first, Mr. Wm. Taylor, Middleton, with Prince of Greens and Trail's Beauty. Second, Richard Gorton, Esq., Eccles, with Rev. F. D. Horner and Frank Simonite, white. Third, Clement Roys, Esq., Rochdale, with Conservative, white edge (Douglas); Prince of Greens. Fourth, Mr. G. Gordon with Headly's New Green and Trail's Beauty. Fifth, Mr. R. Heys, Norden; sixth, Mr. E. Shaw of Moston; seventh, Mr. J. Hilton.

In pairs for maiden growers only—that is, for exhibitors who never yet have won the amount of their subscriptions at any one show, first, Mr. G. Gordon. Second, Mr. J. Hilton. Third, Mr. H. W. Nixon, a grower from Leek, where the cultivation of the Auricula is being enthusiastically taken up, and inaugurated by a local show where the competitors nobly consent to strive at first for honours only.

The premier Auricula of the whole Show was a plant of Walker's John Simonite, white edge, with finely balanced pips. For this proud position Geo. Lightbody at his best is always a strong candidate, and has much chance by being universally grown. It will, however, be seen by reference to records that other and younger sorts, of which there are comparatively few specimens yet existent, have held the premiership also—a cheering sign of progress.

In single specimens the awards were:—

**Green-edge.**—Premium, Wm. Brockbank, Esq., with Rev. F. D. Horner. First, Mr. Wm. Taylor with Lovely Ann. Second, Miss Woodhead with Prince of Greens. Third, R. Gorton, Esq., with Lancashire Hero. Fourth, Wm. Brockbank, Esq., with seedling. Fifth, R. Gorton, Esq., with Rev. F. D. Horner. Sixth, A. Potts, Esq., with Talisman. Seventh, S. Barlow, Esq., with New Green. Eighth, Mr. Councillor Bolton with Anna.

**Grey-edge.**—Premium, A. Potts, Esq., with G. Lightbody. First, R. Gorton, Esq., with G. Lightbody; and fourth and fifth, with A. Meiklejohn and Lancashire Hero. Miss Woodhead second and third with Rachel and George Rudd; Mr. W. Taylor sixth with Trail's Beauty. Wm. Brockbank, Esq., seventh and eighth with seedlings.

**White Edges.**—Mr. Wm. Taylor premium with Acme. A. Potts, Esq., first and third with John Simonite and Conservative; Mr. E. Pohlman second with Acme; Miss Woodhead fourth with Smiling Beauty; Mr. E. Shaw, Moston, fifth with Bright Venus; Mr. Bolton sixth and eighth with Snowdrift and Frank Simonite; C. Roys, Esq., seventh with Silvia.

**Selfs.**—Mr. Councillor Bolton premium with Sapphire, and fourth and sixth with Sapphire and Black Bess; S. Barlow, Esq., first with Carbuncle; Mr. Wm. Taylor second and third with Pizarro and Ellen Lancaster; W. Brockbank, Esq., fifth and seventh with Lord Lorne and Cymbeline; Mr. E. Pohlman eighth with Topsy.

#### ALPINE AURICULAS.

In the class for four dissimilar, R. J. Gorton, Esq., was first with Victoria, Miss Taplin, John Leech and Echo; second S. Barlow, Esq., with Diadem, Llewellyn, Dazzle and Unique; Mr. E. Pohlman third with four seedlings; Wm. Brockbank, Esq., fourth with Diadem, Mr. Thompson, Beatrice and Conspicua; Mr. R. Hays fifth with Diadem, Llewellyn and two seedlings. Single Alpines, shaded, and yellow centres.—Mr. J. Buckley premium with Diadem; Mr. E. Shaw first with same; S. Barlow, Esq., second and third with Mrs. Meiklejohn and Llewellyn; Mr. Geo. Geggie, Bury, fourth with Unique; Mr. E. Pohlman fifth with seedling. Alpines, pale centres.—R. Gorton, Esq., premium with Victoria; Mr. E. Pohlman first, third, fourth, and fifth with seedlings; R. Gorton, Esq., second with Goliath.

**POLYANTHUSES.**—Three dissimilar black grounds.—First Mr. J. Hilton, with Lancashire Hero, Cheshire Favourite, and Exile; Mr. William Taylor second with the same; William Brockbank, Esq., third with Blackbird, Cheshire Favourite, and Exile; fourth, Mr. J. Wallden, Sale, with Cheshire Favourite, Exile, and a seedling. Three dissimilar red grounds.—First, Mr. J. Hilton, with Lancer, Prince Regent, and George IV.; second, Mr. William Taylor with the same; third, William Brockbank, Esq., with the same.

Single plants, red grounds.—Mr. J. Hilton premium with George IV., third and sixth with Prince Regent and Sydney Smith; William Brockbank, Esq., first and second with George IV. and Lord Derby (seedling); Mr. William Taylor fourth with Lancer. In black grounds Mr. Walkden, premier and first with Cheshire Favourite; Mr. Hilton second with Exile; William Brockbank, Esq., third and fourth with Beauty of England and Lancashire Hero; Mr. R. Heys fifth with King.

FANCY AURICULAS.—There were two fine collections staged. First prize S. Barlow, Esq.; second, Mr. Councillor Bolton. In fancy Polyanthus only one collection was staged, for which a first prize was awarded to S. Barlow, Esq. Twelve Primroses, dissimilar.—First S. Barlow, Esq.; second Mr. Walkden, with fine plants.

Joseph Broome, Esq., Didsbury, exhibited a large and beautiful collection of stove plants in flower, among which was *Ataccia cristata* with ten spikes. There was also a very large, varied, and admirably arranged group of Alpine plants and Primulas from the Royal Botanic Gardens selected by Mr. B. Findlay.—F. D. HORNER, *Burton-in-Lonsdale*.

### HUGHES'S FIR-TREE OIL SPRAY PUMP.

WITH the object of using the well-known insecticide, Fir-tree oil more quickly and effectively to Roses, fruit trees, and large plants generally than could be effected by the hand-syringe or spray-distributor, the pump represented in fig. 67 has been introduced by the proprietor, Mr. G. G. Hughes. It is easy to work, the outflow from the nozzle not being intermittent with each movement of the handle, but continuous, either in a thin stream or fine spray at the will of the operator, the latter being the most economical method of distributing the insecticide. One person can work the pump and direct the solution with the greatest ease, indeed a lady could work it without fatigue. It is simply held in position by placing the foot on the base of the ring, and with the handle in one hand and the nozzle in the other trees or plants can be ex-

Fig. 67.

peditionously dressed for the destruction of insects. Having tried this spray pump, we are in a position to testify that it answers its purpose well.

### THE HUNTINGDON NURSERIES.

THE old and quaint county town of Huntingdon is famous if for nothing less than being the birthplace of Oliver Cromwell; yet in the environs is also to be found the nursery of Messrs. Wood & Ingram, devoted to the growth of popular classes of flowers, and in some score of houses, such as nurserymen know how to construct economically and utilise so well, I found much that was noteworthy.

Clematises are grown in a large house 84 feet by 20 feet, span-roofed, 10,000 plants being raised annually, some being grown to specimen size. Of the single-flowered varieties the best were Alba Magna, pure white, broad-sepalled flowers; Miss Bateman, white, chocolate anthers; Madame Van Houtte, white, mauve tinted; Henryi, large creamy white, one of the best outdoors; Lady Caroline Neville, French white, mauve bars, very beautiful; and the Jackmanni alba, which is destined to become as great a favourite as this type; Gipsy Queen, dark velvety purple; Louis Van Houtte, bluish purple, six broad petals, very showy and free; Madame Grange, crimson-violet, red centre, beautiful; Purpurea elegans, violet purple, large, fine; Ascotiensis, azure blue, large and fine; Jackmanni, violet-purple, still one of the best, superba being an improvement upon it in size and colour; Fairy Queen, flesh with pink bar, very large and fine; Symeana, lavender, deeper bars; Mrs. Crawshaw, pink, pale bronzy bar, beautiful. Of the doubles, Duchess of Edinburgh, white; Belle of Woking, silver-gray, very fine; Countess of Lovelace, bluish lilac. There is a fine stock of that very fine conservatory winter-flowering climber—the very finest of all the Clematis under glass—viz, *indivisa lobata*, and which ought to have place in every greenhouse. The new hardy white Passion-flower Constance Elliott is grown in quantity; its ivory-white and sweet-scented flowers is sure to render it a general favourite.

Pelargoniums are grown extensively. One house 84 feet by 13 feet contained well grown examples in 5-inch pots for decorative purposes, the foliage deep green, and abundant flowers or trusses showing. The trusses are large, and the flowers large without being coarse, and the colour of the flowers clear. Only the commonest loam is used or road sidings, with Amies, a little bone, and soot. Finer plants cannot possibly be seen anywhere, and they show what a lot of trouble we give ourselves about soil when even the commonest may be utilised. Only the best decorative varieties are grown, amongst which are in Regal or Fringed, Duchess of Bedford, white, carmine spot; Duchess of Edinburgh, similar, but with a lake spot and heavier feather; Digby Grand, blue, dark blotch on upper petals, heavily fringed; Madame Thibaut, white and rosy carmine, maroon blotch, showy; Dr. Masters, crimson, black blotch, same colour on lower petals, and smaller blotch; Volonté Nationale, petals blotched rosy carmine, margined pure white; Volonté Nationale Album, white, promises to be equally good as a white, and finely fringed. In show, French, and spotted varieties, Corsair, carmine, crimson blotch, spots on lower petals, dwarf and fine; Decorator,

rich crimson, maroon blotch on top petals, very fine; Elward Perkins, scarlet, dark blotch, extra truss, very good; Fascination, carmine upper petals, rose lower petals, with white centre; Gold Mine, vermilion, maroon blotch on upper petals, white centre, large and good; John Bright, scarlet, maroon blotch, white centre, very free and fine; Martial, crimson maroon top blotch, fiery edge, fine and free; Lizzie, rosy carmine, crimson blotch on upper petals, carmine on lower, white centre, very free blooming; Mabel, maroon upper petals, lower petals rosy carmine, white centre, very beautiful; Mrs. Beckwith, lake, suffused white, maroon feather on upper petals, fine; Mermeris, red, maroon spots; Mrs. Gladstone, blush, crimson blotch, extra fine; Robert Green, purplish crimson, maroon blotch, effective; Rosetta, purple, maroon spots, very free; Triomphe de St. Maude, light purplish crimson, black blotch, very free blooming; T. A. Dickson, rosy crimson, heavily spotted, very free; Tommy Dodd, blush white, crimson blotch, fine; Venus, white, delicate carmine spots, very free and good; Madame Charles Konig, pure white, of good form and substance, one of the best whites. The only Fancy variety grown is Princess Teck, white, carmine spot, very attractive. There is a seedling of great promise, an advance upon Harry Buck. The flowers are large and of good form and substance, upper petals crimson, carmine shaded, and lighter on edge, deep maroon blotch, very clear, lower petals scarlet and clean (not marked as in Harry Buck), dense compact habit, and very free blooming.

That the bedding-out system is not quite so devoid of life as some represent is evidenced by the many large houses devoted to bedding plants, especially Pelargoniums. Of Tricolors one house contains 11,000 plants. Perhaps the finest of the Golden Tricolors is Masterpiece, fine broad black zone. Mrs. Henry Cox is as free as Mrs. Pollock, its markings being bright and intense, well defined rich crimson zone, bright yellow margin. This is considered the finest of the class and an excellent bedder. Macbeth has a very heavy zone and clear yellow margin, and very effective for bedding. Lady Cullum still holds its own as one of the best bedders, the colours being splendid; E. R. Benyon, maroon and red zone, well defined, capital bedder; Peter Grieve is a vigorous grower, with high colours; Prince of Wales must also be mentioned as intensely brilliant in its colours; Acme, narrow red zone and clear yellow edge, is bolder in leaf than most Tricolors; William Sandy is also very bright and a good grower, similar remarks applying to Victoria Regina, broad gold leaf margin and crimson zone. Florence, with its dark zone fringed crimson, is very effective. Sophia Dumaesque, Lady Cullum, and Mrs. Pollock still hold their own as constitutionally good, Mrs. Pollock being unapproached as an all-round bedder. Mrs. Strong has rich foliage and double scarlet flowers, very attractive.

In Silver Tricolors, Lass o' Gowrie is the best bedder, though Prince Silverwing is freer and less bright in its markings. Mrs. Laing also is good. Of Silver-edged, Chelsea Gem, bright silver edge, doubly rosy pink flowers, dwarf grower, capital edging kind, and one of the best general bedders. Avalanche has white flowers, which are produced freely. Flower of Spring may be named as one of the best bedders, also May Queen and Mrs. Vidler, fine silver edge and scarlet flowers. Viscountess Cranbrook is dwarf, clear white edge, and scarlet flowers; whilst Mrs. J. C. Mappin has white flowers with a pink eye, very attractive. Of Gold-leaved varieties, Crystal Palace Gem is still unsurpassed. Verona, however, is a good addition to this class, with plain gold leaf. Golden Superb is favoured with a zone and has crimson flowers, and considered the best of this section. Golden Brilliantissima has every leaf margined with yellow and white, the remainder pea green, a peculiar combination of variegation, small neat grower, and may prove useful for edging; indeed, it is considered a gem for that purpose.

Hollyhocks are numerous, there being thousands as strong and healthy as could be wished in 4-inch pots, fit for planting out at once. It is pleasing to see this noble flower again rising in favour, there being none grander in their season. Seedlings alone are grown, and very properly, as the named varieties are much more susceptible to the disease or fungus that has made such havoc with the Hollyhock of late years. Verbenas are a feature, dwarf and bushy, some 15,000 in single pots without a trace of mildew, bedding varieties being chiefly grown. The best white is White Queen; best pink, Lady Brooke; best purple, Mrs. Langtry; and best scarlet, General Gordon. Other good bedders are Eclipse, crimson; Blue King, bluish purple; Peacemaker, pink; Miss Nevill, white; and Othello, crimson maroon, suffused purple. Fine varieties for pots are Purity, white; Lady Brooke; Hamlet, orange crimson; Lord Brooke, scarlet, white eye; Striata, striped pink and white, quartering regular; The Fairy Queen, light ground, red centre; Compact, white; Mabel, mauve; Fantastic, salmon pink, striped scarlet; Rev. Dawson Damer, scarlet; Victor Emanuel, mauve, tinted plum, light green eye; and Lustrous, scarlet, white eye.

Lobelias are in fine form; the favourites are Brighton, Swanley Blue, True Blue of the pumila section, Blue King being good. *L. pumila* Ingrami originated here, and it still is far the best variety. Dahlias exist in quantity of all the best Show, Fancy, Bouquet, Single, and Cactus sections. In a small house a seedling Carnation attracted attention, purple self, large, bold, smooth flower, of fine form and great substance, very sweet, and evidently of the tree type. Mango Pepper plants existing in quantity, but as this was the first season of growing it I could glean nothing respecting it. Pentstemons were looking healthy, and they are very useful for effect and cutting in late summer; Bonvardias cut back were pushing fresh growth strongly. Alfred Neuner, Vreelandi, Dazzler, Brilliant, and President Garfield are the favourites. In passing through some of the structures I noted Mesembryanthemum cordifolium and its variegated form so suitable for hot window boxes, where too much care is not given in watering, and that very fine plant for window boxes or brackets, the "Cape Ivy," *Senecio macroglossus*. Of Heliotropes, President Garfield and White Lady were fine. Marguerites seem in request, and *Salvia patens* also, the latter being especially valuable, as we have so few bright blue flowers with stems long enough for cutting. *Gynura aurantiaca*, a *Salvia*-like plant with purple stems, leaf veins, and hairs on the leaves is telling as a table plant when of moderate size, and it may be grown in small pots. Ivy-leaved Pelargoniums are present in quantity, and fine they are for pots, vases, and baskets, whether in or outdoor. Of those noticeable for their flowers are Masterpiece, magenta crimson, fine flowers and trusses, Bridal Wreath being the best white; and for bedding, Holly Wreath, variegated, pink flowers; and L'Elegante, creamy white variegation, both good edging sorts. Of Doubles, Gloire

d'Orleans, reddish-purple; Anna Pfitzer, salmon-rose; and Madame Crousse, blush white shaded rose. Of Chrysanthemums there is a full collection of all the leading varieties, and three houses 40 feet by 10 feet are devoted to Carnations and Picotees, of which the collection contains most of the best old and new varieties. Hydrangea cymocladia has large trusses of blue flowers or bracts, there being no need to supply H. hortensis with iron filings to get blue flower heads now we have this.

Ferns of the decorative character, such as Adiantum cuneatum, gracillimum, Williamsi, palmatum, fine; deflexum, with the pinnae hanging or flaccid; scutum and podophyllum, having pink fronds in their young state; and mundulum; farleyense being grown extensively. The very finely divided Pteris scaberula is much in request for decorative purposes, and similar remarks apply to Davallia bullata. Of the bolder sorts Asplenium bulbiferum, Doodia aspera, and Neottopteris Nidus obtain most favour. That best of Silver Ferns, Gymnogramma peruviana argyrophylla, is fine.

In a large house 66 feet by 25 feet Cobaea scandens variegata in strong plants and number suggests the great value of this as a rapid climber for cool or unheated houses, it covering a large space in a season; and also for verandahs, balconies, running round windows outside, it is most useful, and in some respects invaluable. Part of the roof is covered with Maréchal Niel Rose worked on Rêve d'Or, on which it does better than on the Briar stock, being healthier, and the flowers are much larger, the buds resembling miniature Cabbages. Of Tree Carnations the best were A. Alégatière, scarlet: Duke of Wellington, purple; Zouave, red, fine; Louisa Ashburton, white, fringed, very fragrant; Miss Joliffe, pink; Warrior, scarlet; Worthington Smith, scarlet; La Belle, white; Andalusia, primrose-yellow; Pride of Peushurst, canary yellow, are amongst the best. Greenhouse Rhododendrons in their varied colours and delightful fragrance, with plants in 3 and 4-inch pots of Choisya ternata about a foot high were flowering profusely. A large deep pan contains that charming sweet Hawthorn-scented aquatic Aponogeton distachyon growing beneath the stage, and yet full of flowers and foliage. For growing in deep pans indoors, and tanks outdoors where it has a foot to 18 inches depth of water, it is one of the most desirable of aquatics. A few other notes must be reserved.—G.

(To be continued.)

## THE PRIMULAS.

(Continued from page 318.)

To conclude the notes upon the Primulas which have been published in this Journal during the past few months, a list of the species and principal synonyms is given, with references to the page upon which will be found a note describing their characters or culture. The names in italics are synonyms, those with asterisks prefixed being hybrids.

### SELECT NARCISSI.

THE Narcissi are becoming far more popular than the most sanguine anticipated a few years ago, but it is certainly not the minute fanciful distinctions which are as puzzling to the connoisseur as to the novice that will assist in making them the plants for the masses; on the contrary, the public taste is good as a rule, and requires something attractive, and at the same time reasonably cheap. I need hardly refer to their complete hardiness, but as an instance I will just remark on an exceptional test which came under my own observation during the recent severe frost. The case in point is that of *Narcissus pallidus præcox*, the lovely new Pyrenean Daffodil, which when the last long-continued spell of frost set in was in bud, and numbers of them fully 4 inches high. In this stage they were compelled to remain for upwards of three weeks, during the first of which it thawed rapidly during the day with severe frost each succeeding night, the ground in consequence was in a bad condition about them, and the test exceptionally severe. At the same time they withstood it bravely, and every flower ultimately developed well. *N. monophyllus* had the protection of an old light and a couple of bags, and it flowered equally well.

In my present note I have thought it may be of service at this time, when Daffodil displays are so numerous, to describe briefly some of the best and most distinct contained in this genus of golden flowers, so that any wishing to make a choice selection of them may do so readily. It might be of interest if I take them, or at least the earliest portion of them, in the order in which they flower. In ordinary seasons *N. pallidus præcox* is amongst the earliest, its flowers coming in February abundantly, and a few in the latter part of the previous month, it has proved to be a most valuable early variety, is somewhat variable in form, size and colour, that most generally seen being of a soft sulphur white; it grows 8 inches high with slightly drooping flowers, in some forms the trumpet is rather straight and inclined to the creamy white of *N. cernuus*, while in others it is bold and well reflexed. The next to flower are *cambricus* and *obvalaris*, the latter being the true Tenby Daffodil. The former has flowers with sulphur white perianth segments and yellow trumpet, while in the latter the divisions of the perianth and also the trumpet are of a bright golden yellow. The trumpet is beautifully formed and well recurved at the mouth, always assuming a stiff sturdy habit of growth and invaluable for pots for early flowering for the border or rockery; at about the same time we have *nanus*, *minor*, and *minimus* bursting into flower. These, from their diminutive growth, are specially adapted for the rockery or raised border, hardy, sufficiently showy for pot culture perhaps, but very pleasing and attractive for the purpose named.

Then comes the native Lenten Lily, *N. Pseudo-Narcissus*, beautifully adapted for naturalising in woodlands or on grassy banks and slopes under trees—anywhere, in fact, this seems to thrive, and annually furnish abundant blossom. This is followed by *N. lobularis*, together with the various forms of *spurius*, the best of which are *N. spurius major*, and *N. spurius coronatus*, both bold and showy flowers of rich golden hue. At this time a great number of *Narcissus* and Daffodils are in flower, for in

ordinary seasons these will be in flower from the middle to the end of March. And here I would not omit the large and bold flowers of the common double Daffodil, *N. Talamoni* *plenus*, a good useful flower for naturalising, or for the margin of shrubby borders and beds—in any conspicuous place, in fact, it may be introduced among other plants with good effect, but nowhere in overwhelming quantity to produce a monotony.

Amidst all this golden colour comes the matchless flowers of *N. cernuus*, with the varieties *pulcher* and *N. cernuus plenus*. These are among the most exquisite of the whole race of Daffodils. The typical species is the drooping white Spanish Daffodil, others call it the Nodding White Daffodil; but call it what we may, it is lovely in the extreme. The perianth is silvery white and the same length as the trumpet, which latter on first opening is of a pale primrose hue, which changes to white in the second or third day. This is noticeable in the other forms of this choice Daffodil. It is impossible to overestimate either its value or loveliness, and being of equally easy culture as the commoner flowers of this family it should be grown by all.

While speaking of the delicate grace and beauty of *N. cernuus* I am reminded of another equally chaste and good, this is *N. moschatus* and its variety *N. moschatus albicans*; in the type the divisions of the perianth and also trumpet are white, in the latter the trumpet is somewhat larger and fringed with pale primrose, and in all it is somewhat larger. There is, however, considerable variation in the growth and general strength of home-grown roots as against those collected in a wild state, which much favours the former. Before quite departing from the *moschatus* forms I may remark that it is not so well adapted for pot culture as many, since it will not endure artificial heat nearly so well, even when judiciously applied. It is never better than when allowed to flower in its own way. The lovely princeps, with its giant sulphur trumpet and sulphur white perianth, is a charming flower for any purpose, and one deserving extended culture.

Then if we turn for a moment to glance at the various *N. bicolors*, such as *Empress*, *Horsfieldi*, *Maximus*, also called *grandis*, together with *nobilis* and *minor*, we have a set of the most glorious of all the Daffodils. Of strong and vigorous constitutions, each bulb producing when established three or more of their lovely blossoms, which are unequalled for all floral embellishments. Arranged among other things in epergnes and for table decoration generally their drooping or horizontal cups, as the case may be, are most pleasing; in short they rank among the very finest of the group, and are foremost among the so-called grand trumpeters. Where all are equally good it is useless to particularise; suffice it to say that those named possess the same stately habit of growth, and are all remarkable for the great substance of their flowers. In each case the trumpet is a golden yellow with pure white perianth. Not only do these stand out conspicuous in the genus to which they belong, but they hold a front rank among the most beautiful of hardy spring bulbs.

We have also some very fine forms in *N. Emperor* and *N. rugilobus*, which in point of colour are very near akin, but in point of fact the former is a giant as compared with the latter; it is in reality one of the largest in cultivation. The trumpet is yellow, with pale sulphur segments. The same description will fully recognise *N. rugilobus*, which by the way, flowers fully ten days earlier than the Emperor. In *Narcissus maximus* we have the most lovely of all the single golden Daffodils, and also the largest; the cup is beautifully expanded, while the perianth segments are noticeable for a peculiar though constant twist, constituting a distinguishing character.

Leaving the Trumpet or Ajax section, I will briefly turn to the equally valuable *N. poeticus* and its forms. All these are extremely useful as cut flowers, and where such are in demand should be grown in quantity; those most valuable are *N. poeticus angustifolius*, *N. poeticus poetarum*, and *N. poeticus ornatus*. The first named is earliest to flower, the flowers being pure white with a rose-margined cup; the second named has very large pure white flowers, the cup being margined with crimson; the last named is the most valuable of all, the flowers are beautifully formed, and nearly circular, the segments in nearly all cases overlapping each other, of good endurance in a cut state, and comes in naturally at Easter time when flowers for church decoration are in great request, therefore they are doubly valuable, to which may be added their unrivalled fragrance. There are still other varieties of Poet's Narcissus, as *poeticus plenus* and others, but those above are so much earlier as to merit the greater attention. The last section to which I shall refer is the Peerless Daffodils, *N. incomparabilis* and varieties. These are far too vast in point of numbers, or at least names, and may readily be reduced to a few of the most distinct. Mary Anderson may receive a premier place, it is the single Orange Phoenix, the perianth pure white, and the cup bright orange-scarlet; it attracts attention everywhere, and well deserves extensive cultivation. In combination of colour it is unique, and will no doubt be largely grown in the future. Stella forms another pleasing and good form, as well as an early bloomer, and which is being largely used. The great Sir Watkin is the giant of all, a tremendous leap, as it were, into the future, and which has left all else far behind in so far as size is concerned. *Incomparabilis*, *Glow*, *albidus*, *Leedsii*, are others very good and distinct. The list of names in this section is simply bewildering, and doubly so on tracing a catalogue only to find after all the varietal or complimentary names employed, that the perianth is sulphur, and the cup yellow, varied only now and again by the cup being either large or very fine.

Among the Leedsii varieties *L. amabilis* is worthy of note, the cup being conspicuously long, and primrose colour at first, then changing to white, the perianth also white. There are other good and useful varieties well worthy of culture, but which require careful selection, beside which

we have the three double forms of incomparabilis—viz., Double Sulphur, Phoenix, double Orange Phoenix, and the well known Butter and Eggs variety. All these are useful pot plants and valuable as cut flowers, the Sulphur especially so on account of its large creamy-white flowers, which from established bulbs are of great size and substance; this cannot be too strongly remembered for any purpose where choice cut flowers are needed.

In the foregoing remarks I have only given the leading varieties of each section, all equally good and useful for the garden, the conservatory, the rockery, or for naturalising. It may also be noted that those grown in pots the first season may be planted out in clumps undisturbed, and where they will add beauty in years to come to beds, borders, and shrubberies alike, so that by annually purchasing a few for potting, and after flowering to be transferred to beds and borders outside, a gay spring garden may soon be made, and thus form a goodly collection of these choice spring bulbous plants.—J. H. G.

### ORANGE CULTURE IN FLORIDA.

In a manual entitled "Sunny Florida," published at 30, Fleet Street, and giving a great variety of information concerning this American State, is a chapter upon Orange culture, which we have thought worthy of reproduction. The cultivation of the Orange has become a highly important industry, and so many persons from this country are either already engaged in it or are preparing to do so, that the following remarks cannot fail to be instructive.

Whether an individual buys a grove already planted, or land on which to do his own planting, he needs to know enough to select a location most favourable to success. The Orange has been grown successfully on all classes of land in Florida, from the drained swamp-land to the high, poor, black-jack ridges. Nature planted her groves in the swamps and hammocks because circumstances were there more favourable to her purpose and ability. The forest fires which annually swept over the Pine woods could not reach the young Orange trees planted in the swamps and hammocks. Nor were the cattle, especially in the swamps, so likely to cut down the young trees. In addition to these, Nature provided against frost by first planting under shelter of trees, and, where the frost was most severe, on the south or south-east side of our many beautiful lakes or rivers. Of course, under these circumstances, the Orange had to pay a high premium to the forest trees for their protection. It had to yield up to them the largest amount of the fertility of the soil, and hence never attained the large proportion, graceful form, and fruitfulness of the cultivated tree. These trees also bore sour fruit only.

The Orange is not indigenous to Florida. It was evidently brought to this country by the Spaniards, and at a time prior to the introduction of the Sweet Orange into Europe. When, later, the Sweet Orange was brought to this country, the pollen of the Sweet Orange fertilised the flower of the sour, and in the next generation produced the hybrid "Bitter-sweet," now common in the wild groves.

While Florida soil, of almost any kind, will produce the Orange, there are some soils better adapted to the growth of the Orange than others. A naturally well-drained but moist soil should be chosen in preference to the poorly drained, for two reasons. First, a deeply drained soil will allow the roots of the trees to penetrate the earth more deeply, and hence give to them more feeding surface. Second, where the roots are deeply embedded in the soil they will allow deeper cultivation with the plough instead of the hoe. The roots will not grow beneath a level continuously saturated with water; hence, to cultivate deeply such trees as stand on a poorly drained soil, necessitates the constant cutting of the roots on which the trees depend for life. I have seen many groves damaged and many trees destroyed by deep cultivation of trees planted in deep soils.

The richer the land the more vigorously the Orange tree will grow, and the more abundant will be its fruit. The Orange tree is an abundant feeder, and provided the soil is healthful to the plant it is hard to get it too fertile. Hammock land, or land producing hard wood, is generally more fertile than Pine land, and hence the trees do better, usually, on such land. The hard wood indicates the presence in the soil of more potash, which is consumed largely in the production of the fruit of the Orange. This, however, is soon exhausted after the trees come into full bearing, and needs to be supplied, as it does on the Pine lands from the first, in order to secure the best results. The better kind of Pine land is well adapted to the growth of the Orange, especially when the land is gently rolling, and some Hickory is found mixed with the Pine. Pine with black-jack Oak is a healthful soil, but is usually deficient in humus and nitrogenous fertilisers. These should be furnished with such fertilisers.

A rolling surface, with tall Pines thickly standing upon the land, indicates a fairly fertile soil, and well adapted to Oranges.

\* \* \* \* \*

The next thing that may be considered is suitable transportation, proximity to lines of railroads or to navigable streams. Railroad transportation is cheaper and less damaging to fruit than waggon. Water transportation is better than either. It is well to be in reach of competing lines, for then the producer may be sure of reasonable freight.

Care should be taken to plant groves where they are least likely to be damaged by frost. Much has been said about the frost line in Florida, but the settler will have to go below Cape Sable to find the line where frost never appears in Florida. I have frequently, since I have been in the State, known of its effect upon tender vegetation in every county in the State. In the same latitude, exemption from frost damage depends largely upon the presence of moisture in the atmosphere, and hence upon the presence of bodies of water—the wider the surface of water the better. Where water is at hand, the south or south-east side affords the best protection. Our cold winds are mainly from the north-west. When they come from the north-east and generally from the west, the cold is greatly moderated by the influence of the Gulf Stream. When a cold north-west wind passes over a considerable body of water, it is so saturated with warm vapour arising

from the water as to greatly raise the temperature of the atmosphere and check the damaging effects of the frost.

Many of the largest wild groves were cut down years ago, before the Orange interest started, for planting Cotton and Sugar Cane. But many smaller groves were standing when the writer first came to this State, a little less than twenty years ago. These have since been huddled, and are now yielding sweet fruit.

The rolling lands of our peninsula, especially in the vicinity of lakes, furnish many picturesque and favourable locations for Orange-growing.

The Orange, however, is not so delicate as to need entire protection from frost. I have seen it fruiting in the open air along the southern line of Georgia. It has for a century been grown to some profit on the coast islands of Georgia. It is grown in some parts of Italy where there are occasionally snowfalls, and one variety is grown in Japan, where winter snows are usual.

Several plans are employed for propagating the Orange: planting sour stumps taken from the wild grove, and budding with sweet varieties; planting sweet unbudded stock; planting sweet stock budded with special varieties; and planting sour stock grown from seeds of sour Orange and budded with sweet varieties. The last is rapidly becoming very popular. The sour stock is not so liable to some diseases that attack the sweet stock. It is more hardy; it grows more rapidly; fruits earlier and more abundantly; and some of us think we can detect a spiciness and richness of flavour not found in fruit budded on sweet stock. As a rule, the budded stock is now preferred to the sweet seedling, because the trees come into bearing sooner.

In saving the seed for planting care should be taken to prevent their becoming dry, as they are very hard to germinate when once thoroughly dry. When taken from the fruit they should be put at once in a box containing moist earth, and so kept till time for planting. Care should be taken not to keep the soil in which the seed are placed so warm as to cause them to sprout before the time for planting.

The best result the writer ever had in obtaining a good stand of plants, the fruit was allowed to decay in barrels till the seed readily separated from the fruit. The seed were then washed out and put into a barrel with alternate layers of moist sand. Careful watch was kept over the seed to note the first indication of sprouting. The land for the nursery was then laid off with a plough, and the seed dropped in the furrow and covered to a depth of 2 inches. They came up as readily and uniformly as corn. When the plants are 3 or 4 inches high they should be drawn and transferred to the nursery, and set at a distance of 6 inches by 24 inches. If well cultivated and fertilised, they are ready for budding the second or third year. The buds can be put in at any time the sap is flowing readily, which is indicated by the bark being easily separated from the wood by the point of the knife. If the bark does not part readily from the wood, better stimulate your trees by giving them a good dressing of manure and good working, as these will soon start the sap and help the trees.

It is usual to set out trees into the fields one year after budding. But, with as good results as I have known, the buds were inserted with last flow of sap in the fall, remained dormant during winter, and during the next spring the sap was allowed to start only so far as to swell the buds, when the tree was cut back to within an inch of the new bud, and transplanted to its position in the field. In four years thereafter some of the trees were in bearing. Distances between trees in the grove should vary with the character of the tree to be planted. Twenty-one feet distance between sour-stock budded, twenty-five between sweet-stock budded, and thirty between seedlings, are good distances to observe.

Of course, the better prepared the soil in which the trees are to be set, the better the results will be. If time and means are at the command of the planter, it is best to take up all the stumps and thoroughly break the ground, by giving to it several ploughings and harrowings, till the surface is well levelled. If the stumps are allowed to stand upon the ground, they will, for some years, hinder and add to the cost of cultivation. They will further furnish a cover for insects, and food for the white ant, or "wood-lice," which, as the dead wood disappears from the ground, force the white ants to feed upon the roots of the Orange trees, frequently with fatal effect to the trees. Thoroughly levelling the surface will enable the planter to set his trees at a uniform depth.

The richer the soil is made, provided no manures are added that will induce fermentation, the more rapidly the trees will grow, the better will they resist the influence of disease, insects, and cold, to which they are subject. Fertilising should be done in the spring or early summer, so as not to induce a late and winter growth of new wood, which would subject the trees to damage from frost. The trees should not be set deeper in the soil than they grew in the nursery. It is better to set them a little high than too low. This rule should be observed especially in low or flat lands.

### PRIMROSES AND PRIMROSES.

"A Primrose by the river brim,  
A yellow Primrose was to him,  
And it was nothing more."

THOSE Primroses by the river brim or from the woodland's shade differ materially from the Primrose of the garden. Unless the garden Primrose can have its habitat under as nearly as possible the same conditions as it enjoys in a natural state its form becomes smaller and more circular, the colour is not so deep, and the perfume not so sweet and distinct. In large gardens where each specimen may have its own space and its own treatment such deterioration may be avoided; but in a small garden where Roses are more the consideration the Primrose sometimes suffers from contact with the richer soil required by the Rose in the way I have described; and it is refreshing to scent and sight to see the genuine stars of the woods and lanes in all their delicious glow of the softest and most luminous gold displaying their beauty lavishly around.

I think we are too covetous. Surely smaller quantities might suffice for our decorations in memorial wreaths, and our badge-bunches on Primrose day might out of consideration for the flower so loved by our late

chief be limited. Massed flowers are never beautiful; grouping or arranging (two or three blossoms, a bud, and a leaf) is wholly different, far more pleasing, natural, and effective. One shudders to think how many plants must be trodden, mutilated, even destroyed, to gratify the desire or enormous quantity.—A. M. B.

#### REVIEW OF BOOK.

*Report of Observations on Injurious Insects During the Year 1885.*  
By ELEANOR A. ORMEROD, F.R.M.S., &c. Simpkin, Marshall & Co.

THIS report—the ninth published by Miss Ormerod—testifies to the painstaking and perseverance with which she has followed up her researches, which have made her a dangerous enemy to our many insect foes. It testifies also to the increase of knowledge on this subject amongst gardeners and farmers, many of whom are now becoming careful observers, and ceasing to be led by old beliefs or hasty conclusions. In her preface Miss Ormerod notes the important fact, that by the re-arrangement of the cases representing destructive insects and the results of their operations, exhibited at the South Kensington Museum, an easy plan of reference has been adopted, and the latest information given; and the figures accompanying this report render it of greater value.

Taking the season as a whole, 1885 does not appear to have been one in which horticulture suffered much through the attacks of insects. I have already remarked in these pages that hosts were killed by the unfavourable weather of the early summer. The tribe that specially flourished was the aphid tribe, the long drought that affected most parts of Britain helping on their rapid increase, while also making plants less able to withstand them. During the autumn surface caterpillars were numerous in some places; but Miss Ormerod points out that the snow, by its moist and penetrating influences, doubtless killed many of these that might otherwise have lived on till spring to resume their operations. Of the troublesome aphides of the year, conspicuous was the "collier," or bear species (*A. rumicis* of Linnaeus). In connection with remedial measures for this aphid, Mr. J. W. Crompton suggests the use of alkali waste, a product nearly allied to gaslime, and as efficacious for destroying insects in any stage when worked into the soil. Mangolds and Turnips swarmed with two or three species of the fly, and Cabbages were rendered worthless by *A. rapae*, and also covered in some gardens by the tiny powdered wing, or snowfly. The corn aphid, or dolphin, was very generally reported, both Wheat and Oats suffering, the dry weather aggravating the evil. It was observed that the crops cut earliest escaped comparatively. These were often accompanied by the Wheat midge, *Cecidomyia tritici*. To the Oat crop in Ireland some damage was caused by the grubs of the familiar *Tipula oleracea*. The increase of it these recent years is to be attributed, one grower thinks, to the neglect of deep trenching, and the method of harrowing being often bad. The hardness of the young "daddy longlegs" is shown by their defying lime, soot, superphosphate, and even salt. Turning out cattle on infested ground checks the progress of the insect by their tramping and close eating.

A few years ago rather a sensation was created amongst the growers of Strawberries by discovering that the fruit was preyed upon by several species of ground beetles which had been previously supposed to be entirely carnivorous. Since then it has been noticed that another ground beetle, *Steropes madidus*, eats the roots of the Mangold at night, and on a Fern it actually destroyed about one plant in ten during last June. The larvae of weevils (*Curculionidae*) were also found abundant in the Mangold in several places. From some cause unknown the garden chafer, *Hydrophilus*, or "chovees" (*Phyllopertha*), was plentiful last year, and though the grubs chiefly infest grass lands they occur also at the roots of several garden plants; and besides, the beetles themselves have been taken eating the flowers of our fruit trees. As the beetles generally assemble in parties it is not difficult to kill numbers when we know their period.

Several gardeners reported, it seems, the occurrence of the caterpillars of the small swift (*Hepialis lupulinus*) at the roots of winter Beans. It has also been taken up with the roots of other garden plants, such as the Parsnip, the Lettuce, and Celery. Although the circumstance is not remarked upon in the report, from statements and specimens sent to this Journal the nearly akin insect, *H. humuli*, has been troublesome in gardens as well as on the Hop. Reference is made by Miss Ormerod to another fact, also indicated by these pages, that millipedes or false wireworms have either become much more numerous of late or their ravages are more observed. One curious circumstance is that they transfer themselves from one spot to another, sometimes by a united migration, and a gentleman writes that he crossed a swarm of them along a country road, and shuddered to hear the cracking noise under his feet as he trod, caused by their hard coats. Small in size as they are, most of the millipedes live about two years. The specially troublesome jump is that of the snake millipedes. Salt is found to kill them quickly, though many applications fail. Soot is said to drive them away in disgust.

An interesting portion of this report concerns the farmer more particularly, having reference to the alarming mischief done by the warble or ox fly (*Astus bovis*), not merely commercially, but Miss Ormerod considers the presence of maggots occasions the death of some animals suspected to have been killed by disease. The enormous prevalence of the pest is proved by careful statistics given with regard to hides, and at a certain date, when it is the "warbled season," there are frequently more unsound than sound hides in the market. Although a variety of applications have been recommended as destructive to the maggot it is still more important, if possible, to keep the flies off the cattle, and prevent oviposition. For

this end anointing with train oil, or some compound of it, in the summer is strongly advised.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Early Houses.*—The fruit now swelling and colouring fast will require a circulation of air in order to secure flavour, but it should be given carefully during the prevalence of cutting winds, placing some netting over the ventilators. Finish stopping and tying the shoots. Elevate the fruit well above the foliage by placing pieces of lath on the trellis for them to rest upon, guarding against crowding or shading with more young wood than is needed for next year's supply of fruit. Continue syringing until the fruit commences ripening, and be very careful to employ water that will not leave a stain upon the fruits, some water leaving a deposit of lime that detracts from their appearance. Inside borders should be well watered and covered with light non-conducting material that will keep in moisture until after the crop is gathered. Look after outside horders, and be very careful in the removal of covering until we have a change to warmer weather. The recent winter has proved the value of inside horders, as with a liberal root extension in inside borders the roots are kept in action by the average temperature, and so enables them to take up the greatest quantity of food at a time when it is most wanted. Our experience justifies our strongly recommending inside borders made of sound calcareous loam, resting on a foot of clean drainage, through which water can pass away freely; but care must be taken that copious supplies of water are given at proper times, as Peaches when in full growth in such borders, and presenting as they do a large breadth of foliage to the influence of heat and light, rarely suffer from over-watering whilst failures can often be traced to insufficient supplies. In making horders the greatest mistake is heaping together enormous masses of rich materials, through which a few gross roots pass quickly, soon getting beyond control, and continuing to force up unwholesome food at a time when the trees should be at rest. To avoid this the horders should be made so limited that the roots can be kept within bounds, the materials under rather than over-rich, and manure should always be applied on the surface as a mulching.

*Succession Houses.*—Proceed with the usual routine, and keep the trees in health and vigour by the timely application of water to the roots and foliage, early ventilation, and good mulching. If red spider or scale appear, as they often do near the pipes, an insecticide applied to the leaves with a soft brush will speedily destroy the spider, and its application to the wood with a hard one will remove the scale, provided it is taken in hand before it reaches the foliage. The appearance of the first insect should be the signal for attack on the part of the cultivator, when the moderate use of insecticides would prevent injury. Allow a free growth of wood through the stoning process, and guard against retaining more shoots than can be tied to the trellis.

**CUCUMBERS.**—Where these are growing in houses and hot-water pits the plants should be syringed twice a day, so that every portion of the foliage may receive a thorough washing, which will be the means of keeping the plants free from the attacks of red spider and other troublesome insects. Plants growing in dung frames will not need syringing so often; a sprinkling at closing time will be sufficient on bright days, and none at all when the weather is dull. Give liberal and frequent waterings of liquid manure at a temperature of 75° to 80° to plants in full bearing, and avoid overcropping. Straight fruit being in request, and they certainly are finer-looking, they should be placed in glasses as soon as they have set, or three pieces of wood nailed together make a good substitute. No more fire heat should be used than is absolutely necessary, and with the reduction of fire heat moisture will need to be reduced correspondingly. Make another planting if necessary, so that the supply of fruit may exceed rather than prove unequal to the demand. Attend to the necessary stopping, thinning, and tying of the shoots, keeping up a succession of fruitful growths.

**STRAWBERRIES IN POTS.**—Under the best of management Strawberry forcing is a matter of difficulty at this season, especially where forcing has to be carried on in vineries, Peach houses, &c., where red spider is soon transmitted to the permanent plants if the Strawberries are not regularly syringed and kept well supplied with water at the roots, and in addition to cleanliness a proper supply of fruit is cause of some anxiety. Arrangements should be made so that there may be a succession of plants, and crops that are ripening may be retarded in various ways for several days in case an extra supply is required for particular occasions. The expedients are turning the fruits from the sun, shifting the plants to a north house, or removing the plants from under glass into an airy fruit room or cool shed after the fruits are fully ripe. Much can be done at this season in cold frames with judicious management. All plants that can be accommodated in cold or low-heated pits should have their flower spikes thinned out to the requisite number, and be plunged in coal ashes well up to the glass, leaving room for a circulation of air to play between

the glass and the leaves of the plants, and the forward plants from these structures can always be picked to take the places of those that are ripe and ripening. Liquid manure should be given at every alternate watering to plants swelling off their crops, but care must be taken not to give it too strong, and always tepid.

#### HARDY FRUIT GARDEN.

Trees planted last autumn should already be pushing roots freely into the rich soil of the stations; and if this early root-action can be induced before the swelling buds burst into growth, such growths will be all the more vigorous and sturdy. Due care and attention given now to such trees goes far to ensure a successful first year. But too often do we find newly planted trees making very little growth the first season, simply because precaution is not taken to protect the roots from the effects of drought, and to keep the trees securely in position. No doubt drought does much harm to trees exposed to its baneful influence in a hot dry summer, but it is also very mischievous at this season of the year. It would not be so if the instructions given again and again to mulch the trees when planted were followed. The value of the mulching is so obvious that we might reasonably expect ordinary attention would be given to it, yet it is not so. Repeatedly do we find newly planted trees without mulching, and we also find in such cases a want of intelligent appreciation of the causes of success and failure in fruit culture. No sympathy have we with such easy-going and careless practice; we are bound to go further than this, and to insist upon it that when the work is entrusted to a gardener it is clearly his duty to do it in the best way, and he ought not to undertake such work if he is incompetent. The fickleness of the weather in the first week or two of May is proverbial. A sharp frost on May day did much harm to the blossom of unprotected fruit trees; in some instances Cherry blossom was destroyed and Gooseberry leaves blackened by frost. Small pyramidal or espalier Cherries could easily have had protection, and a little dried fern or other litter shaken upon the Gooseberry bushes would have saved the crop. Continue to guard Peach and Nectarine trees carefully from exposure to cold wind in order to save the fruit crop and to prevent attacks of blister upon the foliage and stems of the new growth. Liberal applications of sewage or other liquid manure may now be given to Strawberries and bush fruit, our object being to assist a full development of the fruit, and this can only be done by beginning thus early with the sewage. Never suffer the household sewage to be wasted, but turn the whole of it to account to impart fertility to the soil. A systematic use of sewage in the fruit garden throughout the season of growth is highly advantageous to all kinds of fruit, and is much to be commended. By giving it to Strawberries now we promote a stout sturdy growth of foliage, large trusses of blossom, and plenty of fine fruit. If, however, we wait till the fruit is swelling before using the sewage it will be too late, for then we can only assist the growth of fruit, which cannot be really fine if the blossom was small and the stalks slender.

#### PLANT HOUSES.

*Aralias*.—Useful decorative species like *A. leptophylla* and *A. reticulata* are often grown too warm, and in consequence become too tall. Plants in this condition may be cut close back, the stem cut into lengths of about 2 inches, and inserted singly in small pots. The pots used should be filled with any moderately light sandy soil, a little sand being placed in the centre for the base of the cutting to rest upon. Give a good watering, and plunge the pots in brisk bottom heat in the propagating frame or under a handlight. In a very short time the uppermost eye will burst into growth, and roots will then quickly be formed. When the small pots are full of roots they may be transferred into 4 or 5-inch pots, and grown on in heat for a time until they are large enough for decorative purposes, when they should be hardened to greenhouse treatment. Cold draughts must not be allowed to strike upon the plants. In this position growth will be slow, and the plants will remain of a suitable size for a long time.

*Dracenas*.—Young stock raised from the root portion of the stem and placed singly into 3-inch pots two months ago, must now be transferred into others 2 and 3 inches larger. These should be grown on in brisk heat, carefully watered and shaded from strong sun. Young stock now in pans must be placed into 3-inch pots. If there is any deficiency of young stock of such forms as *D. rutilans* and *congesta*, stems should be cut up without delay, and if placed in brisk heat will not be long before they are ready for small pots. These varieties in their early stages grow much more quickly in heat than in the greenhouse. It is advisable to subject them to this treatment until they are established in 5-inch pots—a very suitable size, and then grow them in the greenhouse. The growth is slower and more sturdy in the greenhouse than in the stove. The whole of the plants required for winter and spring use must be pushed on, so that by autumn they are suitable for the purpose for which they are required. *D. gracilis*, one of the best for room decoration, will do from this date subjected to greenhouse treatment—that is, all plants that are large enough for decoration. By avoiding cold draughts and watering the plants carefully, they will remain in good condition for use the whole of the summer without becoming too large. Plants that have become too tall may have the tops cut off and re-rooted at once. The heads of this variety will root in brisk heat under a hand-glass without losing a single leaf. When well rooted place them into 5-inch pots, allow them to become established, then gradually harden them, and place them in the greenhouse. Young plants raised from side shoots are the best for table decoration, because their foliage is much narrower than is the case with strong plants. These if not required for

this purpose may be grown on strongly in the stove until they have well-developed heads, when they may be taken off and rooted. Plants of *D. Goldiana* that have been raised from side shoots have always a number of small leaves at the base, which detracts from the beauty of this plant when used singly in vases. The heads will root as freely as those of *D. gracilis* if cut off where the wood is soft, plunged in bottom heat, covered with a handglass, and kept shaded from the sun where a brisk temperature can be maintained. Large-growing varieties, such as *D. Chelsoni*, *D. Baptisti*, and others that have been raised from heads this spring and are now in 7 and 8-inch pots should, if fine specimens are required, be transferred without further delay into 10 and 12-inch pots, in which they will develop into very large plants either for furnishing the stove or various positions in rooms where they can be surrounded with Ferns and other plants of a dwarf nature to form small groups.

*Gardenias*.—Young plants rooted last August and now well established in 5-inch, may be shifted into 7-inch pots. The shoots may be tied out towards the rim of the pots, and in a short time growths will spring freely from the centre. These must be pinched from time to time to prevent the plants becoming straggling. If grown on in heat and moisture they will develop rapidly, and by autumn be 2 feet or more in diameter. For spring flowering, young plants raised every autumn are decidedly better than the retention of old ones. For autumn and winter flowers the best of the old plants should be selected that have their pots full of roots, so that they will only make a dwarf sturdy growth, which can be brought to a standstill early by cool treatment. Where it is necessary to retain the old stock for spring flowering they should be cut close back after the flowers are over, and repotted when they have broken into growth.

*Tabernaemontanas*.—As these plants cease flowering they should be well cut back, or in a short time they soon become bare at the base. If liberally pruned annually they will be well furnished with foliage. When they have commenced growth after pruning they may be turned out of their pots and the old soil shaken from the roots. They can be placed in the same or smaller pots, and if kept in brisk moist heat and shaded from the sun will soon be well established again.

*Aschynanthus*.—These are beautiful plants when well grown, and are much more effective in baskets than when their cultivation is attempted in pots. If cuttings are now rooted they may be placed round the sides of baskets in a compost of fibry peat and loam in equal proportions with charcoal and sand freely intermixed. The cuttings, if practicable, should be rooted singly in small pots, so that they can be placed in the baskets without the risk of checking them. They will then grow away freely, and their shoots will hang gracefully from the basket. Fresh baskets should be made up annually, so that a few of the oldest can be destroyed, for in time the soil becomes exhausted and they then fail to do satisfactorily. The small but free-growing *Lobbianus* is a splendid basket plant, and from this season of the year is most attractive with its dark chocolate and scarlet flowers. All the varieties enumerated in catalogues are well worth growth, but if two only are required select the one named and *grandiflorus*.

## THE BEE-KEEPER.

### NOTES ON BEES.

#### TRANSFERRING STOCKS.

THERE are few bee-keepers nowadays who are content to begin with the common straw skep as they sneeringly term it; the teaching of the day is to a great extent making men believe that it is easy to manage an apiary, and that no particular experience is required in this industry in order to ensure success. To commence with a skep would indeed be a degradation. It is, perhaps, this false idea of the relative merits of the straw removeable frame hive which makes beginners ask so many questions on the subject of transferring stocks from one hive to another. A bar-frame hive, too, looks so neat and compact, and, in comparison with the homely skep, seems quite a palace, so they are all anxiety to change the abode of the bees, sometimes quite irrespective of the value of the hives. Transferring was a few years ago much more prevalent than is now the case, but the evil results induced by so essentially false a practice have effectually prevented its adoption except in the case of men who, from an interested motive or in the pride of new learnt power, venture to remove the combs and bees from a skep and place them in a bar-hive in the spring. It is, perhaps, unnecessary to say that there are some few men who can perform this operation with success, but for the generality of bee-keepers the operation is one often attended by loss which cannot be at all compensated for by any benefit derived from the change of hive, even when the removal is managed in the most successful manner.

possible. It will, however, be advantageous to say a few words upon the subject, and to consider the best way to treat a stock in a common skep with which the majority of bee-keepers are launched into apiculture.

A man who begins his bee-keeping life with a good knowledge of bees and their practical management gained from careful reading of standard works on the subject, which are now not few in number, has indeed a great advantage over another who has to learn by experience what he would in a far shorter time have picked up from a book written by a practical man, who writes solely for the benefit of bee-keepers and is uninfluenced by any other consideration which may induce him to recommend appliances which have not been really proved to be of value and efficacy. Let every man be content to leave his bees in the skep, at any rate until a time has arrived when he can transfer them with absolute safety to the hive which he has provided as he thinks for their better accommodation. This time is twenty-one days after swarming, when the combs will contain no worker eggs or brood, although there may be some few drones still unhatched, but they, however, may be sacrificed, if necessary, without remorse, and even with advantage. The man who allows his bees to be transferred in spring from a straw skep to a bar-frame hive has yet to learn from bitter experience that it is safer to travel slowly yet safely than to hurry unwisely over roads of which he knows nothing, and on which he will be sure to find many obstacles to bar his—as he hoped—rapid progress, and to allow his rival who took the slower but safer road to pass him and gain the goal they both strive in different ways to attain.

#### THE POSITION OF THE APIARY.

One of the most troublesome details in connection with the commencement of bee-keeping is the choice of a position for the apiary. It is difficult because so many things have to be taken into careful consideration, and for the fact that it is most difficult, and at certain times of the year almost impossible, to move a stock of bees a less distance than two miles without the certainty of losing many bees, which, not marking their new situation, fly back to the old position and, becoming exhausted, die there. There are, no doubt, some positions more favourable than others, but it is essential that there be no likelihood of being compelled to move the apiary from the spot on which it is first located. There is no position that seems more suitable than one having a south-east aspect for the bees; these obtain the early rays of the sun, which are so useful as an incitement to early labours, and yet the cutting east wind is to some extent kept out of the hive. A hedge or wall at the back of the hives is also another very useful adjunct, and should in every case be obtained if possible; and if no wall or hedge is to be had it is well to erect either some temporary defence against the northern winds, or to plant trees which will year by year afford a more complete and perfect shelter. In front of the hives no trees or bushes should be allowed to grow, and no herbage to rise higher than the floorboard, for by branches of trees and bushes many bees are in high winds dashed to the ground and are unable to rise again. If, then, the hedge behind the clear space in front and a south-easterly aspect can be had, an almost perfect situation is formed for the apiary; but it is not by any means necessary to insist upon having any particular location, as even in the very worst positions the bees will so far overcome their unfavourable circumstances as to make perhaps but little real difference perceivable.

#### RACES OF BEES.

There are, again, few bee-keepers who are able to withstand the temptation to invest in some new variety of bee which will work wonders and astonish the old-fashioned bee-keepers who retain the blacks, which are now as a matter of fact rapidly becoming extinct, owing to the number of foreign varieties which are being introduced into apiaries in all parts of the kingdom. It is no doubt very beneficial for bee-keepers who desire to experiment to try many varieties of

bees and to give their experience to the world, but for a practical man who desires to make money by his bees it is far from wise to import a foreign race until he is perfectly satisfied that he will get something superior to what he possessed before. The foreign varieties are often better-looking than the native or the crossed varieties, but good looks are not what we want at all. We want extra work, more honey at less expenditure of time and money, and any bee which will give us this result will be warmly welcomed. The Ligurian bee is supposed to have these most desirable qualities, and there are other varieties of which the "Lanarkshire Bee-keeper," than whom there is no safer guide or greater authority on bees, has given some good accounts, but at present I see nothing in any variety so far superior to what we already possess in the common bee to enable me with confidence to recommend bee-keepers to take it into their apiaries. The common variety does so well that it will be difficult for any other variety to eclipse it, although it is quite possible that a careful cross between some two varieties may give a bee superior to any one of the pure races; but in all crosses there seems to be one great disadvantage in the increased tendency to use their stings, which seems to be developed in the progeny of hybrid queens. It is, however, necessary to say a few words on the other side, for I quite agree with a passage in some bee book which complains that a fair trial is not given to the foreign bee in many apiaries. Great expectations are raised, but the new queen is imported, perhaps to fill the place of a queen deceased in a poor colony, and is expected to restore to prosperity a hive which was worthless from the commencement. Another great fault in connection with foreign bees is that many bee-keepers divide them so unmercifully that the wonder is, not they do not collect a large surplus of honey, but that they contrive to exist at all. Disease does indeed often ensue, and then the race is condemned as worthless. Fair trial must be given to all, and until such trial has been made no condemnation can be fairly uttered. If the Ligurian bee or the Syrian bee can surpass the common bee in the hands of an ordinary bee-master, and has no defect which will depreciate this valuable characteristic, then practical men will readily adopt the change, and those who introduced the variety at expense and no doubt some loss to themselves will have earned the thanks of all bee-keepers.—FELIX.

#### THE SEASON AND THE BEES.

WINTER still lingers with us, and on the last day of April the thermometer stood at 25°, on the day before snow fell for some time. There has not been more than six days free from frost this year, and on three days only have the bees carried natural pollen briskly. Monday, April 26th, was a fine day with a temperature of 65°. On that day five miles from my home I saw wreaths of snow and Crocuses in full bloom.

Vegetation as well as bees are as a rule fully a month later than the average, but at the last a good change has favoured agriculturists and gardeners, and although rather late if heat comes plants will grow fast. Bees that have been well provided with stores and otherwise well cared for at the end of the season are well advanced, it is those only that have been neglected in some shape or other that are behind. My own stocks are mostly in an advanced state, the crossed Cyprians again taking the lead, but both pure and crossed Carniolians as well as crossed Syrians are not far behind. In fact, several nuclei of crossed Carniolians which occupied but one comb beginning of August, and having their hive extended to twelve large frames, stood so all winter and spring, are making more rapid progress in proportion to the number of bees than hives that had a full complement of bees at the end of the season. How is this? Simply because I provided the bees with plenty of honey and pollen, the industrious little insects did their best, and by molesting them no further I did the next best. I have often heard of the evil of pollen-bound hives which occur only when a hive is queenless during favourable weather for collecting pollen, but singular to say I never saw nor knew a hive suffer from being pollen-bound, if at the proper season—viz., in autumn. On the other hand, such hives with me were, as a rule, the best by spring. In every hive that I possess I can recognise bees that were working in July last year. This is by no means uncommon. The only thing uncommon about it is many bee-keepers fail to preserve the adult

bees by the strain they put on them through untimely and stimulative feeding and other manipulations, thereby wearing out and killing their bees prematurely, attributing this to the natural short life of the bees, and not to their injudiciousness.

The proper wintering and preserving of bees from July till May is still to many bee keepers a mystery—a puzzle difficult to solve, which they seek to find out by employing the very opposite means towards a successful issue. There is not a hive of my own that has suffered from the cold and protracted season, which we hope is nearly closed, unless the pure Syrians, but these bees were not located in deep hives as has been the case with a Carniolian hive standing next to the Syrian one. This is the hive that I have alluded to before, and has attracted my attention during the whole season. It was a swarm in July. It made weight rapid, and a few pounds of sugar at the end of the month was all the attention it had, if I except the re-arranging of its covering on the top of frames. During the month of October it made a desperate attack on some hives to rob them, which bees with an aged queen are more liable to do than are those having a young one. After that they clustered up, and during the mild weather in December when other hives were flying, and even working, not a bee of these Carniolians attempted to fly. Neither did they on the 7th February, when others did so a little, and even after the 27th and 28th March when most others took an airing they stirred but little. Not more than a hundred bees flew out until the 22nd and 25th April, when they had a thorough airing and worked well. Many young bees played out at same time, and notwithstanding the six months confinement the dead bees did not exceed a dozen, and there was not a speck of excreta to be seen, neither inside nor outside the hive. Neither was there a single thing to be seen amongst the debris on false floor suggestive of dry excreta, as some writers will have us believe.

The successful wintering of bees consists in having a deep hive, and airy, but free from draught, well covered above frames, and kept free from external damp. With a hive constructed as above, and having a ventilating floor and sufficient bees, the sun's glare does not affect them during winter; the perspiration passes either upwards through the insensible ventilated crown, or falls through the ventilating floor. The damp atmosphere that must necessarily enter the hive is speedily heated, and the whole moisture is carried away by the above agents, while the bees are not affected by damp from any cause whatever. When bees are kept in such a comfortable state as this they remain quiet, and in that peculiar state of semi-torpor so suitable for preserving animal life during cold weather, feeding only at suitable times, and seemingly when full or satisfied the contents of the stomach are wholly consumed with little or no refuse to pass off as excreta, but is spent entirely to keep up the heat, the refuse passing off in carbonic acid gas and water through perspiration. I have not the slightest hesitation in saying that the successful wintering of this and my other hives is due entirely to the management I have laid down in these columns, and is what every bee-keeper should aim at.

Queen-rearing will be our first work in the apiary, and to all appearance three weeks hence we will be able to begin. I shall breed first from pure Carniolians; and in order to be in time, if the hives selected are not the most forward, I will exchange combs with those further advanced for some from my selected queen-raisers not so far advanced. By this means I shall have queens ready to introduce to others when they swarm. The remainder I will put in hives holding four nuclei, and nurse these on to be in readiness at any time a queen is wanted. By pursuing this course, and keeping up the strength of the apiary by constant breeding, all my hives will be in full strength during summer, and extra strong for the Heather. As strong hives are those only that collect large quantities at the moors and pay the expenses of taking them there I will take up this subject again, but advise bee-keepers to push forward one hive at least to be in readiness for swarming early and queen-rearing.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We

request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**TO CORRESPONDENTS.**—We desire to assure those of our correspondents whose letters and communications are not promptly inserted that they are not the less appreciated on that account. Our pages are practically filled several days prior to publication, and letters arriving on Wednesday morning, except by special arrangement, are invariably too late for insertion. The delay in the publication of some of these is not of material importance, but reports of meetings and shows held a week previously lose much or all of their value if not received in time to appear in the current issue.

**Books (Warwick Square).**—The best cheap elementary work on botany is the primer by Sir J. D. Hooker, issued as one of a series by Macmillan. The system of arrangement adopted in Lindley's "Vegetable Kingdom" is a good one, but modifications of Decandolle's and Jussieu's systems are also adopted by some botanists.

**Trough on Flue (E. M. H. C.).**—The trough on the flue beneath the box without a bottom ought not to be kept filled with water, as the soil or drainage will be in contact with it and absorb the water, and so become sodden and sour. If the box had a bottom, then you might have kept the trough filled with water or liquid manure to supply moisture to the atmosphere.

**Cesspool (F. J.).**—Throw plenty of gypsum (plaster of Paris or sulphate of lime) into the tank. The liquid must not be used thick, like cream, and leave a scum on the surface, but must be diluted when in that condition. We intended appending this to the last reply we gave on another subject, but omitted to do so. If both the questions had been in the same letter they would have been attended to.

**Show Auriculas (H. E. M.).**—It is not customary for growers to raise seed for sale of choice named varieties, as the ripening of much seed weakens the plants. We know of no other way of establishing a collection of the best named stage varieties than by purchasing plants from florists. Some Show varieties are faithfully represented on page 315.

**Cinerarias (E. G.).**—The flowers sent represent a very good strain, and, judging by the description of your plants, they must have been admirably grown. Though the varieties are of full average excellence as obtained from purchased seed, not one of them would be rewarded with a certificate by the Floral Committee of the Royal Horticultural Society. The florets do not overlap sufficiently nor possess the requisite substance. The Auriculas are types of ordinary border varieties.

**Tank Leaking (W. M.).**—We are glad to have your experience, which solves the problem that puzzled you and the architect; undoubtedly the floors of tanks must be quite firm to avoid sinking, and the builder's idea to have them convex is good, but they must be firm all the same. It is scarcely within our province to settle disputed points between architects, builders, or gardeners on general matters not pertaining to horticulture. If you fill the space with dry powdered charcoal and limewash the outer roof—indeed, being wood, it should be covered in the same way that "Lanarkshire Bee-keeper" covers his hive (see page 262)—you will secure a more equable temperature in the larder than by either of the plans to which you allude. We do not desire the name of the architect. These gentlemen differ in opinion occasionally, the same as doctors do—and gardeners.

**Covering a Lawn Tennis Ground with Cinders (Merchant).**—For covering the ground you should have at least 3 inches thickness of the red cinders, the remainder of the foot thickness should be of the black cinders, with clinkers, &c., and the whole rammed as firmly as possible, so as to prevent sinking or settling after the work is done. The cinders will not be of any use for lawn tennis as the frost will disturb them. The surface should be cemented, the top 3 inches being formed of cement concrete in the proportion of one part Portland cement to two of the red cinders, brought to the consistency of mortar with water. The surface should be smooth, and have a slight incline outward every way so as to keep it clear of water, but the fall must not be much or it will spoil the ground for playing. About an inch in 12 feet is sufficient.

**Crowded Vines (Constant Reader).**—It is not necessary to publish your letter. When Vines are what is known as "long pruned," though they often show finer bunches than by close spurring, evil is certain to follow if the growths are not thinned by disbudding. Every lateral must have space for the leaves to develop fully without being crushed and shaded by others, and the earlier this disbudding or thinning is done the better. "Long spurs" when cut back are followed by fresh growths if the Vines are strong; but if weak the growths, if produced, are weak also. If the laterals are anything less than a foot apart cut every alternate one back to the main rod, and whether fresh growths issue or not the Vines will be improved by the thinning. If they do not bear well on the close-spur system, train up some young rods under the fullest exposure to light possible. When the roots of Vines are matted near the surface of the border and well supported, the laterals also trained thinly, Vines usually bear well when closely pruned. If the roots are far beneath the surface and the Vines make long-jointed wood, close pruning often results in small bunches, or none at all if the Vines are weak.

**Potting Azaleas (E. D. Wicklow).**—It is only under very exceptional circumstances that the old balls of soil should be broken and reduced. The soil in which they should be potted must consist of peat and a liberal dash

of coarse sand. When potting them, which should be done just as they are starting into growth, the soil used should be pressed firmly into the pots. Care must be taken to do this, for if the new soil is not made slightly firmer than that of the old ball, water will pass through the new soil and leave the old ball dry, which would soon prove fatal to the plants. They should be most carefully watered at their roots, and never allowed to become dry in any stage of growth. The foliage must be liberally syringed during the greater part of the year in order to keep it free from thrips, an insect very troublesome to these plants. After the plants have flowered they should be encouraged to make a good growth by keeping the house in which they are growing close and moist, the plants being well syringed in the morning and again in the afternoon, also shaded from bright sun. After the growth is completed they should be hardened, and may be stood outside until September, when they should be housed. Before placing them out the flower buds will be formed. While outside be careful that the sun does not strike direct upon the pots, or the roots, which are very fine, will be destroyed. Portions of old mats secured on the sunny side of the pots will protect the roots from injury by the sun. Camellias require much the same treatment, but removing loose or sour soil from the roots, and using half loam or more, not containing lime, and a little crushed charcoal. Avoid overpotting, and drain effectively, so that copious supplies of water can be given without rendering the soil sour.

**Roses in Pots (D.).**—Mr. Ladds, to whom you refer, grows all his Tea Roses in large pots, but many other growers have them planted out. The latter plan gives the largest blooms, but those in pots are more useful and admit of the house being put to other purposes when the Roses are outside. The only way to get large blooms is by good feeding, and for this to be of any avail the plants must have active roots; therefore the plants must be established in a good soil, and with plenty of roots there is no difficulty in increasing the size of the blooms by rich surface dressings and the application of liquid manure. All the artificial manures are good. A little of any of them sprinkled on the surface of the pots and washed in will make a great deal of difference in the growth and size of the blooms. Bone-meal is a capital dressing for Roses in pots, and Beeson's, Clay's, Jensen's, &c., are capital fertilisers. A surface dressing of manure, to which a quart of bone-meal and a quart of soot have been added and intermixed with half a bushel of the manure is first rate, applied as a surface dressing about an inch thick, and renewed from time to time as it becomes reduced or wastes away. Liquid manure should be given once or twice a week, than which there is none better than cow dung put in a sack or coarse bag, and at the rate of a peck to 30 gallons of water. If no surface dressing is used containing soot, then add soot also in a bag at the rate of a peck to 30 gallons of water or 60 gallons for the peck each of cow dung and soot. No pruning is necessary, only any weak worn-out wood is cut out to encourage young and strong growth, on which the finest flowers are produced.

**Substitute for Wood Ashes in Compost for Chrysanthemums (J. L. J.).**—The potash of commerce will hardly do for mixing with the soil for Chrysanthemums. It would be much better to apply the potash as surface-dressing and in combination with other manurial substances, as potash is not all that is required to ensure a good clean growth, and there is danger of disaster from too much potash; indeed, all salts require to be given in small supplies, and not too frequently. Urine contains potash largely, and we find that the drainings of stables, diluted with six times its bulk of clear water, sufficiently powerful for Chrysanthemums if given twice a week. Amies', Clay's, Beeson's, Jensen's, and other advertised manures contain potash. You may use any of these with safety, and as we have proved with benefit for mixing with the soil at potting at the rate of a quart to a bushel of compost, and if you use calcined oyster shells or crushed bones, or drainage an inch thick over the two or three large pieces of crocks at the last potting, nothing more is wanted in the soil, as the chief thing is to get a good rooting medium and feed with liquid or rich surface dressings. A teaspoonful of sulphate of ammonia to three gallons of water is the best liquid we have used, it being applied once a week; the other waterings being of animal manure and soot, one peck each to sixty or seventy gallons of water, and the drainings of the stables, mostly urine, diluted with six times the quantity of water. The plants, therefore, were watered every other day with stimulating food—viz., ammonia water, cow manure, soot, and stable tank water, and on other days with water only. Surface-dressings are excellent, but they must be used judiciously and not frequently, or at intervals of ten days to a fortnight; less frequently in moist and more frequently in dry weather. If highly fed in wet weather the plants attain a luxuriance which is not sustained in dry weather, and the flowering is considerably affected. The thing is to get a sturdy growth thoroughly solidified or ripened, and then fine blooms may be relied upon. As a surface dressing, six parts superphosphate of lime and one part each of sulphate of ammonia and potash of commerce is likely to form an excellent stimulant, but we have not tried it sufficiently to warrant our confidently advising its use. It should be used in moderation, about a teaspoonful on the surface of a 9-inch pot, and the surface scratched a little with a label after its application, and then washed well in with a rose watering-pot.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (Bishop).—1, New Bess Pool; 2, Winter Greeving; 3, Not known.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (C. L.).—*Oxalis rosea*. (H. Coombs).—*Aspidistra lurida variegata*. (W. C., Peebles).—It is a stunted specimen of *Abies nobilis*.

#### COVENT GARDEN MARKET.—MAY 5TH.

Good supplies of Grapes now reaching us at reduced prices. Strawberries inclined to advance.

#### THE FUTURE OF FARMING.

WHEN the full value comes to be known generally of the constituents of artificial manure, and farmers are able to distinguish between nitrogenous, phosphatic, alkaline and calcareous manures, and the relative value of each fertiliser and its particular use as plant food is known, the somewhat vague term of artificial will probably give place to the more appropriate appellation of chemical manures. The mere use of manures has been termed "Adding artificially to the fertility of the land." Why artificially? If we assist Nature in the right way she contributes materially to the fertility of the soil, but in order to obtain all that is possible from it we must make good each element of fertility in which it is deficient, and to do this as economically as possible we must know what was taken from it by the last crop, what will be required by the next one. In the acquisition of such knowledge we need not at the outset trouble ourselves much about

geological formation, but rather strive earnestly to ascertain the chemical composition of the plants we have to cultivate, and see that sufficient of each fertiliser required by a given crop is present in the soil for it, a little watchfulness and care will then soon clear the way of difficulties. We refer to this important work in its bearing upon the future of farming thus in general rather than particular terms, because for practical purposes it is unwise to carry scientific nicety to a ridiculous extreme. Whatever rules are framed for the guidance of farmers generally must be elastic to be generally applicable to practice.

Instead of placing blind reliance upon stringent rules, let there be intelligent individual effort to acquire sufficient knowledge for confident independent action, according as local circumstances may require. To be really successful a farmer must look closely into cause and effect. Dare we venture to assert that the ordinary farmer does so? On the day of writing this article we called the attention of the home farm bailiff to the general flourishing appearance of a field of winter Oats. He, without any hesitation, said it was owing to sheep-folding and farmyard manure, yet ample evidence that he was wrong lay clearly before his eyes, if only he could have seen it.

The Oats had a half dressing of home-mixed artificial manure in the autumn, the other half dressing was given early this spring. It was sown broadcast by hand, and like most hand work it lacked the precision and nicety of machine work. In several places were strips of Oats which had been missed by the manure sower, and the poverty of growth was all the more remarkable from the vigour of that which had the full benefit of the spring dressing. A noteworthy fact of this field of winter Oats—a deep loam in mid-Suffolk—is that we have used a precisely similar prescription of home-mixed manure to that which we used in Sussex for a poor thin silicious soil on the Hastings sand formation, and apparently the results will prove equally satisfactory. Eventually we hope they will surpass them, but it must not be forgotten that deep loam may be lamentably poverty stricken, and the mention of this brings us to another important consideration for the future of farming, which is soil management.

A wide field opens before us here, but our remarks must be confined to a few leading general points. It may be laid down as a fundamental rule that drainage is necessary for all soil upon clay, marl, or mixtures of a tenacious character. We must relieve the soil of superfluous surface water, we must also prevent water contained in the subsoil from rising to the surface by capillary attraction. The mention of such self-evident facts is like the repetition of an oft told tale, and yet how necessary is it that we should never miss an opportunity of telling how waterlogged soil is always—aye, even in summer—at such a low temperature that no crop can really thrive in it, no matter how heavily it is manured. We have done much good work in draining wet land during the past winter, and we hope to tell of favourable results arising from it in due course.

Mechanical division of the soil is another cultural point to which full attention must be given in the future. Farmers in a gravel or flint district have no trouble in this matter, but there are very few stones to be found in soil resting on sandstone, and it is liable to settle down into so compact a mass that air and moisture enter it very slowly. Dressings of burnt earth, coal ashes, and lime afford an effectual remedy for such a serious want of division in the soil. When this is set right, cleanliness is the next point to which close attention must be given. Soil infested with foul weeds is unfit for the growth of farm crops, and it must be made clean before we can possibly avoid waste in cultivation. Advisedly do we place cleanliness before fertility. We cannot afford to waste manure upon the culture of weeds. Carelessness and slovenly practice generally has caused couch grass and Charlock to spread far and wide over the land. Couch grass is an insidious enemy of which little is seen till we turn up the soil, but Charlock plants its yellow blossom in our eyes so that

we have no excuse for allowing the first few plants of it to run to seed among the crops in which they first appear on the farm. Every yellow-flowered rogue should be destroyed while yet they may be counted by the hundred, but if we let it alone for a season or two it spreads with such rapidity that it is not easily got rid of.

(To be continued.)

#### WORK ON THE HOME FARM.

Time which could only be spared with difficulty has had to be given to chaff-cutting for the flock. Rye, Rye Grass, and Meadow Grass all grows fast now, but the sheep still have chaff in the folds with other mixed dry food. Before all things the ewes must be kept in healthy condition if we would have the lambs answer, and it is by no means easy to manage this now, for fast-growing lambs, however well fed, make heavy demands upon the ewes, evidence of which is seen in every one of the dams, but especially the weakly ones. On the day of writing this note we sent our first hatch of fat lambs to market; some were sold for 32s. apiece, others at 27s., and others at 25s. Such prices afford a handsome margin of profit upon outlay for lamb food and labour, and we certainly could never sell them to greater advantage, however long we might keep them. In proof of this we may add that at the same market we had forty fat hoggets sold at prices ranging from 47s. 6d. to 50s. 6d. apiece. They were about a year older than the lambs, and had consumed much corn and cake last winter. No doubt much good was done to the land upon which they were folded, but it is clearly worth while to have a few score fat lambs early in market. One more lesson gained at market to-day among the sheep. Among the fat hoggets were a considerable number of prime pure-bred Suffolk hoggets, black faced, with fine long thick frames, and in high condition. Pen after pen of five hoggets was sold at prices ranging from £15 to £17 10s. per pen of five, or at an average price of 65s. apiece. Of course they had been well fed, but then it was equally clear how admirably they had ripened for the butcher. Again we say, if you do keep sheep or cattle keep the best, best in the light of profit and loss, for that is the only safe test, and is that to which all our practice and its results should be subject. We do not care at all about pedigree stock, but we certainly do care for that which can be turned into profit quickly.

Dairy cows are let out on meadow grass in the day now, but they will be kept in at night for another month. Store cattle will not leave the yards till the pastures are forward in growth. We have no faith in turning out beasts upon half bare pastures, for the result is never satisfactory. What is known as store condition among cattle never did point to speedy profit at the best, and now less so than ever. If we do have cattle upon the farm our only safe course is to keep them from falling into low condition at any time, but we must not go to the other extreme, and force them so fast as to run a risk of losses from quarter evil.

**A DAIRY SCHOLARSHIP.**—A sum of £20 is offered by the British Dairy Farmers' Association to provide a scholarship, to be competed for by dairy farmers or persons intending to start upon the business of dairy farming or dairying. Candidates must be not less than eighteen years of age. They will be subjected to a written and a *visd voce* examination in butter-making at the Society's rooms, 191, Fleet Street, London, on Thursday, May 13th, and a practical examination at Mr. Tisdall's dairy, Kensington. The successful candidate will be required to devote at least two months to the acquisition of knowledge of butter-making in Normandy, and to keep a journal of his experience during the whole period of his scholarship, sending a copy of it weekly to the British Dairy Farmers' Association.

#### REMARKS.

25th.—Almost cloudless day and night.  
 26th.—Another cloudless day and night.  
 27th.—Again almost cloudless.  
 28th.—Wet early, with sharp hail shower at 4.15 A.M., but a fine day on the whole, with some sunshine and occasional showers.  
 29th.—Wet early, dull morning, fine afternoon and evening.  
 30th.—A glorious spring day.  
 1st.—An exceptionally beautiful day.  
 As a whole a week of exceptionally bright clear weather, but with rather treacherous E. or N.E. wind. Temperature rather lower than that of the preceding week, and a little below the average.—G. J. SIMONS.

### PLANTING VINES AND EARLY FORCING.

**T**HE old practice of planting Vines when dormant, or just as they are breaking into growth in spring, has almost become one of the systems of the past. It would doubtless die out if the convenience existed in all gardening establishments for raising young Vines and planting them out in a growing state. Varied circumstances often prevent this being done, and therefore the good old system is resorted to in many cases with the most satisfactory results.

However good or reliable the practice of planting ripened canes may be during the resting period or just as they are starting into growth, it cannot be favourably compared with planting young Vines from eyes in a growing state. Young Vines planted during the months of May, June, or July in a border prepared for them become thoroughly established before winter, and the second year make a stronger and better growth than would be the case if grown in pots for the whole of the first season. Nearly one season is saved by planting in a growing state, and the crop of fruit the second year will be nearly double from the temporary Vines what would be had from Vines turned out of pots and planted during the winter and spring. Planting when growing during the two first months named is only practicable where the Vines are home-grown for the purpose, and the greatest care is necessary, even under these circumstances, in preventing their being checked by removal from the house in which they have been growing to that in which they are to be planted. If they are purchased during the two former months, and have to travel any considerable distance they are almost certain to be seriously checked, and may be thrown back a whole season or more; the same progress will not then be made the following year as would follow if ripened canes were planted during the winter.

When Vines are home-grown for planting they may either be grown in pots until they are planted out or without them. Either plan answers admirably, but I prefer to grow them in pots until they are ready for transferring from 6-inch to a larger size. From this stage, instead of placing them into 10-inch pots as is usual, I would rather place them in boxes 15 inches long, 7 inches deep, and 12 inches wide, with one moveable side, or plant them in soil arranged on large slates. In each case a whole sod the size of the box or slate should be placed at the base, so that they are easily slipped into the border without breaking the ball. From the time they are placed in boxes or planted upon slates they are better grown without the aid of bottom heat; they will not grow quite so rapidly, but they are none the worse, and are less liable to receive a check when planted in the border. When the canes are 2 or 3 feet in length it is a good plan to top them and remove the first lateral growth from the last expanded leaf. This will compel the main bud from the axil of the leaf to push and form a leader. The young Vine for a time appears to stand still, but it is making roots in

quantity, and when the uppermost bud bursts again into growth the Vine will grow with increased vigour, and in strength will surpass untopped Vines. The base of the topped Vine will thicken very much more than those allowed to extend 5 or 6 feet before they are pinched, and the eyes at the base will be much more prominent and break with greater freedom the following season. When they start into growth after being topped they should be removed to the house in which they are to be planted. The temperature should be the same in their new quarters as that of the house from which they have been removed. Before planting them out they must remain in the house, standing upon the border, for a week or ten days, until it is certain they have not been checked by removal.

Planting is a simple process, for they can be slipped from the boxes or slates into the border without disturbing a single root or breaking the ball. A good soaking of thoroughly warm water should be given, which will remove any doubt of the Vines being checked by the temperature of the border being lower than that of the house. The young Vines with plenty of root room will grow rapidly, and those intended for fruiting the following season may be pinched when they are 5 or 6 feet in length and not allowed to extend further. The others may also be topped and then allowed to lead away again and extend to the top of the house if they can be thoroughly ripened; if not, extension may be prevented in order to attain this desirable end.

If Vines cannot be home-grown and planted out as advised they may safely be purchased in July or the following month, when the length of the cane has been developed and has commenced to turn brown at the base, without fear of their being seriously checked, provided they are hardened for transit and the whole of the main foliage preserved. It is much preferable to obtain Vines in this stage of growth and plant them out than to delay planting until the canes have ripened and the foliage has fallen. The balls of roots of such Vines when planted should not be broken or disturbed, for if the soil is pressed firmly round them the roots will quickly and freely enter the border. If an attempt is made to spread out the roots more harm than good will result. The notion that Vines seldom do well when planted with the balls of roots as turned out of the pots has no foundation in fact, as can readily be proved by existing Vines so planted. A moderately close moist atmosphere for a week or two after planting will soon excite such Vines into activity, and they will become well established in the border before winter, ready to make a vigorous growth the following season. When planted during the last month named, it is not wise to allow their growth to extend beyond the formation of a few leaves on the sub-laterals on each side of the Vines and at the top. If planted a month earlier more latitude in this respect may be allowed. It is surprising how the Vines will become established by the development of a few leaves only. From Vines planted during these months a very good crop of fruit may be taken from the temporary ones the following season, provided the canes were well developed and moderately strong when planted. Next to planting Vines that have been home-grown and 3 feet in length we prefer the system detailed to any other that we have practised.

Vines raised in one season from eyes can be thoroughly ripened, and will produce a good crop of fruit if they are not started into growth before January. When planted between Vines intended to form a permanent vinery they are very seldom started so early. The later they are started in the season the stronger they break into growth, and swell and finish much finer fruit than when pushed into growth early. Nowadays ripe Grapes are required by the end of April or early in the following month, and for this purpose Vines grown from eyes in one season are unsuitable. They are very often grown in pots for the supply of the earliest Grapes, but the crop from them so early in the season is not of the most satisfactory description. When subjected to such early

forcing they are generally prematurely ripened and robbed of that season of complete repose which is essential to success. It is almost impossible to ripen them naturally and rest them properly if ripe fruit is required in April or early May. They are frequently rested prematurely by being turned out of doors, and then, instead of being rested, are forced again into growth by the influence of strong heat. If started with a temperature of 45° to 50°, as often recommended, they will rest, and continue to do so for several weeks after they are started before they display the least signs of moving. What else can be expected? for the canes have not thoroughly lengthened out before the close of May; if no time has been lost, it is August before the cane has thickened and developed into full size, then it has to be ripened. I have always found that such Vines, whether home-grown or purchased, are unsuitable for the work for which they are required. I do not contend that a crop of fruit, such as it is, cannot be had from them, for I have had to force them on several occasions. Forcing of this nature is hard work, and always attended with much uncertainty. In the hurry to grow the Vines and get them ripened for starting they are not allowed sufficient time, and either fail to show fruit, or, if they do, they fail to bring the crop to perfection.

Vines, from which ripe fruit is cut during the time stated, should have their wood brown and, to all appearance, ripe by the end of May, and Vines in this condition, if the foliage is kept clean, generally retain their leaves long enough in autumn to considerably reduce their period of rest. This being the case with Vines producing ripe fruit, those grown from eyes and the wood not even brown for three months later cannot be expected to give such satisfactory returns as those that are thoroughly hard and ripe by the time they commence to ripen their wood.

The uncertainty of Vines grown from eyes for very early forcing leads me to shift them into larger pots and fruit them for a second and even a third year. This is an excellent plan, and each year the Vines are in better condition than in the preceding one, provided they are allowed room to develop their foliage and are not too heavily cropped. Another, and perhaps a better system, is to plant out the Vines in a narrow border where larger quantities of early Grapes are required, but these must give place to the method I am about to detail where fruit of fine size and quality is required annually early in the season.

For the purpose a narrow span-roofed structure is decidedly better than a lean-to, for the Vines can be so prepared that either side will produce a crop of fine fruit every alternate year. To be successful both sides of the house should be planted in a narrow border, say 18 inches deep and the same width. Planting may be done during any of the months named, but the side intended to fruit next spring should be planted as early as possible. The strongest canes for this side should be selected and planted 18 inches apart, on the opposite side small planting canes may be placed the same distance apart. If sufficient canes are not forthcoming for this purpose, a few that will be well ripened by autumn may be planted in July or August, so as to become partially established in the soil before winter. These, when the house is started, should be pegged on the surface of the border, and from these sufficient strong fruiting canes will be produced to furnish the roof for fruiting the following season. This is a good plan of furnishing the side of a house with fruiting canes without much trouble. The shoots nearest the extremity of the cane and the base will in all probability start away first, but to prevent these taking the lead they should be pinched when about 18 inches in length, and compelled to lead away again from the main eye by the removal of the lateral growth. These canes, in fact, may all be again pinched when they have travelled half way up the trellis. When they reach the extent of the trellis allowed them they should be again pinched, and the laterals stopped from time to time as may be required. These canes will be well ripened in time to produce ripe fruit by the middle of May if the

fruit the previous season has been ripened by the end of the month.

The Vines that have fruited should be syringed and the foliage preserved as long as possible after the fruit has been cut. At pruning time cut these canes close back and allow them to make strong clean canes for succeeding those on the opposite side. This will certainly be their condition if they receive the same treatment as those on the opposite side carrying the crop of fruit. These canes will be fully made by the end of April, and brown from base to the top by the close of May, and, therefore, thoroughly ripe in early autumn for pruning and starting into growth to bear the following season's crop of fruit.

Vines grown for early forcing on this principle can be syringed and the foliage kept clean, which might not be the case if mixed with those carrying fruit. By being fruited only every alternate year they thoroughly recruit themselves and are capable of carrying a heavier crop of fruit without permanent injury, which would be the case if fruited annually. It is surprising what effect a year's freedom from fruit-bearing has upon young Vines, for they recover from the strain of the previous year's work. By this system there is always one side of the house full of fine strong early-ripened fruiting canes, much stronger, and two or three months at the least earlier ripened, than it is possible to produce by raising the Vines annually for the purpose from eyes.

The narrow border with rich top-dressings annually and judicious feeding after the two first years will support the Vines well for five or six years, when another portion of the border, the same width, may be added, which will support them until they are pulled out and renewed. It is impossible for me at present to say how long Vines on this principle will continue to do satisfactorily, but by fruiting one side annually they are easily renewed without disturbing those required for the following year's crop. After the canes have fruited and are exhausted they can be taken out, a portion of the border removed, and then enriched with loam, manure, and other necessary essentials, and the whole trenched and well mixed. Young Vines planted at once in this border would become established before autumn and make strong fruiting canes to succeed those on the opposite side until they are cleared out and renewed.

This is the easiest and decidedly the best method I have practised, and the most certain for a supply of good fruit early in the season. Vines undoubtedly fruit much better from young canes early in the season than they do when grown on the spur system. Vines subjected to the spur system of pruning have failed with us early in the season, and we are not much surprised, for the first leaves nearest the base generally fall early in summer, and the shoots when cut back to these eyes have only a poor chance of producing a good crop of fruit. They are also much more liable to fail if the crop proves slightly too heavy than if the reverse is the case.—WM. BARDNEY.

## PROFITABLE GARDENING.

(Continued from page 329.)

MARECHAL NIEL ROSE.—No garden nowadays may be said to be complete without a plant or plants under glass of this wonderfully popular Rose, and those who have either to make a garden partially self-supporting or who are growing entirely for sale ought especially to cultivate it extensively. The very best positions for it are the roofs of conservatories and greenhouses, it being immaterial whether these be span-roofed or lean-to in form. As a pillar Rose I consider it useless, as each time we tried it a plentiful crop of green fly was the principal result. When trained thinly on a trellis about 6 inches from the glass it is much less liable to be affected by either mildew or green fly; and what is also of great importance, a great variety of plants may be grown satisfactorily underneath, which fact must not be overlooked when calculating the cost and returns. For instance, we find Azaleas, Camellias, Deutzias, Imantophyllums, Ferns, and Palms all succeed admirably under a thinly trained Maréchal Niel, and other Roses in pots have also done fairly well. This being so, no one need hesitate about

utilising the roof of one or more plant houses with every prospect of pleasure and profit accruing therefrom. In every case ample provision should be made for the roots, as unless liberal treatment is afforded in this respect the plants will not long remain profitable. The border may be either inside or outside, and any width, or according to the position and circumstances. If I erected a new house principally for this Rose a small glazed pit, say about 4 feet wide, would be built against the side walls, and this would serve for both the roots of the Roses and for Marie Louise Violets during the winter. Should they be planted in an outside border in a manner similar to Grape Vines both the border and the stems should be protected during the winter, or otherwise they flag badly after cold frosty nights, the check to the flow of sap naturally retarding the development of the blooms, and a few days may make a very great difference in the prices realised. Inside borders, besides being sometimes inconvenient, are more liable to be neglected, and neglected borders mean a weakly insect-infested growth. The borders to be well drained, and from 2 to 3 feet in depth. A suitable compost would be three parts good turfy loam to one of good partially decayed manure, to which may well be added a sprinkling of half-inch bones and lime rubbish. Should the loam be heavy and fibreless, then we would use only two parts of this, substituting one part of either good leaf soil or light garden soil.

Much the finest plants in the country are, I believe, on the Briar stock, but we have them very vigorous and floriferous on their own roots and fairly profitable on the Manetti. It is now too late to move them from the open ground, and consequently those who may contemplate planting at once must purchase pot plants, and these are generally on the Manetti stock. They can also be preparing other plants by budding a quantity of Briars, or, better still, they can insert buds into strong plants of Gloire de Dijon, on which the Maréchal Niel thrives admirably, and is much less liable to strangulation. It is pretty generally known that the Maréchal Niel is a most vigorous grower, the stems swelling more rapidly than do the Briar stocks, the inevitable consequence being an unhealthy swelling at the point of union, eventually resulting in a collapse of the plant. It is owing to this fact that there is still such a demand for both plants and blooms, as if all or the greater portion of those planted long continued healthy the prices would be much lower than they now are. This liability to break down at any time, not only from strangulation on the Briar, but also from canker when on the Manetti, being understood, it behoves cultivators to anticipate it as far as possible. Not only would we not rely entirely but one large plant, preferring rather to have three or four, but we would also have other younger plants ready to take their place directly they are needed. At the present time we have fresh healthy Briar stocks planted in an outside border and taken through into a house. These, budded where they are to remain, will grow away strongly and form long flowering shoots this season; and by allowing a few growths to form on the stem below where budded to act as "stem swellers," these being stopped occasionally and annually pruned, I hope to prevent eventual strangulation, from which cause we have lost two large plants. In whatever position they may be growing they ought never to become dry at the roots, and when the borders are becoming exhausted frequent supplies of liquid manure should be given, as well as an early mulching of good short manure.

With regard to training I shall not say much, as we have no formal plan. The plants are encouraged to grow vigorously and usually branch naturally, the growths being spread about thinly in all directions. Then when sufficient main branches are secured these may be treated somewhat similarly to Grape Vines—that is to say, all side branches to be spurred back directly after the flowering period or at the present time, and this results in the formation of fairly strong shoots, which if well ripened will produce blooms at nearly every joint. The free use of the knife usually insures an abundance of long flowering growths, sometimes 12 feet or more in length, whereas if the pruning is neglected little besides useless spray is formed. When a well-attended plant refuses to answer to the knife, producing a second crop of blooms rather than the desirable strong growths, it is a sure sign of the tree's decay. Plants cut back at this time should be syringed daily, or when the house is closed, and the temperature of the house may well be kept rather above that given to greenhouse plants. In fact the Maréchal Niel house is very convenient for finishing the growth of Azaleas and other forced plants.

It is not advisable to force this Rose at all hard, but if early blooms are required, and these usually sell surprisingly well, recourse should be had to pot plants. I would also advise beginners to largely cultivate pot plants till such times as the permanent plants have furnished the roof. It is rather late for striking cuttings, but there is no reason why the attempt should not yet prove remunerative. At the same time I may state that quite young "worked" plants can be bought in quantity and cheaply

from various nurserymen, and these, if grown as I shall describe below, would prove of good service for forcing. The best cuttings are those young shoots that have recently perfected a bloom. The latter having been cut leaves the shoot about 3 inches or 4 inches long, and this should be shaved off the main branches, using a sharp knife for the purpose, so as to have a small portion of the old wood or heel attached. Dibbled singly and firmly into 2½-inch pots, plunged in a fairly brisk bottom heat, covered with a handlight and shaded from bright sunshine, they soon strike root, and may then be exposed to more light and air. They ought still to be kept growing in gentle heat, being first shifted in 5-inch or 6-inch pots, and then finally into 10-inch pots. One or at the most two strong shoots should be allowed on each, these being properly supported with stakes as they advance. They will be improved by being stood out in a sheltered sunny position for a few weeks, but ought to be housed before cold and wet weather sets in. They may be either trained roughly round short stakes or be tied up the roof of a house, and if the temperature is maintained at about 45° to 50° by night, and 50° to 60° by day, good blooms should be cut early in February, when they would be worth from 4s. to 6s. per dozen, or according to the class of buyers.

It would be a poor plant that perfected less than twelve blooms, and at 4s. each plant they pay well. I prefer to raise fresh plants each summer, the old ones being available for planting against sunny open walls, in which positions they are also profitable. The permanent plants with very little stimulation can be had in bloom early in March, and a second house should keep up the supply till the middle of May; while in an unheated house they can be had still later. Only the very earliest and the finest should be sent to Covent Garden, where they may perhaps realise 4s. per dozen. Hereabouts the earliest with a frond of Maidenhair Fern are retailed at 6d. each, the growers getting 4s. per dozen. Later on the prices gradually drop till they can be bought for 2d. each, the grower getting 1s. 6d. per dozen, the prices always varying, as a matter of course, according to the freshness and size of the blooms. All should be cut when about half opened, in hot weather before that even, and be at once placed in a cool room in pans of water till packed. A friend of mine has cut 2000 good blooms out of a small span-roofed house 30 feet by 18 feet, the average retail and wholesale price being 3s. per dozen, or about £25 in all. This without much trouble or expense in the shape of fuel, and in addition to what grew in the house besides must be considered profitable gardening. I should add that the Maréchal Niel Rose is subject to the same diseases and insect pests as all other Roses, and to these we may allude some other time.—I. M., Somerset.

#### APPLES FROM THE ANTIPODES.

By parcel post this day I am sending you a few Apples which were grown by Mr. James Lang, Harcourt, near Castlemaine, Victoria, and sent by request of Mr. John Carson of Melbourne (late President of the Victoria Horticultural Society), to the care of Mr. G. F. Wilson, to be exhibited by the Royal Horticultural Society.

The Apples, which have reached here in fine condition, were each of them packed in soft paper with cotton wool round, and a layer of cotton wool between each layer of Apples, and were kept at a temperature of 40° all the way. The soil in which Mr. J. Lang grew them was decomposed granite.

Appended is a list of names of the Apples, and I hope the subject will be one of interest to your readers.

Scarlet Nonpareil	Blue Pearmain
Dumelow's Seedling	Merritt's Pearmain
Stone Pippin	Cleopatra
Reinette de Canada	London Pippin
Gipsy Queen	Sturmer Pippin
Perfection (Colonial and non-blighting)	Newtown Pippin
Worcester Pearmain	Munro's Favourite (Colonial)

—EDMUND BAX, Assistant Secretary Royal Horticultural Society.

[The specimens received are splendid—large, spotless, firm, and clear. If consignments equal to these samples can be placed in the markets of Great Britain during May, June, and July, and sold at about the ordinary market prices of English and American fruit, they could scarcely fail to command a ready sale.]

LECTURE ON THE DAFFODIL.—The notes on the Daffodil, read by me at a recent meeting of the Horticultural Club, were given the same evening to the Editor of the *Journal of Horticulture* to use as he pleased. I mention this because they were then in a very rough form, and the labour of reducing them to a shape in which they could appear in print, and which must have been considerable, was undertaken by the Editor of that Journal, to whom I think this acknowledgment is due, and I observe only one erratum, due, no doubt, to my carelessness in making one or two late additions to the notes. In speaking of the different forms of the mouth of the corona in Daffodils I appear to say that crispate refers to the same form as "fringed" or "fimbriate." This is not so, the fringed form

being caused by many deep incisions of the mouth of the corona close together.—C. WOLLEY DOD.

### MARIE VAN HOUTTE.

#### A ROSE SONG.

ONE flower give to me,  
Ere its clear petals all unclose,  
And deepest amber melts to faintest rose  
By love's own alchemy!

I care for none beside—  
Proud-souled Sunflower; Marigold;  
Nor Tulip with her jewelled mantle's fold;  
Nor Jonquil pheasant-eyed.

My love! my little one!  
Flushed, breathless, with the soft sweet snow  
Of her white bosom wrought to crimson glow,  
She bends before the sun.

Tall Lilies smile to her,  
And with their odorous faint breath  
Tell wondrous legends, which she whispereth  
To me, her worshipper.

In old Hellenic days  
My little Rose had lived I ween,  
Half flower, and half woman had she been,  
Yet goddess, too, always.

And none had scoffed at us;  
If Naiad wedded mortal man,  
Calmly his life passed, like her stream it ran,  
With whispers amorous.

And if, perchance, one day  
(Chasing wild creatures in the wood)  
Before the youth some bending dryad stood,  
And love sprang forth from play,

They strove not to make vain  
His loving tendance of her tree;  
And but smiled softly, and spake tenderly,  
"The gods of him are fain!"

But now our hearts are cold,  
And hurriedly our weary feet  
Leave the green woodland for the glaring street,  
Where all is bought and sold.

Yea, if a poet see  
Sweet shadows passing, broken gleams  
Of fairer life than ours—"The mad fool dreams!"  
They shout unceasingly.

Poor dryad of to-day!  
Some ruthless heart had bartered sure  
Thy leafy home for zeal's stern prison door  
Shutting God's light away!

My sun-flushed amber Rose,  
How far a thought of her hath led!  
Yet turn I loving more, where her sweet head  
Lightens the garden close.

What reck I if she be  
Goddess, or maiden, or mere Rose?  
The soul that loveth deeply only knows  
What she had been to me!

—EVELYN M. NOBLE.  
(Evelyn Pyne.)

### AMERICAN BLACKBERRIES.

MUCH has been written from time to time anent the cultivation of the American Blackberries in England, and many attempts to grow them have been made by skilful practitioners, including Mr. Muir of Margam, but without success—that is, not having produced samples of fruit equal in size, quantity, and flavour, as is said to be the characteristic qualities of these Blackberries as grown in America. The fact is our climate is just as unsuitable for growing these to perfection as it is certain other varieties of fruit introduced from the same region, and except in a few favoured localities it is useless to attempt to grow these American introductions. I have frequently seen examples of the common Bramble on the limestone hills in Worcestershire growing as luxuriantly and bearing as freely, and quite as large sized fruit, as I have seen in the case of the best grown examples of the American varieties. The many varieties now in the trade are nearly all identical with each other, and not more than a year since a variety was introduced from the land of brother Jonathan which was proclaimed by the introducers to be a marvellous example of vigour and productiveness, and in fact its merits were such as to place all previously introduced varieties quite in the shade. Wishing to give this novelty a trial, I was induced on the strength of the introducers' glowing description and engravings to order a dozen of "strong" plants, as no doubt many hundreds more besides myself were. Well, after waiting patiently for three months or more, the said plants arrived by parcel post. It was a small bundle truly, for on opening it I found

the "strong" plants consisted of little weak half-dried-up twigs, no thicker than a straw, and about 3 inches long. These were duly planted, but alas! only two survived out of the dozen, the latter making a feeble shoot each of an inch long; nor is there a prospect of my being able to get much better results again this year. It would be interesting to know how many more besides myself were treated in this manner. Surely this sort of thing amounts to something very much like imposition, for the least thing those who were responsible for the introduction of this so-called superior variety could have done was to have sent plants that were alive and possessed of nice fresh roots, so to have enabled purchasers the opportunity of fruiting the plants within a reasonable number of years. At any rate, I do not intend giving any more high prices for new varieties of Blackberries or anything else from that quarter. I am disgusted with the results obtained in return for the amount of time and money expended in their cultivation, and I doubt not that mine is no isolated case.—A KENTISH GARDENER.

### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 351.)

#### LATE CHRYSANTHEMUMS.

CHRYSANTHEMUMS grown to produce late flowers are much appreciated; indeed they are by some more highly prized than the bulk of those blooming at the ordinary time—viz., the middle of November. To have them in perfection at the end of December and early in January the plants require to be specially treated. In the extreme south of England it is not so easy to have Chrysanthemums late as farther north. The seasons are much earlier in the south, consequently the plants come sooner into bloom. Much may, however, be done in furtherance of this object by selecting varieties which are naturally late in blooming. The selection given in a previous issue if adhered to will be found suitable. Nothing would be gained by naming more, as it is better to grow several plants of one sort which is good, than a few of many varieties merely for the sake of forming a large collection.

Cuttings of varieties intended to bloom late should not be struck till February, and the plants should be pinched three or four times to induce a dwarf habit and increase the number of flower stems. The last topping should take place about the first week in July. When bloom buds make their appearance towards the end of September disbud for one bloom on each shoot if good sized flowers are required; but if quantity is the primary object do not disbud so freely. At this stage supply the plants liberally with weak liquid manure, occasionally watering with soot water or any other of the various stimulants now in use. If they can be protected from light frosts keep them out of doors as long as possible in preference to taking them inside, as keeping them out assists in retarding them. A thin covering of canvas stretched on poles at night will ward off a sharp frost. After removal inside admit air night and day freely when the weather is at all favourable. When developing their blooms if at all wet or foggy keep the atmosphere dry by applying a little fire heat, the flowers last much longer in a dry atmosphere than in one charged with moisture. Nine-inch pots are large enough to bloom them in, and the same compost as advised for other varieties is suitable.

#### ARRANGEMENT OF GROUPS.

To arrange a group of Chrysanthemums for home decoration is much easier than arranging one for exhibition; for this reason—the former groups have not to undergo the critical scrutiny of men who have had wide experience in judging in this branch of horticulture by acting in that capacity at many shows where a variety of groups are seen in various forms. To arrange a group for exhibition in the best style requires some forethought and experience, even allowing that the necessary material is at hand which is required. I will describe what I consider is the best method of proceeding. The prevailing fashion is now to have the groups semi-circular or nearly so in shape. The one adopted by the Kingston and Surbiton Chrysanthemum Society is 50 square feet, being deeper in width than length. This Society may safely take the credit of being the pioneers of this method of growing and arranging Chrysanthemums, and some of the best groups that have been seen were staged in competition at its shows.

In preparing plants for the show a clear conception should be formed of what is required to effect the object in view; and it is wise for young growers not having had any previous experience to first arrange the plants at home on a space similar to that assigned in competition; the thread of the matter, so to speak, is then more clearly conceived, and the number of plants required more safely estimated. We will assume, then, that we are at the show and ready to commence operations. The allotted space to be filled is marked out, no matter the size—large or small, the method of procedure is the same. Commence by placing the front line in position. Possibly some growers may think this is wrong, but it is not so, as may easily be found by experience. Very often an other-

wise good group is spoilt by a defective front line. When a commencement is made from the back, and the plants happen to be tall, it is difficult to bring them down in due proportion without exposing too much the supports of empty pots and blocks of wood employed in the requisite elevations. Unless the plants are grown exactly to suit the purpose the plan of commencement of staging from the back is wrong; but if a start is made from the front a uniform range can be secured, and it is easier to build to a given height than one of imagination. As the work proceeds, if the plants are too tall they can go farther behind, and if too short raising is much easier accomplished without the supports being so much seen. If wire supports are attached to the stakes the work of arranging easily will be much facilitated, as any particular flower can be more easily brought into the required position. The height of the front row of plants for a group of the size named should be about 2 feet 6 inches or 3 feet, measuring from the ground; and the back row of plants about 6 feet, sloping evenly from this point down to the front; and from the centre line from back to front the plants should slope a little down to the sides of the group. This relieves the flatness otherwise caused by an even sloping bank from back to front. When quality has to be taken into consideration, as well as arrangement, the best means should be adopted of showing all the flowers on each plant.

The more variety in shape and colours of the flowers in reason the better. A really representative group of Chrysanthemums should consist of Incurved, Japanese, Anemone, and Reflexed varieties. The colours should be carefully blended. Never place two plants of one colour, or nearly so, together; decided colours, such as Cullingfordi and Elaine, go well together. Experience teaches this much better than any amount of written instructions, as perhaps the varieties which might be named in many instances are not available. The two varieties named will serve as an example. Some societies require special arrangements, such as all Incurved to comprise one group, and Japanese another; but to my mind the four sections named are really necessary to make a thorough representative group of forms and colours combined. The number of Japanese plants would naturally predominate, as by their light and graceful forms they are particularly adapted to this kind of work. The Reflexed varieties would be the fewest in point of numbers, owing to their somewhat stiff appearance. The newer kinds of Anemone Japanese are specially suited to this purpose on account of the peculiar formation and arrangement of the florets of some of the varieties.—E. MOLYNEUX.

#### MASDEVALLIA POLYSTICTA.

THOUGH less showy than Masdevallias of the Harryana and Linden types, *M. polysticta* is worth a place in any collection, as it is one of the most floriferous of the small-flowered species. The sepals are lilac-tinted or nearly white, freely dotted with purple, the tails filiform and much darker than the other portion of the sepals. The flowers are borne in racemes of six to eight or more, as shown in the woodcut (fig. 68), which was prepared from specimens kindly furnished by F. A. Philbrick, Esq., Q.C., Bickley, where the plant is an especial favourite. The two lower sepals are usually slightly contracted in the centre and not so regularly ovate as in the figure.

*M. polysticta* is a native of Northern Peru, and was introduced thence in 1874 by M. Roezl with *M. melanopus* and others. It succeeds well in a cool house with *Odontoglossums*.

#### HORTICULTURAL SHOWS.

THE following are the dates of the principal Shows to be held during May and June this year. The Rose Shows are given in another column. The great event of the season will no doubt be the provincial Show of the Royal Horticultural Society at Liverpool at the end of June.

##### MAY.

- 19th.—Royal Botanic Society, Regent's Park, Summer Show.
- 21st and 22nd.—Crystal Palace, Summer Show.
- 25th.—Royal Horticultural Society Committee meetings and Exhibition of Pot Roses, Azaleas, &c

##### JUNE.

- 8th.—Royal Horticultural Society Committee meetings; Orchid Exhibition.
- 9th.—Royal Botanic Society second Summer Show.
- 11th to 18th.—Manchester National Horticultural Exhibition, Old Trafford.
- 22nd.—Royal Horticultural Society Committee meetings and Pelargonium Show.
- 23rd and 25th.—York Floral Fête.
- 29th to July 5th.—Royal Horticultural Society Provincial Show at Liverpool.

30th.—Croydon Horticultural Show.

30th.—Royal Botanic Society's Evening Fête.

#### VIOLETS.

IN many parts of the country Violets do not grow wild. Where they do the competition for the flowers is such that it is difficult to get two or three. Very few people would think that they could have too many sweet Violets about their grounds if they could be had without interfering with the other flowers. Have such keen lovers of Violets observed that wild Violets inhabit hedgebanks, where they have shade from summer heat, and are protected in winter with snow? Nothing else can do it so effectively, and it gathers soonest, and continues long in such places. Violets do best where they have to compete with other plants for soil,

Fig. 68.—*Masdevallia polysticta*.

and where they cannot grow thick and rank, but have to creep about to look for a vacant spot amongst the shelter of taller vegetation.

Every country garden has many as yet unappropriated places. Orchard banks, corners under deciduous trees, under hedges, such as Thorn, &c., besides screens of an evergreen description, such as Privet, Holly, &c.; alongside of Filbert bushes, behind walls where Nettles and other rank weeds grow, amongst shrubs, near rubbish heaps, in any waste ground that can be found in copse or woodland, are suitable places for Violets. Unsuitable are heaps of rubble, gravel, and rock; hollows so wet as to be a morass or bog; deserts beneath trees excluding light and rain; and soil so pre-occupied with roots as to be dry as dust. Spring is the time to plant the Violets in the garden as soon as the flowering is over. Water until established, and keep them free from weeds. Let as many runners grow as will. Mulch in autumn or early winter with a little leaf soil or other partially decayed material, and let things have their own way another year. Healthy, not gross plants, make the most of the soil and position in which they are placed.

September, or as soon after as the ground selected is thoroughly moist, is the time to replant. Loosen the places with a fork to afford a free-

rooting medium and the refreshing influences of rain and air. Clear away the rubbish, and remove the roots of any coarse weeds such as Docks, Hemlock, Nettles, &c. Lift the plants carefully, preserving as much root as possible, and divide into as many parts as there are crowns with roots. Set the plants 9 to 12 inches apart, or wider, as plants are available, only in increasing the space, the labour of clearing for planting, and the after attention, as well as gathering the flowers, is proportionately increased with the area. Press the soil gently about the roots, and the autumnal rains will settle it about them perfectly. By spring they will be established—rooted and rooting—prepared to take and keep their place amongst the inevitable accompaniment of vegetation. Never plant Violets in the woodland in spring. It answers to do so in the garden, but not here. Summer is upon the plants before they have well got root-hold; the most they can do is to maintain existence among the contending vegetation; the plants grow but little, flowers are sought in vain—a year is lost.

As the weeds will to some extent be subdued by clearing and loosening the soil for, and at planting, little if anything will be required the first season. The plants are the better for some protecting or fostering vegetation, albeit a coarse rank growth of weeds should be kept under by pulling up some of it, and repeated a few times through the summer, particularly the early part, will be all the attention required. During the summer accompanying vegetation is of value in screening the plants from scorching sun. In September enough of the ranker weeds should be cleared away to admit light and air. A slight top-dressing of refuse, as the *débris* of the potting bench, rubbish heaps, leaf soil, or well-rotted manure, is beneficial. In this way Violets continue for years little lessened in vigour or floriferousness. Spare plants, when fresh beds are made in gardens, can have fresh places looked out for them, by which means there will always be abundance of Violets in spring.

#### VARIETIES FOR SEMI-WILDNESSES.

*Viola odorata*.—Wild Sweet Violet, inhabitant of our hedgerows, known to everyone.

*Viola odorata*, var.—Flowers grey. Local in distribution; prevailing most on the oolitic formations.

*Viola odorata*, var. *alba*.—Flowers white. Though common in some localities its distribution is not nearly so wide or general as the species, and though found plentifully in some parts, it is more likely they are acclimatised than natural. In the north, wild white Violets are rare, and many places, even in the south, where they are found, is eminently suggestive of their being introduced. Albiflora and some others are only forms of this.

*Viola odorata rubra*.—Flowers red or pink; free and distinct.

*Viola odorata suavis* (Russian).—Leaves more glaucous or less hairy than *V. odorata*, more erect, and stouter in texture; runners plentiful, soon becoming thickly interwoven. Flowers blue, one-third larger than the wild Violet. Crimean, Scotch, London, floribunda, are only slightly varied forms of this remarkably free-growing, profuse flowering, and very sweet Violet.

*Viola odorata suavis superba* (Russian Superb).—Larger in all its parts than the type. Flowers purple, occasionally rosy purple.

*Viola odorata suavis alba* (White Russian).—Differing little from the type, except that the plant is less free in growth and not quite so hardy, and in the flowers being white.

*Viola odorata argenteaeflora*.—A distinct variety, raised by Mr. G. Lee, evidently a cross between the English and Russian forms of Violet. Foliage like the wild Violet, larger, and quite as hairy; flowers nearly twice the size of the common Violet, white or grey, suffused with rosy purple; spurs purple; footstalks long and wiry; produced over a longer period than any other Violet, but most abundantly in spring, very beautiful, and deliciously fragrant. Remarkably free in growth, hardy in constitution, and giving its flowers nearly all the year round, it is a valuable acquisition. Through the resemblance of the flowers to the wild Violet in form it is much appreciated by the æsthetic.—*VIOLA*.

#### GARDENERS AND PREMIUMS.

YOUR correspondent "Observer," at page 353, is inclined to find fault with me for not mentioning names in my communication on the above. Such a step I considered would have been extremely indiscreet, and I think I acted as ninety-nine out of every hundred would have done, and exactly as "Observer" does in his narrative of a similar case, which is such that no one need be ashamed to have his name associated with. I, on the other hand, had only what appeared to me a series of complaints to present to your readers as related to me by an aggrieved person, and whose statements might be exaggerated. I thought the mention of the case in your columns would test the truth or falsity of the matter. The gardener in question can give the other side, as your correspondent "Thinker" remarks, and by whose counsel copies of the Journal have been forwarded. If he can, and thinks fit, prove the rumours to be unfounded, no one will be better pleased than the writer. This will be a more agreeable proceeding than giving his name in the first instance, as suggested by "Observer" without previous intimation.

Referring to "Observer's" letter, I notice that in the "charitable" case he alludes to there are one or two rather curious features. After his friend received the letter from the young man anent flowers and hours of labour, he engaged him, yet there are always plenty of young men to select from, though perhaps not with £5 in their pockets. It is also stated by "Observer" that the young man was incapable of performing the duties he was engaged for. Here one is curious to know what efforts

were made by his paid teacher to instruct him? And if he was supposed to be competent what was the premium for? I also note that he was kept on after his incapacity had been discovered, and considerable forbearance seems to have been exhibited towards him by his chief, but whether actuated by philanthropic motives solely it does not appear clear. There is something peculiar about the £5 having to be paid the first year. Will "Observer" tell us how many young gardeners that enter pass the second year in that establishment?—W. P. R.

AFTER reading the article brought before us by "W. P. R." on page 342, and again by "Observer" on page 353, I was struck with a resemblance to a similar case, and have taken a little trouble in sifting out a few facts connected with the same, and I hope you will not close your columns upon this case until it has had a fair hearing. Since the last issue of the Journal, I have had an interview with a young man, who is, I assume, the same as referred to by "Observer," and from what I have gleaned of both sides of the question—namely, from "Observer" on the one hand and the young man on the other, I am satisfied there is at least good reason for disquietude and inquiry. Like "Thinker," I do not agree to found a charge on something that is "understood;" but let us examine the case. A young man was engaged, and did enter upon his duties upon terms pretty much the same as stated by "Observer." But the order of dismissal was different. The young man was employed in the earl's garden ten weeks (not several months), the wages 15s. per week, both, &c. During the first week's service the young man was asked if he was prepared to pay the £5 premium, and he replied he was not at present. Nothing more was said about the premium; but on the third week, and fortnightly after that, various sums were deducted from his wages to the amount of 27s. during the ten weeks' service.

Now let us look for a moment at the rate of deduction as admitted on page 354 by "Observer"—24s. This for a period taken from the young man's diary, and proved by the dates of entering and leaving, is ten weeks and four days. The custom, not the agreement, being for the £5 to be paid during the first year the amount deducted is at the rate of £6; but the actual amount deducted was 27s., making the sum of something over £7 for a year if taken at the same rate throughout. I am thankful to be able to say to the credit of head gardeners and the comfort of young gardeners that I know of no other similar cases.

"Observer's" defence of too much dress may be passed. The charge of not "turning out" and ignoring the foreman's authority is disputed, and the foreman knows whether it is true or not. As to using gloves in a stokehole, in three excellent gardening establishments where I have lived gloves have been, and are, provided for the young men to stoke in if they chose to put them on, and in many other places known to me. I now content myself by saying if the earl's gardener does not return the money deducted the noble owner of the estate will be strongly petitioned on the subject.—ANOTHER OBSERVER.

[We think it right to say that this letter has been sent to us by a head gardener of respectability personally known to us, as is "Observer," who is equally entitled to veracity. Both state what they believe to be true; but that is not a sufficient justification for our publishing the name of the noble earl's gardener referred to in the present stage of this discussion.]

#### MIGNONETTE IN POTS.

FEW plants in flower give greater pleasure during the dull months of the year than Mignonette; in fact, a succession of plants is indispensable in many establishments from the time they are cut off by frost in autumn until the flowers can be gathered outside in early summer. The supply, therefore, to meet this demand is, for the greater portion of the year, dependent upon plants grown in pots and others specially prepared in cold frames.

Mignonette is easily cultivated if a few simple rules are observed, but well-grown examples in private establishments are the exception and not the rule. Generally, a few brown, woody, miserable examples are to be seen, instead of healthy luxuriant plants bearing large well-developed spikes. A supply of healthy plants for room-decoration from November until May, and for cutting until we can gather outside, is one of the requisites of this establishment; therefore, the system of cultivation pursued may prove helpful to beginners.

For flowering on standard and pyramidal trellises from November through the winter, seed should be sown at once and again in about a month for spring flowering. If cool greenhouse treatment throughout only can be given sow the seed now, for the plants will not grow so rapidly as those raised in heat. The best variety for this purpose is undoubtedly Miles' Hybrid Spiral. The seed can be obtained moderately true, but some small-foliaged varieties are almost certain to appear, which should be thrown away directly they are observed, for they will never give satisfaction. It is, therefore, necessary, when bought seed has to be relied upon, to sow more than are required to be grown on for a time until the best can be distinguished. The most reliable plan is to select for seed-bearing from the first year's plant a good strong grower, free brancher, and one that produces large fragrant spikes. Some are much more fragrant than others, and those possessing only a faint perfume in spring will be almost scentless during the winter. Pots 3 inches in diameter should be prepared by placing a few small crocks at the base, and then fill with a compost of loam, one-third leaf mould, one-seventh of decayed manure, and a little sand, the compost being pressed firmly into the pots, which must be perfectly clean and dry. The seeds, three or four in number, should be sown in the centre of each, and then lightly covered with the same

compost. Place the pots where a night temperature of 60° can be maintained, and where they can be kept gently moist and shaded from the sun until germination takes place. Those only having cool structures should follow the details that will be given, for the only difference in the end will be that the seed is longer germinating, and the plants will be longer before they are ready for their largest pots. At one time we sowed the seed in thumb pots, but have discontinued doing so, because they were difficult to keep moist, and the plants require repotting before they attained much strength. We advise intending cultivators not to use smaller pots than those named.

When the young plants are large enough to handle, thin them to two or three, until it is certain they will not go off, when the most promising plant only should be left when intended to train them upon standard trellises. When good-sized pyramids, or even large bushes are required, three or four plants may be left in preference to one. For this purpose the seed may be sown evenly over the surface of the soil instead of the centre, so that the young plants left will not crowd one another. Those required for standards must have a small upright stake as soon as they are 2 inches high, by which time they will be ready for transferring into larger pots. This time 5 and 6-inch pots will be the most suitable. By the time they are about 1 foot high they will be ready for potting in their largest size. During the time they are growing upright remove all lateral growths as they appear in the axils of the leaves until sufficient length for the stem of the standard has been attained. By the time the plants are established in the 5 and 6-inch, they must be gradually hardened to cooler treatment until artificial heat can be dispensed with. Care must be taken in lowering the temperature that the plants are not checked, or they will become woody, and when this takes place they never make free growth and luxuriant specimens afterwards. Those required for pyramids should, until they are placed in their flowering pots, be trained upright to as many stakes as there are plants in the pot. The central one must have the lateral growths removed from the axils of the leaves until it is about 9 inches in length, when it may be stopped and allowed to branch. Three shoots for training towards the edge of the trellis will be ample, while a fourth should be trained upright. When bushes are required the plants may be stopped when they are about 4 inches high, and this must be practised from time to time when the same amount of growth has been made until a sufficient number of shoots has been formed. The shoots as they are made must be supported with slender stakes; if not, they are very liable to be broken. For the earliest-sown plants, whether standards, pyramids, or bushes, 10-inch pots should be employed. For later-sown plants 8 and 9-inch pots will do if the smallest trellises are selected.

Great care must be taken when potting the plants that they are not checked in the operation. The roots are easily broken, therefore the pots used should be perfectly clean, and the crocks used for drainage should be moderately small, so that they can be easily removed from amongst the roots. From the time the seed is sown they must never suffer by insufficient root room until they are placed in their flowering pots, or they will be ruined. Directly plenty of active roots have reached the sides of the pot the plants must be shifted into larger. When given their last shift they certainly appear as if they were overpotted, for the pots are certainly large in proportion to the size of the plants, but this must be the case if success is to be attained. The flowering pots must be liberally drained, and the compost pressed moderately firm into them, not as hard as it is possible to ram it, for we have proved that this course is a mistake, and often proves detrimental to the plants. The compost should be the same as advised for the seed pots with the addition of one 5-inch potful of soot and the same quantity of bonemeal to each barrowful of soil.

The pyramidal trellises may be home-made, and the plants trained to them as soon as they are established in their flowering pots. A round hoop should be made of moderately strong wire, 18 or 20 inches in diameter, which should be secured at the base by two flat stakes placed across each other. These should be held in position by a hoop of copper wire just beneath the rim of the pot. If the cross stakes are secured to this they will support the outer rim intended for the base of the trellis. A moderately strong central stake, 20 inches or 2 feet in length, should be placed in the centre of each pot to carry the six or eight strings, copper wire being the best and most durable, that will be stretched across it from the hoop. Small nicks may be cut into the top of the stake to carry them until they are secured on both sides to the hoop, when the whole may be bound firmly at the top to the stake with thin copper wire. Standards can be purchased ready made, or may be made to order. A very serviceable size is to have the legs above the soil 1 foot or 14 inches in length, with heads about 18 inches in diameter moderately well rounded. We have some with stems over 2 feet in length, but they are not so effective, and this year we are discarding the whole for shorter stems, which displays the head to greater advantage when the plants are used for room-decoration, and have to stand singly in a vase on a small table or other similar position; in fact for all kinds of furnishing purposes those with the shorter stems are the most desirable. Those grown in 8 and 9-inch pots have trellises with slightly smaller heads; in fact these do not exceed 15 inches, the legs being the same as the others. Most of the purchased standard trellises have a quantity of close wirework in the centre, unless otherwise ordered, which certainly makes the trellis much neater in appearance when passed from the wireworkers' hands than the one I intend to recommend. This close wirework, although it looks well, proves a nuisance when the plants have first to be placed on them.—N. G.

(To be continued.)

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Major F. Mason in the chair, the following candidates were unanimously elected Fellows—viz., Edward Crofton, Robert A. Dalyell, C.S.I., Charles Fielding, O. T. Hodges, Henry Holmes, William Brittain Jones, Miss C. S. Morison, John C. Sanderson, John Scott, jun., S. J. Smith, Robert George Veasey, Mrs. William Wright. In addition to the above (69) corresponding members were elected.

— RECENT WEATHER CHANGES have been somewhat remarkable. Last Friday the thermometer registered 78° in the shade at Greenwich Observatory and 131° in the sun; four days afterwards we read of snow in Cumberland. The mean temperature of the air last week at Greenwich was 55.2°, or 5.5° above the average of the corresponding week of the twenty years ending 1868. The weather yesterday (Wednesday) was cold and showery in London.

— SPRING STRAWBERRIES.—Mr. J. Muir writes:—"Up to this time we have had three sorts in fruit. The first to ripen was Black Prince, the next Keens' Seedling, and the third James Veitch. Of the three Black Prince is our favourite, as it fruits more freely than any of them, is of a good size, and peculiarly pleasing in flavour. Keens' Seedling is also prolific and fine in flavour, but not so rich in colour. James Veitch is the most handsome, producing fruit of great size, but very few of them compared with the others, and it is not a sort I would grow for profit."

— AN Essex correspondent sends us a stem of a TULIP bearing THREE FLOWERS, which is evidently due to fasciation, the flower stalks being separate at the upper part and two of them furnished with leaves. At the lower portion the stems are consolidated into one. A combination of two flowers in this way is sometimes seen, but the fasciation of three is seldom seen.

— THE preliminary reports of the HORTICULTURAL CONGRESS AT PARIS this year (May 11th-16th) have just reached us. They comprise contributions by Mr. A. F. Barron, and M. M. Hediard, Godefroy-Lebeuf, Georges Bellair, Thierry, E. Roze, Van den Heede, A. Bleu, J. Dybowski, A. Changueraud, Charles de Bosschere, and several others on a variety of subjects to be submitted to the Congress for discussion.

— MESSRS. J. CARTER & Co have now a good display of CINERARIAS AT THEIR FOREST HILL NURSERIES, considerable space being devoted to these popular plants for yielding seed. For several years great care has been exercised in improving the strain of Cinerarias, and numbers of very bright colours have now been obtained, the blooms also of good size and substance. All who have greenhouses or conservatories know the value of these plants quite well, their richly coloured flowers being most welcome when the scarcity of other floral attractions is rather too marked.

— "B. D." writes:—"I have ODONTOGLOSSUM ROSSII producing a large pod of seed. O. Pescatorei, O. tripudians, and the Dendrobium nobile, with numerous other plants, were in bloom in the same house at the same time as O. Rossii. I think O. tripudians was gone too far to give pollen. Consequently of the large variety of flowers on fine days bees were attracted into the house in large numbers, so I conclude the bees must have fertilised the flower in question. Several gardeners have seen the plant, but they are like myself, do not know if O. Rossii often yields seed in this country. I shall be greatly obliged if some reader of the Journal could inform me whether it is a general occurrence for O. Rossii to yield seed so freely, also if it is worth trying to ripen; if so, the best treatment that will suit the plant in order to get the seed properly ripened."

— "D., Deal," writes:—"Woe is me! Shall I be prosecuted for libel, or will the Mayor write to *The Times* and show me up as a slanderer? I wrote on MR. GEO. MOUNT'S NURSERY, 'a city so abounding in churches,' which somehow or other got transformed into 'a city so abounding in smoke.' My poor dear Canterbury! than which there are fewer places that have so strong a hold on my affections. To say it abounded in smoke when it is guiltless, I believe, of even one factory! There are

one or two other mistakes. I suppose I do not write in that copperplate character I used to, or else another compositor has arisen who does not know my caligraphy."

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 19th inst. at 7 P.M., the following papers will be read:—"The Severe Weather of the Past Winter, 1885-6," by Charles Harding, F.R.Met.Soc. "Description of an Altazimuth Anemometer for recording the vertical angle as well as the horizontal direction and force of the Wind," by Louis M. Casella. "Earth Temperatures, 1881-1885," by William Marriott, F.R.Met.Soc. "Note on the After-Glows of 1883-1884," by Arthur W. Clayden, M.A., F.R.Met.Soc.

— AN exhaustive article upon the ORIGIN OF THE POTATO is given in the issue of *Nature* for May 6th, in which the references are given to a number of early writers who mentioned the plant, and some interesting quotations from various sources to illustrate the subject. The author, however, states that the "whole question is by no means yet worked out," but some of his most important conclusions appear to be that the Potato "was known in several hotanic gardens in Europe before the time of Gerard's first catalogue;" and "that Gerard in some way received information from or through Clusius that the plant was first discovered in America; America here evidently means South America."

— A CORRESPONDENT of the *Glasgow Evening News* says that "having occasion to call at Kincardine School-house, Blair Drummond, recently, he enjoyed a great treat in an extensive display of the choicest stage AURICULAS in bloom. Those unacquainted with these exquisite flowers have no idea of their rare and varied beauty, and growers of them would be even more delighted with the sight of their favorites so well grown and bloomed, as this fine collection is now about its best." We happen to have before us a number of flowers of seedling Alpines raised by Mr. Kilgour, whose collection is above referred to, and without saying they are worthy of names as distinct varieties, they are still by far the best unnamed seedlings we have seen this year, and most if not all of them are worthy of preservation and culture."

— OZONE FROM FLOWERS.—It is said that a "professor at Pavia has discovered that ozone is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinths, Mignonette, Heliotrope, Lemon, Mint, Lavender, Narcissus, Cherry Laurel, and the like all throw off ozone largely on exposure to the sun's rays. So powerful is this great atmospheric purifier, that it is the belief of chemists that whole districts can be redeemed from the deadly malaria which infests them by simply covering them with aromatic vegetation. The hearing of this upon flower culture in our large cities is also very important. Experiments have proved that the air of cities contains less ozone than that of the surrounding country, and the thickly inhabited parts of cities less than the more sparsely built, or than the parks and open squares. Plants and flowers and green trees can alone restore the balance."

— "W. I." states that "The best CINERARIAS I have yet seen in a private garden are now on view in the conservatory adjoining the residence of A. R. Trotman, Esq., The Elms, Frome. They form a grand bank along one side of the house, the front row standing on the tessellated floor, and as no bright sunshine ever reaches them, the plants also being perfectly clean, the display will most probably last till near the end of May. They are grown in pots ranging in size from 7-inch to 10-inch, and every plant will bear close inspection. The strain, it ought to be noted, is Messrs. Cannell's, and contains a good percentage of extra well formed flowers in various colours, including a remarkably fine white, which may be said to be the cream of the collection. This is no chance success, as Mr. Trotman's gardener never fails to grow them well, and one of his secrets—an open one, however—is cleanliness. At no time are green fly allowed to gain a footing, and little or no fire heat is ever given beyond what may be necessary to protect them from severe frosts when coming into bloom. Every plant is given plenty of room from the first, and the Cinerarias are never "jumbled" up among a miscellaneous collection of plants. They pay well for liberal treatment, as all who have seen Mr. Trotman's collection will readily admit."

#### LIQUID MANURE FOR ORCHIDS.

ALTHOUGH many of the epiphytal Orchids may not be benefited by the direct use of liquid manure I find that by syringing between the pots

and damping any dry surfaces under the stages, &c., two or three times a week, an improvement takes place in the foliage, and the roots hanging from the pots and baskets evidently enjoy the application, and carry the constituents of the manure to other parts of the plants. Aerides, Vandas, Cattleyas, Masdevallias, Odontoglossums, and Phalanopsis all like the ammonia arising from it. But little difference is noticed between the use of Clay's Fertiliser or the liquid drained from the cowsheds and stables, and which is diluted to the same strength as for Pelargoniums usually. Most of the terrestrial Orchids receive much nourishment from its use in the ordinary way from the watering-pot. Some of the Cymbidiums, Cypripediums, Cyrtopodiums, Mormodes, and Zygopetalums may be kept in the same pots for years and the roots remain in good condition, as they receive such food from the manure that the roots become so matted together it would be rather difficult to remove any of the old compost without injury to the roots. Anguloas, Arpophyllums, Lælias, Grammatophyllum Ellisii, Houlettias, Lycastes, Phaias, Sobralias, and Trichosma do well with the same treatment.—G. W. C.

#### EUPATORIUMS.

No doubt many gardeners will agree with me when I recommend the Eupatorium to be cultivated for winter work. *E. odoratum* and riparium we find most useful for ordinary decorative purposes, and if the cuttings are taken off and inserted singly in thumb pots, placing them in a gentle heat, they will soon become rooted and be ready for their final shift. The sizes most useful for ordinary purposes are 48 and 32's, but if large specimens are required three or four plants may be placed in a 16, or any other size the cultivator may require.

Eupatoriums delight in a rich soil; loam and cowdung in equal parts, with a good dash of sharp sand to keep it porous will be found to answer well. After they have become established air may be admitted freely to prevent their becoming weak. Stopping is necessary once during the summer to make them break well from the bottom; after the growth is almost completed they may be trained into the shape required. With small plants we find it best to insert four stakes round the edge of the pots, training the shoots down as to form flat heads after placing them near the glass to prevent their being drawn. Copious supplies of water will be necessary at all seasons, and liquid manure will be found very beneficial when the plants are making their growth. They last moderately well in rooms, and the flowers are very useful for using in a cut state, its white flowers and bright shining foliage making a good contrast with other plants of the season, and when given a fair trial I think professional or amateur gardeners will not regret the trouble bestowed upon them.—G. P.

#### ORANGE CULTURE IN FLORIDA.

(Continued from page 364.)

THE more thorough the cultivation the better the results. The ground should be kept clear of weeds and grass. It should be planted with some kind of crop which will grow rapidly and speedily cover the land, affording protection from the sun. If the planter does not wish to take anything from the soil it can be planted with cow peas. Several crops of these may be grown and turned under during the year, and add nitrogen—the base of ammonia—to the soil. Should the planter wish to gather crops from the soil while the Orange trees are growing, to lessen the expense or pay for the cost of cultivation, he can plant vegetables, Cucumbers, Cabbage, Tomatoes, Beans, &c. But if at the same time he would benefit and not damage the ground for Oranges, he must be careful to add yearly more fertility to the soil than has been taken from it by the crops removed.

All material containing either nitrogen, phosphoric acid, or potash, provided no one or two of these be given in excess, is beneficial. These materials enter into the composition of all plants in a certain ratio, governed by the particular species. The Orange tree has its own formula. The intelligent planter should ascertain as nearly as he can what this formula is, and then as nearly as possible what his soil contains, and then supply the deficiency. When the trees are young they need more of ammoniated manures; when fruiting they need more of phosphoric acid and potash. Stable manure is a standard. It should be well rotted before it is applied. It is better to compost it with muck, leaves, grass, or any other vegetable matter. When vegetable matter, with or without muck, can be obtained it is well to compost with bone, and some one of the salts of potash. When muck cannot be obtained sulphate of lime should be added to retain the ammonia. Many of the commercial manures are good, and can be used with great profit. Where the planter wishes to combine his own fertilisers the following is an excellent formula:—Equal parts of Cotton seed meal, ground bone, sulphate of lime, and sulphate of potash. Vegetable mould or muck can be substituted for sulphate of lime. When these substitutes are used they should equal in bulk all the rest of the material. The pile should be frequently turned to insure uniform combination.

The following directions as to gathering and packing are suggested:—The fruit should be clipped with a stem as short as possible from the tree; handled carefully to prevent any bruising, and cured before packing. The first handling of the fruit is most important, for then it is more easily bruised than later. Any Orange falling on the ground should be rejected, as it is likely to have been damaged by the fall. If the weather is warm and damp prior to packing the fruit it should be subjected to fumes of sulphur to destroy any germs of fungi. With proper care in handling and curing the Orange I doubt not it can be preserved for months after it is gathered, and so extend the time of marketing throughout the year.

Florida has never yet produced fruit enough to force a fair experiment in this direction. Her crop, so far, has been annually consumed by the beginning of summer. The foreign Oranges that are sold in many of the northern markets during the summer as "Florida Oranges" are but the continuance of frauds begun in the fall or winter upon the credit of the superior quality of the Florida Oranges. If anyone wishes to detect this fraud he has but to look through a box of Oranges sold as "Florida" during summer, and see if he can find a russet-brown Orange, the peculiar mark of Florida. The russets keep longer, and are really sweeter than any of our Oranges; but neither they nor any other Florida Oranges are to be found, thus far, upon the market during summer. I should make one exception. Occasionally a few of a second crop are sold in summer. But so far, the people of Florida will pay a higher price for such Oranges than can be obtained outside of the State.

The fruit is usually wrapped in tissue paper, and packed in boxes of standard size. Transportation has greatly improved within the last few years. The business has become so great as to occasion many competing lines. But transportation is not yet what it should be to insure the best results. Freights are becoming reasonable, but unnecessary delays often occur, and the boxes are often handled like the luggage of the traveller, as though to make a short search for explosives within. Shippers should select those lines which handle with most care.

Mr. A. A. Robinson, Commissioner of State Bureau of Immigration, has also given some valuable hints on this subject as follows:—

The Orange can be more extensively and profitably grown in Florida than in any other State of the Union. Louisiana, Texas, and California will in time compete with us in the production of this popular fruit, but from advantages we enjoy in certain peculiarities of climate, soil, and seasons, it is more than likely that Florida will ever retain a superiority over any other section of the country in its production.

The history of Orange-growing in Florida as an industry is very recent. True it is that our primeval forests abound, in some localities, in native wild groves. With the first settlement of St. Augustine by the Spaniards, it is probable that the Orange was planted and cultivated with success. During the period of American occupation, from the cession in 1819-21 up to the close of the Civil War in 1865, many Floridians had planted and matured extensive groves, prominent among which was the renowned Dummit Grove on Indian River, together with others of less size at St. Augustine, and at several points along the St. John's River and at Tampa Bay. Still these *ante-bellum* groves were merely among the embellishments of home surroundings with a few wealthy proprietors, as fishponds or other ornamental features sometimes are upon the premises of northern men of wealth; but nowhere in Florida was Orange-growing regarded as a business to be pursued solely for profit.

After the late war, the winter climate of Florida was sought by hundreds of northern people in pursuit of health. The beauty of the rich golden fruit and its dark-green foliage attracted the eye, and, as many of these visitors bought and improved homes along the banks of the St. John's and other accessible points, they began the propagation of the Orange. Gradually the facilities for its culture and the wonderful profitability of the business became apparent, and induced investments in small tracts for the purpose. Year after year, as at various points additional trees and young plantings came into bearing, the great superiority of the Florida fruit over any other made itself felt in the north. The demand for "Florida Oranges" began to grow, prices advanced, improved methods of propagating, by budding, pruning, and fertilising obtained; year by year the demand and supply continued to increase. Soon, choice locations adapted to the culture of the fruit began enhancing in value—lots that for fifty years had remained vacant at 1 dol. 25 cents. per acre, were found to command and readily bring 50 dols. to 100 dols. per acre. And so the enormous profitability of this industry became noised abroad, and the "Orange fever" was fairly established, and not without good cause; for however extravagantly the subject has in many instances been treated by some writers, not always without selfish purposes, in inducing sale and settlement of lands, there is no shadow of doubt as to the really sure and safe ground for the investment of untold thousands of dollars in making Orange groves.

One thousand dollars per acre per annum has time and again been realised from this business. Indeed, double that amount per acre has been frequently made; and with proper culture and fertilisation, where the latter is needed, 1000 dols. per acre is an available crop. Like all excellent things, Orange culture has many and serious obstacles to its successful accomplishment. Being a new business, there is not a vast amount of experience to govern and direct the beginner. Almost as many different theories exist as to the most improved methods of culture as there are men engaged in it.

The natural enemies of the tree and fruit are numerous, and not very well understood. An entomologist recently sent from the Bureau at Washington reports having discovered no less than thirty-five different insects that are in a greater or less degree damaging to the Orange. Judicious selection of locality as well as location for groves are most important matters. The selection of stocks, buds, seeds, and the best methods of planting, protecting and cultivating, are all material factors of success. Frosts, droughts, gales, and other casualties are to be considered, and time is largely of the essence of the undertaking. We believe, from experience thus far, that, on an average, it requires twelve or fifteen years to make an Orange grove very profitable from the time of planting. True it is that in some, perhaps many instances, where the environments were in all respects most favourable, much better results have been obtained.

While Commissioner of Immigration the writer has had numerous

inquiries made of him from all parts of the country as to the advisability of "poor men" coming to Florida for the purpose of engaging in Orange culture. He is frequently asked: "How much capital is required to enable a man to engage in growing Oranges?" "Can a man with very moderate means put out an Orange grove and make a support off the land while the trees are growing?" &c. These, like many others of analogous character, are very pertinent inquiries, but quite beyond most persons' capacity to answer. The amount of capital required depends, of course, on the extent to which the enterprise is pursued. The cost of land, trees, labour, and support are all involved, and these vary as to localities and what might be thought a support by different people.

It has been customary heretofore, by writers on this subject, to submit estimates of the cost of these several items, appended to which frequently occurs such an entry as "value of five acres in bearing trees, seven years old, dol.—," &c. We will attempt no such table. We have been quite unable to reconcile the great discrepancies of experimenters in their estimates of bringing a grove into bearing; too much so, at any rate, to be able to digest therefrom reliable data for the guidance of others.

We believe, however, that Orange-growing, while, of course, it can be engaged in at a decided advantage by those who have means to conduct it on a cash basis and be independent of support until such time as the grove is an assured success, does not, nevertheless, present any insurmountable features to "poor men"—by which term we mean, in this instance, men without ready money, and dependent upon their own labour for support. Indeed, in the knowledge of the writer, many of the most successful, and, to-day, independent Orange proprietors in Florida, began the business with no other capital than their own labour.

But, for fear of misleading minds prone to overlooking the details when so dazzling a prospect is offered them of converting in few years acres of 1 dollar 25 cents. land into bonanzas yielding princely incomes, we caution them that there is a long hungry gap between raw Pine woods and groves of bearing Orange trees. It takes many hard licks, plenty of pluck, assured health, good luck, and favourable auspices. To all of which a large family, bad health, indolence, inexperience, or accident are possible drawbacks.

It has been urged that the profits of Orange-growing would directly attract so many to the business as to overstock the market and break it down, but a little reflection will dissipate such fears. Apples sell as readily now, and at as good prices, as they did forty years ago, and yet there are millions of acres suitable to growing Apples where there are hundreds suitable to growing Oranges, and there are millions of Apples now on the market where there used to be one. If the Apple market cannot be so overstocked as to break it down, much less can the market for Oranges. The consumption of the Orange within the United States is put down at 600,000,000 per annum. A little above 50,000,000 of that supply is furnished at home; the remainder, as shown at the custom-houses, is made up of receipts from abroad.\* We furnish about one-twelfth of the supply, while foreign sources furnish the other eleven-twelfths. The ease by which we can effectually occupy the market when our supply is sufficiently enlarged is shown in the fact that the foreign fruit is frequently sold in the market as "Florida" fruit to procure for it a more ready sale. Ours is of a better quality and richer flavour, and the foreign article finds a market among us only because the home supply fails to meet the demand, and this demand is increasing almost as rapidly as Orange trees in Florida are multiplying.

### THE ROYAL HORTICULTURAL SOCIETY.

The present condition of the Royal Horticultural Society, and the efforts which are being made to improve its position in the eyes of the horticultural world, are of great interest to gardeners. It is too evident from the facts given in the article on page 327, relative to the founding and after career of the Society, that the name has all along been a misnomer, and an institution which should have had for its principal object of existence the welfare, not only of horticulture, but also of the gardening community, has had its funds diverted into a channel altogether alien to the real interests of a horticultural society. The present Society has, in fact, ever since its unfortunate alliance with the Commissioners in 1861, been gradually developing itself into a competitive rival with the Crystal Palace and Rosherville—a mere place of fashionable resort. If a census of the present Fellows were taken, it would be found that three-fourths of them joined the Society, not for their love of or sympathy with the cause of horticulture, but for the attractions and convenience of a select local promenade. The horticultural section should throw off the Kensingtonian yoke as soon as possible, and endeavour to reconstruct the Society upon a wider and firmer basis elsewhere. The Society will thus secure a far greater amount of support, not only from a class of men who are daily manifesting a great interest in the welfare of horticulture, but also from the great body of gardeners themselves than it has ever previously received.

When those who really have the interests of the Society at heart make up their minds to quit South Kensington altogether, and to reconstruct it elsewhere, we hope the claims of gardeners to have a voice in its management will not be overlooked, and that provision will be made for allowing the fraternity the opportunity of becoming at least Associates, if not Fellows, at a reduced annual premium—viz., half a guinea. Of course

\* This was in 1881. In 1884 the shipments exceeded 150,000,000.

the privileges would not have to be so great as for those who paid, say two guineas, but surely it would be conducive to the welfare of the Society to secure the co-operation of gardeners, numbers of whom would be glad to be associated with it on some such terms as suggested. Still more substantial help would be forthcoming from the rich classes of the mercantile community than is now given when the Society resumes its proper functions.

The difficulty appears to be in securing suitable premises to carry on the work of the Society in a central position. This, however, is a question of ways and means, a problem which is surely capable of solution. Some have suggested the Thames Embankment, others the neighbourhood of Regent's Park. No doubt a suitable place will be found if it is sought for by practical men. I should like to see the Society flourishing with the support of wealthy patrons of horticulture, the nursery trade, horticultural builders and gardeners. Let these several classes directly interested in horticulture combine, and we shall no doubt soon see the Royal Horticultural Society develop into an institution thoroughly representative of British horticulture; at least that is a dream not altogether hopeless of realisation by—A BRITISH GARDENER.

## THE HUNTINGDON NURSERIES.

(Continued from page 362.)

HARDY perennial, herbaceous, bulbous, and alpine plants are extensively cultivated, patches sufficiently large to exhibit the general effect of each being grown in addition to the usual sale plants in pots or otherwise. Those most remarkable at the time of my visit (the third week in April) were *Anemone stellata* fulgens, brilliant scarlet, a gem for cutting; *A. appennina*, blue and its white variety, which, with the Wood *Anemone* (*memorosa*), and its variety *lutea*, bright clear yellow, are fine for naturalising. In the mass they are simply charming. *Adonis vernalis*, large yellow flowers, is doing better than is usually seen. *Orobis vernus*, with its pretty pea-shaped flowers, rosy purple, about a foot high is effective; but far more telling is a species of *Henbane* (*Hyoscyamus physaloides*) with very dark metallic foliage, and Prussian blue, almost black flowers. In strong contrast with the last is *Symphitum officinale variegata*, its clear yellow variegation on its bold foliage being very effective. *Aubrietia græca*, sheets of purple, is one of the best, and *Doronicum austriacum*, with its large yellow flowers and bright green foliage, effective. *Pulmonaria paniculata alba variegata*, a mass of white flowers about 1 foot high. *Sanguinaria canadensis*, only a few inches high, and with snow-white flowers, lead up to the larger *Ranunculus amplexicaulis*, pure white. *Erythronium Dens-canis* and *var. alba* have remarkably pretty foliage; and not less interesting in foliage is the beautiful *Tulipa Greigi*. The yellow *Tulipa sylvestris* is also charming. It does well naturalised in woods; and *Triteleia uniflora* and *lilacina* are eligible for a similar purpose. *Fritillarias* in masses are most telling, the stately growth of the Crown Imperials, about a yard high, capped with flowers, being very beautiful. The best were *F. imperialis flava plena*, yellow; *F. imperialis monstrosa*, very large bells, red; *F. imperialis grandiflora*, very large heads of bloom as well as flowers, and bright in colour; *F. imperialis rubra plena*, double red, and *variegata*, pretty sulphur-edged variegation. Brighter in colour than most is *F. imperialis rubra*. *F. Meleagris*, bell-shaped drooping flowers, just showing its purple finely marked flowers, whilst the white variety *alba* were in flower. *F. pyrenaica* has pretty grassy foliage, and anon brown and yellow flowers. *F. persica*, having fine glaucous foliage and brown foliage later on. These *Fritillarias* are not so common in gardens as they deserve, and why it is difficult to understand, as they are only of moderate height (1 foot), and are so effective in early summer.

Daffodils are well represented by Sir Watkin, large in size, and beautiful in fringe and colour, tube golden yellow, perianth stout, broad, and pale primrose, very fine. Emperor is more striking, being of such great size and substance, the golden yellow trumpet and delicate primrose perianth rendering it very beautiful. Empress is very fine, indeed one of the noblest, golden-yellow trumpet and broad white perianth, finer even than *N. bicolor Horsfieldi*, which last well deserves the appellation of King of the Daffodils, and it certainly is one of the very finest, being so free and early. *N. obvallaris* (Tenby) is one of the freest, and *N. poeticus ornatus* deserves note as the earliest flowering of that section, and being so fine and sweet for cutting. Most of the now very numerous family of Daffodils are represented.

With a look at *Pæonies*, *Irises*, *Delphiniums*, *Potentillas*, *Pyrethrums*, *Phloxes*, &c., that will gladden later on, I came to some *Ivies*. Osborn's New Silver is a fine variegated form with medium-sized leaves; *Hedera Helix madeirensis variegata* also has medium-sized leaves and distinct variegation. Of the large-leaved *Irish* (*Hedera helix canariensis*) is far the best, *Hedera digitata* being very distinct, and *rhomboida variegata*, *maculata major*, *palmaria*, and *ovata* have all large or medium-sized foliage, the latter being the most close clinging of all *Ivies*. Of the small-leaved sorts *taurica* and *donerailensis* are the best; and of the somewhat larger or medium-sized leaved kinds *hybrida variegata*, *Crippsi*, *chrysocarpa* (yellow-berried), and *himalaica*. *Atro-purpurea* is a very neat free-growing kind, with purplish green foliage, very distinct; and *glomerata* has its leaves set thickly on both sides of the stem, which gives it a most singular appearance, even quaint and grotesque.

At the St. Neot's branch *Pelargoniums* for bedding are grown extensively, there being about 30,000, and as a criterion of their value for their particular purpose the number grown of each is suggestive. *Vesuvius* heads the list with 10,000, Henry Jacoby 4000, Master Christine 3000, Whites 3000, West Brighton Gem 2000, Bronze and Gold 5000. *Vesuvius* is far the most popular of scarlets, but West Brighton Gem is dwarfer, more compact growing, freer flowering, and is considered much the best scarlet bedding *Pelargonium*. The foliage is marked by a clear well-defined zone as in *Vesuvius*, and as proved in trial beds (all the kinds as sent out being subjected to this ordeal annually, with a view to an estimate of their merits and consequent selection of the best), is likely to supersede it. John Gibbons, with plain green leaf and somewhat strong habit, is the best of the taller kinds, the flowers being very large, fine form, and great substance. Master Christine holds its own as much the best pink, habit, floriferousness, and general usefulness

placing it first in its class. Henry Jacoby is far ahead of all the crimsons, it being so free and fine in form as to excel all others for bedding purposes, and as a pot plant, especially for winter flowering, is unrivalled. Its colour is so bright and shining as to render it particularly attractive and telling. Of Whites as a bedding White Perfection is considered the best. Of varieties for pots the best were Corsair, orange scarlet; David Thomson, crimson, white eye; Dr. Orton, deep crimson; The Shah, crimson scarlet; Hettie, rose madder; General Roberts, pale salmon; Mrs. Taylor, white, salmon centre; Acme, rosy salmon, edged white; Lady Sheffield, lilac pink; Sophie Birkin, salmon; White Clipper, and Niphetos, pure white, immense trusses, good for winter flowering.

Of bronze *Pelargoniums* Zulu is far the best, the zone being much darker than any other, almost black, habit dwarf and free, the very finest; the effect of this in the mass being very striking, flowers salmon. Black Douglas is the next best, the flowers light salmon. Maréchal MacMahon still unsurpassed as a bedding, broad zone and very bright, habit excellent. Dragon has a chestnut zone and light salmon flowers, habit dwarf and free. Beauty of Calderdale is still a favourite in the light bronze, and is free, even strong in growth. Of gold, Crystal Palace Gem is most in repute. *Calceolarias* are grown by the ton thousand; the best yellow is Golden Gem, best dark bronze Ion, and yellow and brown Sparkler.

*Alternantheras*, judging by the quantity grown, show no diminution of the popularity of carpet bedding. The collection of these is very rich. *A. versicolor grandis* is the strongest grower, foliage dark bronze with rich magenta red marking, very distinct and effective. *A. amœna spectabilis*, brilliant magenta, red, or scarlet, the highest in colour of all the family, and a great acquisition, freer and stronger than *amœna* in habit. The New Golden—viz., *aurea nana*, completely eclipses all others with yellow-coloured foliage. It grows so free and yet so compact as to be quite a gem, its bright golden yellow foliage rendering it most effective, distinct, a decided acquisition. These three are the best of *Alternantheras*. The others grown are *paronychoides*, thick grower, forming round clumps about 4 inches high, brown bronze, tipped red; *paronychoides major*, bronze, orange tips, good; *paronychoides major aurea*, golden yellow, which is kept throughout the season; *magnifica*, a sport from *paronychoides*, but larger and a much higher colour; *amœna*, magenta red; *amœna tricolor*, bright in colour; *amabilis*, orange and red; *amabilis latifolia*, more vigorous grower and richer in colour; *amabilis tricolor*, a vigorous grower with green margin. The three first named are, however, a long way ahead of the others. *Coleus Verschaffelti* is grown extensively for bedding purposes, the demand for which shows no abatement, but is rather an increasing one. *Ageratum Cupid*, a free bloomer, and the dwarfest of all, and *Conness of Stair*, are grown in quantity, also *Heliotropes*, and many other plants. A fine batch of *Vallota purpurea* is grown in 5-inch pots, it being much in demand for late summer decoration.

At Brampton Messrs. Wood & Ingram have nurseries to the extent of over sixty acres devoted to Roses, fruit trees, Conifers, ornamental flowering trees, and shrubs; and a seed farm of upwards of fifty acres in another district, the whole under excellent management by their respective foremen in the several departments.—G.

## WINTER GARDEN AT THE FIRS, LEE.

THE engraving, from a photograph by Messrs. Perkins & Son, Lee, represents the interior of this structure, the dimensions of which are:—Length, 70 feet; width, 30 feet; depth from centre ridge to path, 18 feet. In form it is a three-quarter span, western aspect, and was erected by Messrs. Weeks & Co. of Chelsea several years ago, for the purpose of growing late Grapes and Oranges. For many years splendid crops of Lady Downe's Grape were grown in this structure. Its use as a vinery was discontinued ten years ago, and Mr. Larking conceived the idea of turning it to its present use, the beds and banks being formed under his direction—that is, the outline of them—his present gardener, Mr. T. W. Sanders, being allowed to make improvements by adapting the beds to the requirements of the plants.

On the left-hand side of the structure is a bank 6 feet deep, divided in the centre by half a dozen stone steps, which lead down from a gravel path, 3 feet wide, that runs along the top of the bank to the path shown in the engraving. The soil forming the bank is supported in position by means of large boulders of Kentish ragstone disposed in a bold informal manner. The outline of the bank consists of this stone, which here and there projects boldly. Nooks and crannies are formed, which vary in size and treatment according to the distance from the foreground and the character of the plants used. The engraving shows about two-thirds of the interior, and in the part not shown are the seats and table, which form the coign of vantage, so to speak, from whence the arrangements of the beds, rocks, and plants are made. The right-hand side arrangement shows a couple of beds, the one in the foreground being smaller than the farther one. A gravel path runs behind these beds and joins the broad one at the far end, and a short gravel path also intersects the two beds leading to another flight of stone steps, which descend into an octagon annexe devoted to tropical plants. A narrow stage runs along the ends and right-hand side, not so much for the purpose of holding plants as to cover the treble rows of hot-water pipes, of which there are over 400 feet. The front of this stage is covered in an irregular manner with virgin cork, which projects sufficiently low to hide the first row of pipes and intercept the straight lines of the remaining ones. In order to further conceal this outline, or at any rate to break the straight lines, Mr. Sanders formed a narrow irregular border, and planted such bold-growing Ferns as *Pteris tremula* and *argyræa*, &c. These grow freely, and by a little tasteful arrangement of the fronds the desired result is obtained. These Ferns have to be supplied copiously with water every day throughout the year to keep them in a healthy condition.

The two large beds are interspersed with stones of considerable size in the upper portions, whilst all round the margins small beds occur

similarly to those on the margin of the opposite bank. The greater the distance away from the eye the larger the stones and the size of the smaller beds. In the arrangement as shown in the photo, the plants increase in size as the distance increases. Beginning with the small bed at the foot of the first mound there is a group of choice Alpine Auriculas and *Primula obconica*, carpeted with *Selaginella Kraussiana*. Growing out of the cleft of a couple of stones is a plant of *Nephrodium molle*, with *Enpatorium riparium* to the right, *Le Flambeau* Azalea nestling in between, and Azalea Fielder's White, with snowy white bloom, resting against a background of foliage of the Citron Tree, *Acacia dealbata*, *Camellia*, and a large plant of the broad-leaved Myrtle. *Cytisus racemosus*, dwarf Azaleas, *Spiraea japonica*, Roses in pots, *Amaryllis*, *Callas*, *Spiraea*, *Thunbergias*, *Deutzias*, *Boronias*, *Ericas Cavendishiana*, *ventricosa*, *perspicua nana*, and *persoluta*, interspersed with various forms of bold-growing Ferns, occupy the upper portion of this mound, whilst *Primula obconica*, Lily of the Valley, &c., fill the little beds at the base.

In the larger and farther mound groups of *P. obconica*, *Cinerarias*,

table. Behind this is a rockwork planted with Ferns, and in the right-hand angle is a plant of *Strelitzia Regina* planted out and quite at home. In the opposite corner is a healthy thriving plant of *Luculia gratissima*, only planted a year ago. This end of the house is built up with brick and not with glass, as at the other end. Large plants of *Bomarea Carderi* and *conferta*, *Habrothamnus Newelli*, *Quisqualis indica*, and *Hoya carnosus* cover this wall attractively. A splendid plant of *Maréchal Niel*, only seven years old, covers two-thirds of the roof, and yields thousands of blooms during the winter and spring. Other creepers, such as *Plumbago capensis*, *Bignonia grandiflora*, *Mandevilla suaveolens*, *Jasminum grandiflorum*, *Gloire de Dijon* Rose, *Lasiandra macrantha* are growing more or less vigorously on this side; whilst on the opposite end *Thunbergia Harrisii* covers space with its foliage in summer, and on the opposite side *Ipomoea Leari*, *Tacsonia Van Volkemi*, *Clematis indivisa lobata*, and *Tecoma jasminoides* are growing vigorously. The majority of these creepers were planted there two years ago. All the potted plants are plunged—that is, the pots are below the surface of the soil. This

Fig. 69.—MR. LARKING'S WINTER GARDEN.

Lily of the Valley, and small plants of Zonal Pelargoniums adorn the base; behind these are a few large boulders of stones, among which are large plants of *Cytisus racemosus*, various coloured Azaleas, Myrtles, *Callas*, *Verbascum*, *Agapanthus umbellatus*, *Acacias*, *Oleanders*, with a huge plant of *Rhododendron ciliatum*, *Camellias*, standard *Heliotrope*, *Rhopala*, &c., for the background, the far end of this mound being crowned with a fine plant of *Kentia Belmoreana*, which stands boldly with its foliage spreading over the group, giving a finish to the picture. The opposite bank has very large plants of *Camellias*, Japanese Medlar, Lemon and Orange trees, *Acacias*, a large standard Azalea (Fielder's White), and *Chamaerops excelsa* to form the background, the foliage of which rises to the roof, whilst dwarf Azaleas, *Deutzias*, *Spiraeas*, *Ericas*, *Cinerarias*, *Primula obconica*, Ferns and other miscellaneous plants furnish the various beds in the bank. The bank on this side of the steps contains a fine plant of *Araucaria Rulei*, large plants of *Acacia Ricciana*, *Oleander*, *Rhododendron Princess of Wales*, *Olea fragrans*, *Latania borbonica*, and large specimens of Azaleas as a background, to smaller plants of Azaleas, *Spiraeas*, *Deutzias*, *Cinerarias*, *Callas*, *Imantophyllum*, *Solanum capsicastrum*, and Roses in pots. This bank sweeps with a gentle curve, and its lower part contains ledges and beds in which choice flowers are placed.

The part not shown consists of ground space for the chairs and

practice entails trouble and responsibility in the matter of watering, unless assistants are capable and trustworthy, take an interest in their work, and exercise great care in examining the plants every day when watering. Mr. Sanders says—"I am glad to say I have trustworthy young men, and not in one instance have I lost a valuable plant through neglect since I have had charge here; but my employer tells me the death-rate was something frightful previously."

In plunging, care is taken to provide a sound base of brick or slate for the pots to rest on, and also to see that every plant has its roots sufficiently moist before doing so. To this matter Mr. Sanders gives personal attention, and he observes:—"As I rearrange the house from time to time I invite my employer, who is a skilled artist, to point out any defects or suggest any improvements, and this he feels a pleasure in doing, as I do in receiving his just criticism and advice whenever needed. I work in sympathy with his views, and he in return gives me the best encouragement by imparting to me the principles of the beautiful in gardening as admired and studied by him."

In all the arrangements in the winter garden no plants are employed which will not harmonise with each other and the building. Thus, for instance, the Aloe family, or *Dracena*, or *Primula sinensis* type, with rigid foliage, are not admitted therein, because they do not blend with the foliage of Palms and Ferns. Finally, the winter garden is not kept furnished

after May until September. A temperature of 50° is maintained by day in winter. *Isoplepis gracilis*, *Selaginella*, and *Tradescantias* cover the bare ground as much as possible; also the various plants remain in bloom much longer when plunged than when their pots are exposed to the open air.

The octagon contains large plants of *Areca sapida*, *Pritchardia macrocarpa*, *Seaforthia elegans*, *Neottopteris nidus-avis*, *Araucaria excelsa*, &c., and the following creepers planted out—*Combretum purpureum*, *Passifloras*, *Buonapartea quadrangularis*, *Descainiana*, and *Impératrice Eugénie*, *Aristolochia gigas*, *Hibbertia dentata*, and *Rhodochiton volubile*.

The fernery, parallel with and adjoining the winter garden, contains two large Tree Ferns of note, *Cyathea medullaris*, *Cibotium princeps* and *Scheidel*, *Dicksonia squarrosa*, *D. antarctica*, and *Todea arborea*. *Monstera deliciosa*, *Lasiandra macrantha*, *Stauntonia latifolia*, *Lapageria rosea* *superba* and *alba*, and many other plants, contributing to the admirable appearance of the house. It is quite as enjoyable as the winter garden, and merits a fuller description than can now be accorded. One thing is clear—both Mr. Larking and his gardener are adepts at the tasteful and picturesque arrangement of plants.

### THE CULTIVATION OF THE STRAWBERRY IN POTS.

IN continuation of the social monthly meetings of the Lee, Lewisham, and Blackheath Horticultural Society, held in the Working Man's Institute, Old Road, Lee, the following brief, practical, and instructive paper on "the Cultivation of the Strawberry in Pots" was read by Mr. Fox, gardener to Mrs. Penn, The Cedars, Lee, before the members at the last meeting on the 26th ult.

After a few preliminary remarks by Mr. Fox, in the course of which he stated that he did not propose to offer any novel ideas on the subject, but rather a few practical hints which might prove of service to those who had had less experience than himself, and which would if practised as he advised, enable them to attain success, he plunged into his subject.

"The first thing of importance," said he, "is the compost, and I know of nothing more suitable for the purpose than good loam with a liberal quantity of well-decayed cow or old hotbed manure, both loam and manure being thoroughly incorporated by frequent turnings. If the compost can be prepared some considerable time before it is required for use it will be all the better. This, however, is not absolutely necessary, indeed is frequently impossible to do, owing to pressure of work, until the moment it is required for use. Then we use 3-inch pots for layering and 6-inch pots for growing and fruiting the plants in. I have tried larger sizes for the latter purpose, but my experience will not justify me in recommending a larger size than 6-inch, which size is in my opinion sufficient for all practical purposes.

"The pots and compost being in readiness, the next task is to secure the runners, which should be done as early as possible—say the last week in June, as the first will, as a general rule, form by far the strongest plants. The following is the simplest mode of layering the runners:—Have the 3-inch pots filled with the compost and carried to the Strawberry bed, and with a pot in one hand and a trowel in the other plunge the former up to the rim by the means of the latter, afterwards placing the young plant on the surface of the soil in the centre of the pot and making it secure by means of a small stone or peg. Strict attention must be paid to keeping the soil moist in the pots during dry weather, so as to encourage the speedy formation of roots. As soon as the young plants are well rooted detach them from the parent plant and remove them to a convenient place for watering.

"The final potting should be commenced as soon as possible after the young plants are removed from the bed, and continued as fast as circumstances will permit until the whole are finished, which should, if possible, be accomplished by the first week in August. The plants will thus have a long season in which to make a good growth and ripen their 'crowns.' Without good plump and well-ripened crowns it is useless to expect to obtain a successful crop of fruit, a fact I would strongly impress upon the attention of those who have had little or no experience on the subject. As the plants are potted they should be stood on a bed of coal ashes in a good open position. Should the sun shine very powerfully on them they must be shaded for a few days until the roots have taken hold of the new soil, after which the shading must be discontinued.

"The plants should be carefully attended to as regards keeping the runners removed as fast as they appear, also weeds, and supplying them with water. The syringe must also be freely used, or that dreaded enemy the red spider will appear and will be found difficult to suppress, thus preventing the plants from making rapid and uninterrupted growth.

"There is another enemy we have been troubled with during the last two years, and which I have never before seen on the Strawberry. It is a small bluish green caterpillar (presumably *Phlanana Vanaria*, the same insect which commits such havoc conjointly with the larva of the magpie moths on the Gooseberry), and attacks the young foliage, stripping it off if not at once got rid of by hand-picking or other means. Next to hand-picking the best remedy I know of is to sprinkle the foliage with white hellebore powder, or make a solution of it and then dip the plants in. I have tried both of the latter remedies, and where, as in our own case, over a thousand plants are grown annually, and time will not permit us to adopt the hand-picking, the last-named methods are the most expeditious.

"The pots may be stood close together at first, but as the plants increase in growth and size more room will be required to enable the foliage to have the full benefit of light and air, and thus become stout and healthy instead of being drawn and sickly-looking. As the pots become full of roots the plants will be greatly benefited by being watered with diluted liquid manure or an occasional sprinkling of Clay's fertiliser. As the

season advances, with its shortening days and less sun, less water will be required.

"We now pass on to the storing of the plants during winter. Although the Strawberry is a thoroughly hardy plant some protection is needed when it is grown in pots to save the latter from being damaged by frost. Moreover, we must not forget that the roots growing round the sides of the pot would also suffer greatly were the plants not to receive some slight protection. Of course opinions differ as to the best modes of storing them for the winter, but I give preference to cold pits or frames where available. As we cannot always command these I have ours plunged in a bed of ashes at the foot of the front wall (outside) of a long range of Peach houses. Lights and wooden shutters are placed over the plants, the lower parts of which rest on empty flower pots, and thus allow a free circulation of air among the plants. There is, it is true, a slight disadvantage in this system, as during very severe weather the plants would be frozen; but even this may be overcome by putting an ample covering of mats or litter on.

"As to the question of the most suitable structures adapted for forcing the Strawberry there can be no doubt as to the superiority of a special house for that purpose, but as my experience does not extend to a special structure I shall confine myself to describing my own practice in forcing on shelves in ordinary fruit houses. I usually take my first plants in when I close the first Peach house, which is generally done in the early part of January, and there they come on gradually with the Peach trees. Fresh supplies are brought in as required, and I always endeavour to get the first supply of fruit ripe by the first week in April, and to maintain thenceforward a constant supply daily. The plants are stood in saucers on the shelves, and until fruit is set are supplied with pure water only. After the fruit has begun to swell we commence to treat the plants liberally with liquid manure or Clay's fertiliser, watering them twice a day to assist the fruit in swelling rapidly. Great care is now necessary in seeing that the plants do not suffer from want of water, otherwise the fruit will fail to attain a large size or a good flavour. As soon as the fruit has reached the ripening stage the plants are lifted out of the saucers, and no more water is given than is requisite to prevent the leaves from flagging. On hot sunny days it is sometimes necessary to give a little more water, because the fruit will become heated and lose much of its flavour if allowed to get too dry at the roots. This, however, is a question requiring the exercise of a little judgment. The flavour is a most important point, for no matter how large in size or rich in colour the forced fruits of Strawberries may be, if it lacks flavour it will not be appreciated.

"The varieties we grow are *Vicomtesse Héricart de Thury* and *British Queen*. The first named is our principal one, and a very fine variety it is."

An interesting discussion followed the reading of the paper, each speaker taking up parts of the subject which had been left unsaid by the other. One member pointed out the value of placing thin turves on the shelves on which to rest the pots as being far superior to saucers. The roots would penetrate through the bottom of the pot into the turves, and thus receive an additional support in the shape of a cool moist medium for its roots, and not only this, the turves would receive the surplus manurial elements which often passed through the soil and out of the pot without losing much of its value, and consequently was wasted.

The same speaker also advocated the employment of crushed bones instead of potsherds, except one piece over the hole for acting as drainage in the growing pots. This he had practised with great success, both plants and fruit being remarkably fine. His practice was to place about 1½ inch of the crushed bones in the 6-inch pot, and as a rule before many weeks a mass of roots had taken possession of the boxes. Reference were also made by him to the early history of Strawberry forcing, stating on the authority of Switzer and other writers that Strawberries were forced on dung beds as early as the sixteenth century. Daines Barrington, an old writer, states that King Charles II. had forced Strawberries and ice creams at a grand dinner in the month of April. The mode of preparing and forcing the plants was, however, not a very simple one judging from the following extract taken from Hill's "Eden," published in the early part of the last century.

"There is one kind that succeeds better than the others. This is the scarlet Strawberry. It will be proper to mix three or four plants of the great Chili Strawberry among them. These with good management will succeed, and their fruit, which is as big as a pullet's egg, will make a fine figure among the rest in the dessert. Let as many middle-siz'd pots be provided as will stand in a moderate hotbed, bring in some dry earth from the turf in a rich pasture, and shake in among it a little wood soot and some fat marle; or, in want of that, a little soft chalk. With this, when well mixed, cover the bottom of the pots 3 inches deep. Let a hotbed be got ready, and let care be taken that it has an equal and moderate heat. Let the gardener take the opportunity of the first mild day, when the earth is loosened from the preceding frosts. To take up the plants in this manner he must mark the strongest roots in his scarlet Strawberry beds, which he will easily distinguish at this season if they have been managed as we directed. The pots must be brought to the place, and these plants taken up by cutting in all round them. If there be any mix'd roots let them be trimm'd off, and let the plant with its ball be plac'd upright in the pot; then fill up with the compost and draw a little of it about the head of the plant." This writer after advising the pots to be plunged up to the rim in mould on the hotbed, goes on to say, "In tolerable weather let them have air, and let them be water'd often a little at a time. This will bring them forward very fast, and the heat of the bed being kept up by fresh dung at the sides the fruit will ripen in quantity and be tolerably well tasted. The Chili pots will require more water than the others, and they should be plac'd at the corners of the bed."

The foregoing is copied verbatim from the Jannary calendar in the

above-named work. A great stride has been made in forcing Strawberries since then. Mr. Pavey spoke at great length on the different methods of storing Strawberry plants during the winter. The particular methods to be adopted should, he thought, be regulated by local circumstances, and also on the sometimes practised mode of securing late Strawberries by planting the plants out in prepared beds in frames. Other members joined the discussion, corroborating for the most part the remarks which fell from Mr. Fox and succeeding speakers. The meeting closed with a hearty and unanimous vote of thanks to Mr. Fox for his able paper. It is a great pity these social meetings are not more generally adopted than they are. Such meetings are not only valuable from an instructive point of view, but are also the means of bringing men together, uniting their interests. Mr. S. Reece, a well-known local exhibitor of plants, will contribute the next paper on the Cultivation of Hardwooded Heaths.—T. W. S.

### FLOWER GARDENING.

IN recent years there has been a great decrease in the fancy for sensational flower beds, borders, and parterres; the stiff formality of the Dutch styles gave place long before I can remember to Italian and French styles, the chief recommendations of which appear to consist of intricacy in design, with beds and borders of brilliant flowers. The most that can be advanced in their favour is their brilliancy in bright weather from July to September, the display afforded for so brief a period being gratifying to townsmen. There is nothing in beds of such flowers arranged with a view to effect but what can be taken in at a glance, and yet we are constrained to admit that most garden visitors go expressly to see, not study, flowers, and unless there is something brilliant to attract, something intricate or elaborate in design to rivet attention, and something novel in arrangement to awaken interest, there is a lack of appreciation.

For public gardens, promenades, and parks there is no gainsaying the suitability of the bedding-out system, or the geometrical style of laying out with plants that afford a display at the time when the parks are most frequented—namely, the summer season, and I make no question of the bedding system holding its own against any mixed style of planting, for whatever may be advanced against the bareness of the beds in winter that is of little moment, as such places are then altogether neglected. Beds of shrubs are at best extremely tame or uninviting to the town denizen. It is different with spring-flowering plants and bulbs. The spring and early summer display is very much appreciated, and effort in this direction is to be encouraged, as beds of spring flowers through the variety of their forms, their varied hues, and the succession in which they are produced, are interesting and instructive. Beds of Snowdrops, Winter Aconites, Scillas, Hepaticas, and Crocuses all admire. The Hellebores show to great advantage in such company; Primulas, Violets, with Arabis, Doronicums, Wallflowers, Daffodils, Tulips, Pansies and Violas, Daisies, Silenes, and Forget-me-nots all assist in the display. In summer we have our conservatories outdoors and bright carpet beds rich in colour and harmony. In the sub-tropical garden we have Musas, Cannas, Eucalyptuses, with many others from all parts of the world. For public parks and gardens we want broad walks, open and breezy spaces gay with flowers, broad expanses of turf, trees that blend in the distance into woodland scenery, a lake, and ample space for recreation.

It is with regard to private gardens, however, that I wish more particularly to discuss the bedding-out system. I am old enough to remember the flower borders of over forty years ago, which are now referred to as the old-fashioned style of gardening. At the garden where I commenced my career there was a large mansion with north and south frontages—the south, the carriage or drive front, on which there were expanses of sloping lawn, a view over meadows, and a tidal river to the richly wooded country beyond. The lawn was flanked with noble trees, which acted as shelter from the west winds that came sweeping over a stretch of flat somewhat treeless land following the course of the river, whilst on the lawn itself were specimens of noble Cedars, Magnolias, and groups of shrubs both evergreen and deciduous. The centre was of course an open space, and immediately under the windows were the exotics, which gave a pleasing aspect from the windows. There were no formal shapes, and there were no flowers except those in semi-wildness among the shrubs or beneath the trees, as Primroses, Winter Aconites, Snowdrops, and Daffodils, with Periwinkles, &c. The north front was simply a broad expanse of lawn of ten acres, bounded on the west by plantations and shrubberies that with walks offered access, and at the same time shut off the usual adjuncts of mansions, as stables, &c., and on the confines of which were situated the dairy. Not a tree stood on this expanse of turf, a broad walk ran parallel with the mansion across it with a similar one from it to the entrance of the mansion on that side. It was in fact the foreground to the park scenery beyond with its deer and trees of Oak in noble proportions. The ground adjoining the west of the mansion was occupied by a belt of trees that concealed the offices of the mansion, and on the side were the kitchen gardens and orchard, nearly half a mile distant, there were the then customary Pine stoves, vineries, Peach houses, Cucumber and Melon pits and frames, tan and stable dung being used for bottom heat, with hot air in flues for the top heat, there being two furnaces to each Pine stove, and when fully at work there were twenty-six fires to attend to of an evening, which gave me a perfect recollection of the good old times, as we now have more work done by one boiler than was then done by the twenty-six furnaces, and with greater certainty of result, as the flues were very liable to be overheated and emit sulphury vapour.

Adjoining the drawing room to the east of the mansion was the con-

servatory some 90 feet long and about 24 feet wide, with a curvilinear roof, the height being corresponding to the width. It was not all wood in mullions, and opaque from massive meaningless cornices, but it was light, the roof being of copper sashbar, and the astragals were light in proportion; and it were heated with hot-water pipes, having taken place of a building not very different from the mansion in respect of architecture and means of admitting light. I need not tell what this was like, as there are only too many such conservatories now existing. Beyond this eastward went a wood, through which the drive passed, and in the wood were walks, here and there stretches of turf or open spaces where bracken, wild Roses, with wild flowers, grew in profusion. In front of this wood to the south were the flower garden, and as the wood curved inwards, or to the south, it was sheltered from northern and eastern winds, whilst west winds were checked by the trees on the south front before alluded to. This enclosure was some thirteen acres in extent, although it seemed very much less, as it was profusely decorated with flowering trees, shrubs, and plants that caught the eye in every direction, being a rich mass of floral beauty in the foreground, heightening in interest and beauty as we examined it; now a mass of China Roses with climbing varieties on arches, blended with Honeysuckle, the next being the brilliant scarlet Tom Thumb Pelargoniums with yellow Calceolarias. There were beds of Cape Pelargoniums and Fuchsias, of tall Lobelias, Verbenas, Heliotropes, and Petunias, masses of Musk, and Night-scented Stocks, there being few variegated Pelargoniums, the best yellow being Golden Chain. There was a rosery in the flower garden almost exclusively formed of summer Roses, with pillars and arches loaded in their season with clusters of fragrant flowers. A wide border, a mixed mass of plants—Hollyhocks at the back, its Dahlias, Larkspurs, in declining height to the front with its Pinks and Carnations, Ten-week Stocks, and Asters, with other annuals both half and full hardy, Sweet and Everlasting Peas, something of almost everything that made a show and was useful for filling the flower basket, grand masses of Anemones for early summer and Gladioli for summer and autumn. There were water plants, a lake-like stream running through the ground, having its Weeping Willows and Birch on the margin; rock garden, so far as meagreness of rock could make it, with its rookery made to serve in grotto-like form for Ferns, bowers enshrouded in Clematis, and other winding climbers, and in a secluded spot were cherished varieties from Dean Herbert's garden at Spofforth, and which were mostly bulbs from the Cape of Good Hope or hybrids.

There were always flowers to be had for at least nine months in the year, but I must briefly sketch something else, and which unfortunately we do not now find in one garden often. It was a piece of ground shut off by low-growing shrubs, which whilst sheltering from winds were open, sunny, and this was devoted to florist's flowers—Roses, Pinks, Carnations, Picotees, Hollyhocks, Dahlias, Pansies, Polyanthuses, Auriculas, Anemones, Ranunculuses, and Tulips. Anyway, there were besides beds of these a house for Auriculas, pits, frames, and handlights for propagation, with cool quarters for such as needed it. Here everything had name, and by such seedlings were judged, and it was astonishing how few could hold up their heads with the named varieties, the quantity of seedlings not exactly up to the mark coming in admirably in the mixed border, where they made a display that everybody admired.

Whilst I was there we got into the custom of wintering Pelargoniums in vineries, making the old gardener use sundry expletives, yet the system grew, and he died before he had seen the waning of the mixed system. The massing system has been attributed to several, but there is not the least doubt that it originated with Loudon, as we find it much advocated in both arboricultural and floricultural articles by him in the "Gardener's Magazine," and John Caie certainly put the system in practice so far back as 1835. Of all its advocates none brought it so much into prominence as Donald Beaton in the pages of the *Cottage Gardener*, it not being until 1850 that the system had obtained a hold of the gardening mind demanding particular note. It was not enough to relegate perennials to mixed borders, but these last must be cleared to make way for new fashions; ribbons of flowers or foliage as varied in hues as those of the rainbow, even beds of choice plants must be relegated to the kitchen garden, and these were ousted by the tawdry Pelargoniums and gawky Calceolarias; even Vine borders must be made contributory to the colour hunger. This was not enough, fresh beds must be cut on every available piece of lawn within view of the principal windows, until there were almost as much bed or border as lawn. It was a conglomeration of flowers of the brightest and most transitory character, as a spell of wet weather rendered the Pelargoniums petalless, and Calceolarias dropped their flowers, everything being forlorn except foliage plants that seemed to heighten in effect in murky weather. This, with the change of glare and neglect of tone, gave rise to the carpet bedding system, which speedily became popular.

That the bedding system did not entirely obliterate every sentiment of the old-fashioned style of gardening, ample evidence was given in the remarks made from time to time by those attached thereto. Beds have now taken their proper place in gardens by being brought together into some position where they form an harmonious whole in distinct feature, which everyone must admit is a great gain on the disconnected and isolated bed placing on lawns without any regard to the production of a whole, the removal of any one of its parts would disarrange the whole. This the bedding system has done for us in a manner highly creditable to landscape art. It is vain to talk of the bedding system being exploded, it only seems to be finding its proper level and fit place in gardens, which is in the geometrical and symmetrical arrangements of beds with a view to effect at stated seasons, and for which materials are forthcoming

in number and variety equal to the emergency, and that without exerting any great strain upon the resources of the establishments.

There has been, of course, a considerable relapse in the bedding-out system of late years, and a return made to the better, because more useful, method of filling borders with herbaceous plants and shrubs, that, from the variety of plants, available flowers in every month of the twelve can be had when the weather is mild. It is useless to attribute this waning of the bedding system to a change of taste, for the taste for show is just as strong as ever, with those that are not liable to be taxed with its cost. What we want, and are coming to, is a less number of beds better filled. It is the taste for the beautiful and sweet that has been given by the unobtrusive workers of floricultural art, to whom the change is due. Roses, Carnations, Pyrethrums, and plants of that kind are taking their proper place in gardens, and in the appreciation given them by cultured minds in homes of taste, not the least of the causes telling on the bedding system being the curtailment of establishments through reduced means of maintenance.—G. ABBEY.

## COLONIAL AND INDIAN EXHIBITION.

### THE VEGETABLE PRODUCTS OF INDIA.

THE general extent and interest of the Exhibition at South Kensington were referred to last week, but as the vegetable products of the Colonies form such an important part of the contributions they merit a more detailed description, which it is our intention to accord them in the following notes.

First in importance, and the first also that a visitor sees when entering the Exhibition by either of the gates nearest to the South Kensington station, are the Indian courts and galleries. In these are displayed an exceedingly choice collection of works of art, and with them are associated samples of the chief vegetable products, dried or otherwise preserved, represented by models as in the case of some of the fruits and vegetables, or by coloured illustrations as with some of the rare or most remarkable plants. It is unfortunate, however, that there are no living representations of the rich tropical Indian flora beyond what are afforded by the Orchids in the St. Alban's House. These, it is true, are numerous and beautiful, but our stoves and other houses are embellished by so many handsome plants from the East Indies, that a house devoted to them would have constituted a valuable addition to the horticultural attractions. The Himalayan Rhododendrons alone would have furnished a house admirably, but probably some descendants of at least one Indian Rhododendron, *R. arboreum*, will be found amongst those out of doors that will shortly be flowering in the beds facing the fountains. Numerous and varied as are the ornamental plants from India, those distinguished for their uses are also abundant, and some of these are of much importance to us, and are in various forms imported to the country in large quantities. It is strange, however, that many of the plants cultivated extensively for exportation are not natives of the country, though there are plenty of plants of economic value indigenous to India, but the majority of these are used by the natives for various medicinal purposes. A glance at one of the Indian "shops" in the Exhibition will illustrate this—namely, the druggist's or herbalist's, in which great numbers of dried herbs are shown, each supposed to possess some marvellous properties, and some undoubtedly are useful in disorders peculiar to the country. The other "shops" are also interesting, especially the fruiterer's with the innumerable tropical fruits, amongst which the Bananas and members of the *Gonrd* family predominate, and the grain-sellers' with a variety of millets and lentils so largely employed there as food. The models of fruit and vegetables from the Botanic Garden, Saharanpore, are also worthy of attention, several being shown with which we are familiar in the London markets, such as the Litchi; those seldom used here, but in much esteem where they are produced, being the Mango and Guava, while the Pine Apple and Banana, which we obtain from several other sources, are included amongst these models.

The Forest trophy, representing 3000 specimens of useful timbers, and the Bamboo trophy are interesting features in these courts. The latter is constructed in the artistic manner that characterises so much of the native work, two staircases having been formed with a platform at the top, the steps formed of strips of Bamboo arranged in a great number of geometrical designs, like the inlaid work of cabinet makers. It is said that no less than thirty species of Bamhusa have been utilised in the construction of this trophy, and the stems employed vary in size, from the size of straws to giants nearly a foot in diameter. The uses of the Bamboo are very numerous, especially in the construction of the light airy dwellings and furniture of tropical India; but there is another plant which is also remarkable for the multiplicity of its uses, the Cocoa-nut Palm, *Cocos nucifera*, of which a series of objects is shown near the Bamboos. About eighty specimens are exhibited, but these might be greatly multiplied, for the bare enumeration of the uses to which the different portions of the plant are applied would fill a small volume. Like the Bamboo the stems are employed for dwellings and furniture of many kinds, but in this case we have a nutritious fruit that is also borne in considerable quantities, the covering of which yields an important fibre, the leaves are used for articles of dress, and in a young state for food. It has been truly remarked that it is "one of the richest of Nature's gifts to man, for there is no part of the plant that is not adapted to human necessities," and to the inhabitants of many tropical countries besides India the Cocoa-nut Palm is indispensable.

Of the plants the products of which are mainly sent to Great Britain the Cinchona merits a special note, as the culture has increased considerably in recent years, owing largely to the efforts of the home authorities, amongst whom must be mentioned those at the Royal Gardens, Kew,

As soon as it was found that the South American Bark-yielding trees would succeed in the elevated districts of India, especially in the Himalayan region, large plantations were formed by the Government at Darjeeling and elsewhere with very encouraging results, and the supply of Bark from India has been increasing for some time, exclusive of that consumed in the country where its febrifugal properties can be so fully appreciated. There are numerous kinds of Bark, but they are grouped as follows in the Kew collection:—Pale Cinchona or Crown Bark, *Cinchona officinalis*, Yellow Cinchona or Calisaya Bark, *Cinchona Calisaya* (fig. 70), and Red Cinchona Bark, *Cinchona succirubra*. Our non-botanical readers may not be aware that the family to which the Cinchona belongs also includes the Coffee, Ipecacuanha, and Madder plants, as well as some

Fig. 70.—*Cinchona Calisaya*.

of the most ornamental plants cultivated in our houses, such as the Gardenia, the Rondeletia, and others. The properties of the Cinchona depend chiefly upon the alkaloid quinine, which is present in the bark, and found to be a valuable tonic.

(To be continued.)

## ROYAL HORTICULTURAL SOCIETY.—MAY 11TH.

A VARIED and handsome display was provided in the conservatory at South Kensington on Tuesday, the stages on each side of the building being filled with Roses, hardy flowers, Orchids, Rhododendrons, and other exhibits. The specialties of the occasion were, however, Messrs. W. Paul & Son's superb Roses, Mr. T. S. Ware's interesting hardy flowers and Tree Pæonies, Messrs. Lane & Sons' Rhododendrons, and the Colonial exhibits of Apples and other fruits.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq., in the chair, and Messrs. John E. Lane, Wm. Denning, J. Ellam, W. Warren, G. T. Miles, G. Norman, Arthur W. Sutton, John Burnett, F. Mason, F. J. Saltmarsh, Philip Crowley, R. D. Blackmore, T. B. Haywood, Harrison Weir, George Bunyard, and Chas. Silverlock. The collections of Apples from Australia were the principal exhibits before this Committee. A collection of Apples was shown by Mr. James Lang, Harcourt, near Castlemaine, Victoria, Australia, sent by request of Mr. John Carson, Melbourne, to the care of G. F. Wilson, Esq. They had been grown in a soil of decomposed granite, and had been packed in soft paper and cotton wool. The fruits were large, fresh, solid, and mostly of fine flavour. Northern Spy was highly commended. Reinette du Canada, very large, was commended, as also was Perfection, a bright red Apple of medium size, very firm, and good flavour. Other notable varieties were Scarlet Nonpareil, Worcester Pearmain, Dumelow's Seedling, Merritt's Pearmain, London Pippin, and Cleopatra. J. T. Pascoe, Esq., sent two dishes of South Australian Apples, Strawberry Pippins, and Cleopatra, the latter being commended. The Hon. R. D. Ross, Higher Combe, South Australia, and R. Devonport, Esq., also sent dishes of Apples, one variety named Mobbs' Royal, a large green Apple, being commended. G. Quick, Esq., had some fine Quinces, Mrs. Holbrook fine fruits of Napoleon Pears, which were commended, and T. Hardy, Esq., Adelaide, had samples of Brande's Almonds. A collection of dried fruits was shown by Lady Davenport, Beaumont, Adelaide, Australia, comprising Currants, Moor Park Apricots, Raisins, Prunes, Sultanias, Napoleon Pears, Gravenstein Apples, and Reine Claude Plums. They were all very clean excellent samples, highly commended for their excellent quality. The Committee requested that the dried Apples and Pears should be stewed and exhibited at the next meeting. A collection of Apples from Canada was also shown by the Canadian Commissioner, representing some highly coloured varieties, Ben Davis, Northern Spy, Phoenix, Seek no Further, King of Tomkin's County, Canada Red being some of the best. It was proposed that Knightian medals be placed at the disposal of the Commissioners for Australia and Canada and Mr. Lang of Victoria.

Mr. W. Divers, Wierton Place, near Maidstone, sent thirteen dishes of Apples and Pears which had been "kept since gathered in a cold dark room where the temperature often fell considerably below freezing point in the winter," but the samples of King of the Pippins, Hanwell Souring, Graham's Russet, and Loddington Apples were fresh and good, the Pears Catillac and Chaumontel being moderately good. The Veitch Memorial prize, for a collection of forced salad plants not less than ten distinct kinds, was won by Mr. G. Bolas, gardener to H. Chandos Pole Gell, Esq.

Hopton Hall, Wirksworth, Derby, who had examples of Chicory, Whitloof, Chervil, Tarragon, Dandelion, Celery, Beet, Chives, Onions, Cucumbers, Radishes, Rampion, Mustard, Cress, and Sorrel.

**FLORAL COMMITTEE.**—Present: G. F. Wilson, Esq., in the chair, and Messrs. J. Douglas, H. Bennett, W. Bealby, Amos Perry, H. Herbst, W. Wilks, J. Walker, Shirley Hibberd, James Hodson, G. Duffield, G. Paul, R. Dean, William Holmes, H. Ballantine, John Dominy, H. M. Pollett, James O'Brien, Harry Turner, Thos. Baines, H. Cannell, A. F. Lendy, W. B. Kellock, and E. Hill.

Messrs. J. Veitch & Sons, Chelsea, contributed several plants, a basket of the dwarf *Rubus arcticus*, with bright rose-tinted flowers being very pleasing. (Vote of thanks.) *Philadelphus microphyllus*, with small leaves and abundant small white flowers, was well shown. (Vote of thanks.) Also the pale yellow *Sparganium præcox*; the Bird Cherry, *Cerasus Padus*; two pretty *Gloxinias*, named respectively *Diana* (purple edged white) and *Rosine* (scarlet edged white), and an elegant Fern, *Pteris Bausei*. Messrs. Barr & Son, King Street, Covent Garden, had an attractive group of hardy flowers, Daffodils, Irises, Tulips, Trilliums, and *Ixias* constituting the chief features of the collection. Messrs. Paul & Son, Cheshunt, had two fine plants of *Rhododendrons*, Lady Alice Fitzwilliam bearing some dozens of its fine white fragrant flowers, R. Edgworthi, and a slightly rose-tinted variety of R. Fortunei named Mrs. Charles Butler, were similarly well shown. A plant of the striped H.P. Rose Pride of Reigate had two good blooms, bright in colour, well marked, and substantial. Half a dozen plants of the new Tea Rose Sunset, which we have previously noted, were flowering freely, and a basket of hardy plants, including *Primulas*, *Trilliums*, and *Calthas*, was also interesting. (Bronze Banksian medal.)

G. F. Wilson, Esq., Weybridge, exhibited a plant of *Potentilla argrophylla*, with silvery leaves and large bright yellow flowers. (Vote of thanks.) Mr. F. Bridger, Penshurst Place, Penshurst, showed a plant of *Zygopetalum Gautieri* with five spikes of flowers, the lip deeply tinged with purple. The plant was very strong and growing upon a stem of a Tree Fern. He also had a plant of *Dendrobium thyrsiflorum* like the variety *Walkerianum*, bearing a very long raceme of white and gold flowers. H. Voss, Esq., De Montfort House, Streatham, had a plant of *Odontoglossum Pescatorei*, a charming variety with the lip beautifully spotted with purple. (Vote of thanks.) G. Charlesworth, Esq., Heaton, near Bradford (gardener, Mr. R. Eichel), showed *Cattleya Gaskelliana alba*, bearing one flower, white with a tinge of yellow in the lip. (Vote of thanks.) Mr. Kimpton, Smeeth Paddock, Ashford, sent several *Pelargonium* sports with strangely tinted leaves. Messrs. J. R. Pearson & Son, Chilwell Nurseries, exhibited several good scarlet *Zonal Pelargoniums*, Mrs. David Saunders and W. Bealby being very handsome. Mr. C. Orchard, Combe Warren, Kingston-on-Thames, had a plant of double *Cineraria* named Mrs. John Galsworthy, white edged with pale crimson, very curious and distinct.

Baron F. de Rothschild, Waddesdon, Aylesbury (gardener, Mr. A. Bradshaw), exhibited a specimen of *Lælia purpurata* with eight spikes and twenty-four fine flowers. The plant was in excellent condition, healthy, and robust. (Vote of thanks.) Mr. G. Geggie, Bury, sent several pretty varieties of *Primula Sieboldi*, rose and crimson coloured. H. M. Pollett, Esq., Farnside, Bickley, Kent, contributed a small group of *Odontoglossums*, choice varieties of *Andersonianum*, *Wilkeanum*, *guttatum*, *prænitens*, *scepterum*, and *citrosmum*. (Bronze Banksian medal.) The New Plant and Bulb Company, Colchester, sent several Tulips, Griegi being the most notable for the bright scarlet colour with black spots at the centre. (Vote of thanks.) Mr. J. E. Bonny, 88, Downs Park Road, Hackney Downs, showed four plants of the diminutive *Phalenopsis Parishii* with small spikes of white and purple flowers. Mrs. F. Bennett, Tulse Hill House, Upper Tulse Hill (gardener, Mr. Howes), was awarded a cultural commendation for a specimen of *Dendrobium speciosum* with a dozen long spikes of bright yellow flowers.

Messrs. William Paul & Son, Waltham Cross, were awarded a silver-gilt Banksian medal for a grand collection of Roses, about fifty specimens being shown, all healthy, freely flowered plants. Some of the most notable were Madame Montet, bright pink; Glory of Cheshunt, very dark crimson; Crown Prince, still deeper; Etoile de Lyon (Tea) bright yellow; Duke of Wellington, brilliant crimson; Queen of Queens, Violette Bouyer, and Little Gem, a pretty Moss Rose of bright pink colour; sprays of the White Banksian Rose, loaded with small white flowers. A dozen boxes of cut flowers was also shown, comprising a great number of handsome blooms, Maréchal Niel being exceedingly fine. Messrs. T. S. Ware, Tottenham, contributed a superb group of hardy flowers, *Primulas* of the Sieboldi group, Daffodils, Trilliums, Irises, and *Pæonies* being especially abundant. The *Pæonies* were very much admired, the varieties being rose, crimson, and of paler tints (silver-gilt Banksian medal). Messrs. H. Cannell & Sons, Swanley, Kent, showed some handsome blooms of the yellow Carnation Pride of Penshurst. Messrs. Wills & Sagar, Onslow Crescent, were awarded a cultural commendation for two magnificent plants of *Erica Cavendishiana* over 2 feet in diameter, and loaded with flowers. Mr. J. Walker, Thame, Oxon, had a basket of *Gentiana acaulis*, brilliant blue. Mr. W. Rumsey, Waltham Cross, contributed a large group of dwarf and standard Roses, profusely flowered, and a number of boxes of cut flowers were also shown (bronze Banksian medal). Messrs. H. Lane & Son, Berkhamstead, exhibited an extensive collection of *Rhododendrons* and *Azaleas* of numerous varieties (silver-gilt Banksian medal).

#### CERTIFICATED PLANTS.

First-class certificates were awarded for the following plants:—

*Phoenix hybrida* (J. Veitch & Sons).—A pinnate-leaved Palm, of graceful habit, the pinnae one-quarter to half an inch broad, 8 to 10 inches long. The leaves on the plant shown were about a foot long, but they will no doubt come larger.

*Pæony Moulan Reine Elizabeth* (T. S. Ware).—A large full-flowered variety of a bright reddish rose tint, distinct and showy.

*Adonis pyrenaica* (T. S. Ware).—A variety of similar habit to *A. vernalis*, but with much larger brighter yellow flowers, the petals much broader.

#### SCIENTIFIC COMMITTEE.

Sir J. D. Hooker in the chair.

*Gladiolus tristis*.—Mr. Ridley ascertained this to be the species of *Gladiolus* brought to the last meeting.

*Beetroot*.—Mr. Ridley examined the specimen brought to the last meeting, and believed that a seed had originally fallen into a hole in the stone; it had then grown through it; but that a stone had subsequently been pressed into it from above and so cut off the leaves.

*Passiflora diseased*.—Mr. Michael gave the following report upon the specimen sent to the last meeting:—

"I have to report that I have examined the large outgrowth from the stem of *Passiflora edulis lancifolia*, forwarded by Mr. W. Speed of Penrhyn Castle, with a view to ascertain whether it was caused by the attacks of Phytiopti. It was in a very unfavourable state for such examination, as to make that reliable the object should be forwarded when the mischief is commencing, not when it is complete, and the conditions of the whole thing so greatly changed. The object should be taken in the earliest stage, cut with a portion of the healthy stalk, and immediately it is cut put in a sponge bag, or in gutta-percha tissue or oil-silk, and tied up so tightly that neither Acari nor moisture can escape; or a tin box will do equally well if closely fastened up, and it should be forwarded at once.

"I examined the outgrowth and other parts of the plant as well as the conditions permitted, and failed to find any trace whatever of Phytiopti; neither living specimens, nor any cast skins nor remains were to be found, even under a tolerably high power of the microscope. The outgrowth was near to a leaf bud, which, so far, would somewhat favour the idea of Phytioptus action, but there was not any indication that it arose from the bud itself, or from leaves in any stage which would be expected to be probably present if the view were correct.

"On the other hand, the whole outgrowth, both internally and externally, was absolutely swarming with myriads of Acari of the genus *Glyciphagus*, which occupied every part of it, and were in all stages, and had penetrated from the outgrowth into the portion of the stem itself, lying immediately below it, where sections of the wood revealed them in considerable numbers. There was not any sign of living creatures of any kind except the *Glyciphagi* and a few *Gamasids* which were preying upon them.

"The *Glyciphagi* would not be likely to be the first cause of mischief, but they might possibly, and even very probably, be instrumental in turning a slight and unimportant injury into a serious one. They are creatures found principally on dried fruits, seeds, flowers, and some dried animal products, as cantharides, &c., and are universally distributed and extremely abundant, doing great damage to such products as those above-named, but they do not habitually attack uninjured living plants. At the point where the outgrowth arose from the stem there was decided evidence of some injury having been sustained, although not an important one, and I could not in the present condition of the specimen say from what cause.

"The conclusion I am inclined to draw is that probably the bark received some slight injury, possibly from insects or acari, but more probably from other causes; that an exudation of sap and matter containing more or less sugar or gum occurred and happened to attract the *Glyciphagi*, who would feed eagerly upon it and breed with immense rapidity, and pursuing their search for it into the wood itself, would give rise to an irritated condition which might well cause an abnormal flow of sap and such outgrowths as the present. It is, however, quite possible that the outgrowth may have arisen from some other cause, and that the *Glyciphagi* had only come when it was dried up. It would require to have the outgrowth in an earlier stage to be certain about this. There were not any *Glyciphagi* on the other portions of the stem where the bark was uninjured.

"Finally, I would suggest that an application of carbolic acid, sulphur, or better still, tar, in an early stage of the mischief, might probably stop it, if, as I surmise, it be aggravated by the *Glyciphagi*."

*Pansy Dimorphic*.—Dr. Masters showed two blossoms, one of a dark purple, the other smaller and white, with a central purple spot, both being from the same plants. The latter appeared to be a reversion to some earlier form of *Heartease*.

*Laburnum hypertrophied*.—Mr. W. G. Smith remarked upon a specimen in which a terminal shoot had been injured by frost, in consequence of which a lateral branch had become hypertrophied. A large number of trees were similarly affected.

*Coin with Rhizomorpha*.—Mr. Smith exhibited a specimen of Cocoa-nut fibre matted together by a remarkable form of fungus. The *Rhizomorpha* consisted of silk-like threads of a dark brown colour and of an almost metallic lustre. Mr. Murray suggested that it was probably some species of *Agaricus*. It was found to damage the commodity very materially.

*Ivies Injured and Uninjured by Frost*.—Professor Church remarked that of six varieties of Ivy growing on a north wall only one (*Azorica*) was at all injured during the late severe weather.

*Deutzia gracilis*.—Dr. Lowe exhibited two specimens from the same plant, one with ordinary flowers, the other with small greenish—or so-called "blind" flowers. They were referred to Dr. Masters and Rev. G. Henslow for examination and report.

*Ergot of Wheat*.—Mr. Plowright sent specimens for exhibition. They were given to Mr. Murray for cultivation. They are mostly shorter and thicker than the common form from Rye, and are therefore suggestive of a different variety or species of *cordyceps*.

*Podisoma Juniperi*, cultivation of, on the Juniper.—The following communication was received from Mr. Plowright:—"I am sure this is the first time this has been done in England, and it has seldom, if ever, been done abroad. It is a much more tedious process than the converse culture of the *Ræstelia* from the *Podisoma*, which is done in a week or two, for this has taken two years. The germ tubes of the *Ræstelia* can enter through the stomata of the leaves, and the mycelium passes down the leaf and enters the green stem. Then it hibernates. The leaf by which it entered falls off, and two years afterwards (not the next year) the mycelium in the stems (which has shown its presence by causing a slight enlargement visible at the end of the second year) in the spring following produces the teleutospores.

"*Podisoma Juniperi*.—Although many cultures have been made by placing the mycelial spores of this fungus upon Hawthorn leaves, &c., and thereby producing the *Ræstelia lacerata* (its oecidiospore), very few have been made in the opposite direction, by placing the *Ræstelia* spores on Juniper. In the course of my experimental culture with the hetero-nemia uredines I resolved to try this experiment. For this purpose in the

year 1883 I obtained some ripe Juniper berries from my friend the Rev Dr. Keith of Forbes. In 1884, out of a great number of berries, I obtained some half-dozen seedlings. I also provided myself with two young Junipers, about 12 inches high, from Mr. Bird's nursery at Downham in 1883.

"Exp. 420.—On the 24th June, 1884, one seedling Juniper in a flower that was infected with *Ræstelia lacerata*. On 1st July it was noted that some of the leaves of the Juniper were paler in colour than the rest. On 11th August this was still more marked. 17th May, 1885, the base of the stem of the seedling was slightly enlarged, but there was no appearance of teliospores. During the summer of 1885 the plant died. It appeared as if the swelling at the base of the stem had strangled the plant.

"Exp. 421.—The two Junipers obtained from Mr. Bird were planted side by side in 1883. One of them was infected with the *Ræstelia* spores, but without result. The reason for that was that the plant had not got over the shock of its removal, and had not, at the time the infection was made thrown out any young leaves, so that the spores fell only upon old leaves. On June 25th, 1884, when it had thrown out new leaves, it was again infected. The other Juniper was covered with a bellglass in order that it might not become accidentally infected.

"July 8th.—Many of the new leaves have a paler hue. This paling of leaves is the rule when the germ tube of a *Uredium* has succeeded in entering a host plant. The first change noticeable is a sickly or paler spot, but subsequently changes colour according to circumstances.

"Aug. 11th.—The infected Juniper contrasts in appearance very strongly in foliage with the healthy one.

"Nov. 11th.—Many of the leaves which turned paler have now fallen off from the infected plant, so that it has an unhealthy appearance, a lanky habit of growth.

"May 17th, 1885.—The infected plant is deficient in last year's leaves in many places, but has thrown out new shoots and foliage. I can see no enlargements on the stems, but the appearance of the bush contrasts very strongly with that of the uninfected one growing beside it. There are no teliospores.

"Oct. 28th, 1885.—No teliospores have been produced this year, but I feel sure the infection has been successful, and that no mycelium of the *Podisoma* is present in those parts of the stems which are leafless, because they are slightly swollen.

"Dec. 3rd, 1885.—Swellings more marked.

"Ap. 1st, 1886.—The *Podisoma* has at length appeared upon the swollen parts of the leafless stems.

"Ap. 11th, 1886.—A specimen gathered and sent to the Scientific Committee, showing the mature teliospores.

"The other Juniper is perfectly free from *Podisoma*, and healthy in every respect.—WALTER B. FLOWRIGHT."

*Polyanthus*, var.—Mr. Henslow exhibited a pale-flowered variety, and a truss from a similar plant what had been treated with lime, the effect being to convert it to a crimson.

*Plants Exhibited*.—Mr. J. T. Lynch exhibited the following plants from the Botanic Gardens, Cambridge—*Crybe rosea*, *Iris Eulefeldi*, from Turkestan; *I. Turtulle*, *Heterotropa asaroides*, with a remarkable Box-like flower and Cyclamen-like leaves from Japan; *Mackaya bella*, *Kämpferia ovalifolia*, *Tulbachia Lüdwigiana*, named after Lüdwig, a snuff merchant of the Cape, who originated the Botanic Garden there, and was the first botanist to import large Cycads to England. Mr. Lynch also brought several varieties of Tulips.

## ORCHID SHOW AT BIRMINGHAM.

MAY 12TH AND 13TH.

THE Birmingham Botanical and Horticultural Society determined some time ago to hold a representative exhibition of Orchids in their gardens at Edgbaston this year, and to induce professional and amateur growers to bring their treasures together in friendly competition they provided a liberal schedule of prizes. A most favourable time was also selected for the Show—namely, the 12th and 13th of May, a period when Orchid flowers are abundant in collections, and when also the plants can be conveyed to and from exhibitions with the least risk of injury. The neighbourhood of Birmingham has become celebrated for its collections of Orchids, and the projectors of the Show were justified in their expectation that there were, few districts more likely to produce a satisfactory display of these popular plants.

Eleven classes were provided as follows:—1, Group of twenty Orchids distinct (open); prizes £15, £10, and £6. 2 and 3, Groups of ten, from amateurs and nurserymen; prizes £8, £6, and £4 in each. 4 and 5, Groups of six, also from amateurs and nurserymen respectively; prizes £5, £3, and £2. 6 and 7, Groups of ten distinct *Odontoglossums*, like the preceding for the two sections of exhibitors; prizes, £6, £4, and £2. 8 and 9, for six *Cattleyas* or *Lælias*; prizes £4, £3, and £2. 10, for twelve distinct species of *Masdevallias* (open) £3, £2, and £1. And 11, for twelve distinct cut spikes or bunches of Orchid flowers in glasses; prizes £3, £2, and £1. The total in all the classes was thus £141, the largest amount yet offered for Orchids alone at one exhibition.

The arrangement of the exhibits was under the superintendence of the Curator of the Botanic Gardens, Mr. W. B. Latham, and it is almost needless to say that he made the most of the material at his command. An exceedingly beautiful effect was produced, for Orchids lend themselves readily to artistic arrangement, being free from the formality that characterises so many exhibition plants, and are remarkably varied both in forms and colours.

The large glass exhibition house was devoted to the plants, which were admirably arranged on the side stages, with a due proportion of healthy Palms and Ferns to impart a more pleasing effect. The Orchids were not represented by the large specimens sometimes seen at other shows, but they were in nearly every case genuine specimens, and therefore better indications of the cultivator's skill. Some extremely handsome varieties were included in several of the collections, and a large number of distinct species was shown. The display was the more remarkable that with the exception of the Cheltenham plants they were all from growers in the district, and in all respects they were most creditable to the exhibitors, and

never has a more beautiful exhibition of Orchids been provided, for though the Kensington Conference last year brought a larger number of plants they were not so effectively displayed.

We can only briefly note the winners of the prizes in each class, reserving fuller note for another occasion. Class 1.—First, Mr. James Cypher, with handsome plants of *Cattleya Skinneri* oculata, *Dendrobium thyrsiflorum*, and *Cypripedium Lawrencianum*, being the finest amongst many that were good; second, A. A. Wills, Esq., with smaller plants, but freely flowered. Class 2.—First, C. Winn, Esq., with fresh and beautiful plants of *Odontoglossum vexillarium*, and *Cypripedium Lawreucianum* forming the leading attractions. The Right Hon. Joseph Chamberlain was second, and Joshua Fellowes, Esq., third, an extra prize being awarded to Edwin Wright, Esq. Class 3.—First, Mr. James Cypher, who was also first in classes five, seven, and nine, in each case showing plants of the usual high quality. Class 4.—First, Mr. Chamberlain, with six very handsome plants superbly flowered; second, Mr. C. Winn, and third, Mr. E. Wright. The *Odontoglossums* in classes six and seven were of excellent quality, Messrs. C. Winn, J. Fellowes, and Cypher taking the honours. Class 8.—First, Mr. Winn, with small but healthy plants, very distinct. Second, Mr. Chamberlain. The *Masdevallias* from Messrs. Winn and Fellowes were exceedingly bright, and the cut blooms from Messrs. Cypher, Winn, and Chamberlain very beautiful. Several groups of Orchids not in competition were awarded extra prizes. The Exhibition was a decided success, but the weather on the opening day was most unfavourable, continuous rain deterring many visitors from attending the Show.

## ROSE SHOW FIXTURES, 1886.

FOR the guidance of those Societies which have not as yet fixed the dates of their exhibitions I append the following list of Rose Shows arranged to be held during the coming season by the National Rose Society and Societies affiliated with it.

Bagshot and Windlesham Rose Society, at Bagshot, Tuesday, June 29th.

Diss Horticultural Society, at Diss, and the Canterbury and Kent Rose Society, at Canterbury, Tuesday, June 29th.

Croydon Horticultural Society, at Croydon, Wednesday, June 30th.

Farningham Rose and Horticultural Society, at Farningham, Wednesday, June 30th.

Reigate Rose Association, at Reigate, Thursday, July 1st.

Tunbridge Wells Horticultural Society, at Tunbridge Wells, Friday, July 2nd.

Brockham Rose Association, at Dorking, Saturday, July 3rd.

Eltham Rose and Horticultural Society, at Eltham, Saturday, July 3rd.

National Rose Society, at South Kensington, Tuesday, July 6th.

Cardiff Rose Society, at Cardiff, Wednesday, July 7th.

Ealing, Acton, and Hanwell Horticultural Society, at Ealing, Wednesday, July 7th.

Sutton Amateur Rose Society, at Sutton, Wednesday, July 7th.

Bath Floral Fête and Band Committee, at Bath, Thursday, July 8th.

Hitchin Rose Society, at Hitchin, Thursday, July 8th.

Ipswich and East of England Horticultural Society, at Ipswich, Thursday, July 8th.

Hereford and West of England Rose Society, at Hereford, Friday, July 9th.

Maidstone Rose Club, at Maidstone, Friday, July 9th.

Cray Valley and Sidcup Horticultural Society, at Frognal, Saturday, July 10th.

Wirral Rose Society, at Birkenhead, Saturday, July 10th.

East Gloucestershire Rose Society, at Moreton-in-Marsh, Tuesday, July 13th.

The only fixtures of Rose Shows not in connection with the National Rose Society that have as yet reached me are the two following:—

Oxford Rose Show, Wednesday, July 7th.

Crystal Palace Rose Show, Saturday, July 3rd.

## KITCHEN GARDEN.

THE weather during the past fortnight has been very dry and warm; young vegetables have pushed up considerably, but a deluge of rain would benefit them more than anything now. Early Peas in blossom have had a thorough watering with liquid manure, and so have Cauliflowers. We do not like to make watering general in May, but if it continues dry we shall have to do so, especially in the case of all crops which are behind their usual time in being ready for use this spring. Liquid from a manure heap or a little guano dissolved in water may be used with great advantage.

CELERY.—Some of the old plants of 1885 are still retained, as the cook uses them frequently and none will be thrown away. They have been lifted from the quarter on which they were grown and are laid in by the roots in an odd corner. The ground from which they were lifted is now bearing Carrots. Trenches should be formed at once for the earliest of the young plants. If required for exhibition, plant them in single rows in trenches 10 inches deep and 3 feet apart. Give them abundance

of manure from the earth closet. Lift them with good balls of soil attached, and replant without disturbing the roots. As soon as they are planted water freely, and they will begin growing. Where it is only wanted for ordinary use two or three rows may be planted in each trench. The plants should stand 8 inches apart each way at least. Celery planted now will be in excellent condition for use by August. Tread the soil very firmly round the plants; never allow them to get dry at the root, and no loss will occur from "bolting" or flowering prematurely. Many frames are now being cleared of early Potatoes. The soil in these should be levelled, and then dibble late Celery plants in all over the surface at a distance of 2 inches or so from plant to plant. Put the lights over these for a few days, water freely, and capital plants will be produced for placing out in June or July. Plenty of water with rich and firm soil will always produce excellent Celery.

**BROCCOLI.**—Late varieties are small this spring, but the quality is good. Sutton's Late Queen has again proved the best of all. The severe weather did not injure it in the least, and at present it is excellent. Seed of this variety should be sown now to produce plants which will bear at this time next year. Seed of other varieties should also be sown in good soil as soon as possible.

**SAVOYS.**—Where many vegetables are required in late autumn and winter, Savoys are as useful as any vegetable that can be grown. They are always sure of making a crop. They are very hardy and remunerative, and such varieties as Gilbert's Universal and Green Globe are choice in quality. The seed may be sown broadcast in a small bed, or a few short rows will afford plants for a large plantation. They require rich soil at all times.

**THINNING YOUNG VEGETABLES.**—Turnips, Carrots, Spinach, and others sown some time ago are now growing freely, and it should always be a rule to thin them before any are spoiled by being crowded. When this happens the young plants are drawn, and if not completely spoiled they are generally checked and injured. As soon as all such plants can be handled they should be thinned until they stand 3 inches apart. Then, as they meet again, every other one should be taken out. A sharp boy or a woman will do very well for this work, the main point being not to delay it until too late.

**SALSAFY AND SCORZONERA.**—These are both most useful winter vegetables, and although we would not advise a cottager to sow any great quantity of either, we would recommend all amateurs to grow both, and in large gardens the absence of these crops would be unpleasant. They should be sown in much the same manner as Beetroot or Carrots. The ground should be open, moderately rich, and from 1 foot to 20 inches deep. Drills about 2 inches deep should be opened 16 inches apart, and the seed sown in them very thinly. After covering over tread down very firmly, and finish off by rolling. Mice are particularly fond of these seeds. We have known them to eat every one of them before they had time to germinate, and we advise them to be looked over every other day until the young plants are well up.

**LETTUCES.**—Those sown in the autumn and wintered at the bottom of a wall had a hard time of it in the spring, but they recovered in April, and of late we have been cutting crisp heads from them. Those raised under glass in spring have also been planted out some time ago, and are doing well, and the young plants which have been raised from seed sown in the open are now ready for transplanting. It is these open-air-raised plants which many of our readers will have to deal with, and a good number should be planted in rich soil at once. These will be ready for use in June and July, and as the weather is warm, as a rule, then, and Lettuce very acceptable, the crop should on no account be neglected, and until the end of June a pinch should be sown every ten days. As a rule there are plenty of young Lettuce plants to work with in early summer, but they often become scarce by August and September, and care should be taken that the supply is maintained.

**EARTHING UP.**—All Potatoes which are through the ground should be earthed up. If the soil is poor sprinkle a little artificial manure along the side of each row before earthing, then with a drag hoe draw the soil up against the stems to form a broad ridge. Early-planted Cauliflowers and Brussels Sprouts should also be earthed up. Before doing so last year we sprinkled a small handful of guano round each, and we did not lose a single plant afterwards from worm at the root, clubbing, or any cause. The grubs evidently did not appreciate the guano, but the Cauliflower did.

**KIDNEY BEANS.**—A few more of both the Dwarf and Runner varieties should be sown to succeed the first, as through unfavourable weather and other causes these are not always a success. Now, however, they may be sown with every certainty of their doing well, as the young plants will not be through the soil until about June, and then their growth will be sure and rapid.

**HOENING.**—Weeds are worse than useless in the vegetable garden, and they should never be allowed to become large or go to seed. The best way of treating them is to hoe them down when the soil is dry and when they are small. If allowed to grow and seed now they will be a constant trouble during the whole season, but if checked in time they will soon be exterminated, labour will be saved in the autumn, and the garden will leave a neat clean appearance.

**PICKLING ONIONS.**—These can hardly be too small, and they should be sown later than the others. Now is a good time to put them in. Sow them broadcast in a narrow bed, and give them a very poor soil, as this is the only means of keeping the bulbs small.

**TOMATOES.**—Plants intended for open air culture should now be placed outside, but do not plant them out for a week or two yet. If they can only be hardened off and planted out without receiving a check there

is no danger of failure afterwards. Indoor plants now require copious supplies of water. Those bearing fruit should have a quantity of liquid manure three times weekly. Admit plenty of air to plants on which the fruit is ripening. Rub the side shoots off frequently, and confine the plant to one or two main stems.

#### FRUIT FORCING.

**FIGS.—Early-forced Trees in Pots.**—Take advantage of mild days to increase ventilation, and expose the fruit as much as possible to the sun. When the first crop is gathered, as will soon be the case with trees in pots started in November, return to the treatment applicable to trees swelling off crops. Red spider having gained a footing, determined measures must be taken for getting rid of it by syringing twice a day, or washing the leaves with a weak solution of softsoap, 2 ozs. to the gallon of water, on fine evenings twice a day until new growth is being made freely. Where the second crop has set thickly on free-bearing varieties, such as Brown Turkey, the best of Figs for forcing, thinning should be carried on liberally, as there is little danger of the trees casting their fruit after this period provided they receive generous treatment. With a view to a succession of fruit it may be left of different sizes on the same branch, but it is useless trying to take more than two crops in a season, as the trees must have rest through September and October. Growth after this period will necessitate frequent attention to stopping and training, as the best Figs are always produced on vigorous young shoots fully exposed to sun and light.

**Succession Houses.**—When the fruits are swelling for ripening a higher and drier atmosphere will hasten maturity; but care must be taken to afford plentiful supplies of tepid liquid manure to the roots, and to syringe the foliage regularly, as any sudden check might prove injurious. As the Figs approach ripeness it will not be advisable to wet them if it can be avoided, nor is it necessary, as atmospheric moisture can always be secured by keeping the mulching, walls, and paths properly moistened, and this can be prevented from condensing on the fruit by maintaining a steady circulation of air with gentle fire heat. When grown in a hot, dry house the Fig soon becomes infested with red spider and scale, and as a natural consequence the ripening period is shortened, and the trees simply rest because they are exhausted; the second crop is consequently puny, rusty, and unsatisfactory; but feed them liberally, ventilate freely, and syringe as often as they are divested of ripe fruit, and they become perpetual bearers. To keep a Fig in constant bearing it must be continually growing, and for this reason the extension system answers the purpose best, as the leading shoots are allowed to extend without topping until they reach the extremity of the trellis, when they are cut away at the winter thinning to make room for others succeeding them.

**Cold Houses.**—Fig trees in these, notwithstanding the nngenal spring, seem to be showing plenty of fruit, last season being highly favourable to the ripening of the wood, and with favourable weather they will afford an acceptable supply of fruit in August and September. Assuming the roots are confined to reasonable limits inside the house, and that the borders are concreted and thoroughly drained with broken bricks and old lime rubbish, a material upon which they seem to thrive, they will require very copious supplies of water and syringing twice a day. Except in cloudy weather the afternoon syringing may be dispensed with, and in bright weather it may be performed early with all the solar heat that can be shut in to insure the proper drying of the foliage before nightfall. The young growths in these structures should be trained a good distance apart, as overcrowding impedes the free passage of light and warmth, so essential to the ripening of the fruit and wood. Close stopping in late houses is not a good plan, as it results in the production of a number of late growths which do not get properly ripened before the leaves fall. The safest course is to secure firm short-jointed wood, and allow the points to grow up to the glass, a position in which they will form abundance of embryo Figs ready for swelling in the spring.

**MELONS.**—As pits and frames in which Potatoes, &c., have been grown become vacant, they may be prepared for Melons. Root-bound plants are not good, and large overgrown plants receive such a check on removal that preference should be given to healthy samples stopped and in 4 and 5-inch pots. The soil in which the Potatoes, &c., are grown having been cleared out, turn the leaves and add some fresh ones to raise the bed to within the required distance of the glass, allowing a few inches for settling, treading them firmly at the time of putting them in the pit. The turning and addition of fresh leaves to the beds will insure a gentle warmth and give the plants a start. A few inches of decayed manure may be placed on the leaves, and then the soil, a couple of barrowloads in the centre of each light to form the hillocks and extending outwards so as to cover the bed, and yet leave a hillock in the centre about a foot high with a flattened top. When this has been in the frame two or three days tread all down firmly, hillock as well as the other part, and if these are reduced in height so as to have a depth of 9 or 10 inches of soil, and there is a slight incline from them outwards, it will be all the better, so as to keep the water from the neck or collar. Earthing these beds will not be necessary. The plants having previously been well watered, so as to cause the roots to leave the sides of the pot and not necessitate watering at planting, put out; press the soil firmly around each, and should the sun be powerful shade for a few days until they become established, after which it should be discontinued.

Other plants should now be raised to place in frames, which will shortly be cleared of bedding plants. Syringe plants when hot water is at command during bright weather, but early in the afternoon will be sufficiently often for plants in structures not so heated. Ventilate early in the morning to prevent the foliage being scorched by the sun shining on it whilst covered with moisture or the leaves full of moisture, for the ventilation

will accelerate evaporation. From 7.30 to 8 o'clock is a proper time to ventilate, but it will need to be regulated by the weather and aspect of the houses. Half-past three to four o'clock on bright days will be soon enough to close the house. Those in flower will need a somewhat dry and airy atmosphere, the blossoms being fertilised at midday until they have set their fruit, after which they should be subjected to a moist atmosphere, with a minimum temperature of 70° and a maximum of 90° to 95° with sun. Three or four fruits, according to the strength of the plants, will be sufficient on each, all others being removed as they appear. Plants with the fruit ripening will require a high temperature—70° to 75° artificially, and 85° to 95° by day from solar influence, with a gentle circulation of air constantly, and moisture must be kept from the atmosphere.

#### THE FLOWER GARDEN AND PLEASURE GROUND.
